The important evidence appearing to favor the hypothesis that all the rocks occur in flows is as follows: (1) The locus of each rock is horizon like. For example, the lower rhyolite is encountered at depths averaging about 1000 ft., over an area of at least a square mile. Its surface, except where it is faulted, is seldom steeper than hill slopes, and is chiefly flat or horizontal. (2) Materials closely resembling stratified volcanic tuffs occur abundantly on the upper contact of the lower rhyolite, and less abundantly on the upper contact of the upper rhyolite. (3) The contacts between the supposedly intrusive and intruded rocks are, when unfaulted, most often notably straight and regular. Nowhere have the so-called intrusives been conclusively proved to invade by means of offshoots the rocks which they have supposedly intruded. The interpretation of irregularities of contact as proof of intrusion is made difficult by the abundant faulting, and by the possibility of inter-flow erosion. (4) The andesitic cover has, over a large area, rigidly confined the rocks which underlie it. The lower rhyolite, a rock having a characteristic and unmistakable appearance, has been proved to occur on the surface only in the territory considerably north of the producing mines, and there in very small and scattered bodies which may be inclusions. (5) The productive veins in certain places pass without diminution either in size or richness from the earlier andesite down into the upper rhyolite. (6) In many places near the top and near the bottom of the upper rhyolite, there occurs an extraordinary igneous breccia, often many feet thick and crowded with foreign inclusions; the matrix is rhyolitic, and the rock looks exceedingly like a flow breccia. The upper portion of the lower rhyolites has numerous but less abundant inclusions. (7) The rhyolites, though containing abundant inclusions, and, among them some which are andesitic, have never yielded inclusions which can be positively identified as belonging to the earlier or later andesites. (8) The andesites are free from inclusions of all sorts; therefore their freedom from inclusions of rhyolite is no indication that they are older than the rhyolites.

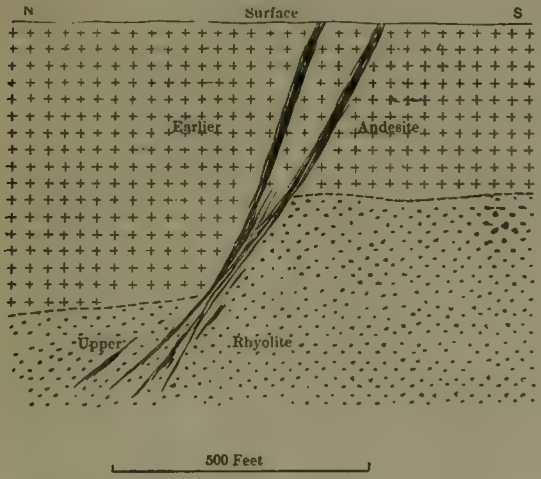
The evidence supposedly favoring the hypothesis that some of the rocks are intrusive is as follows: (1) In the rhyolites, a banding resembling flow structure sometimes follows irregularities in the contact. (2) The rhyolites ocasionally have on their contacts with the andesites knob-like and wedge-like projections, looking like intrusive shapes. (3) In certain places the calcitic andesite is separated by rhyolite from the later andesite with which it is supposed by Spurr to be identical. In certain places the earlier andesite is separated by upper rhyolite from a rock called glassy trachyte, with which Spurr supposes it to be identical. (4) The profitable veins often disappear or weaken when they reach down to the lower contact of the earlier andesite.

---

*Abstract of a paper presented at the San Francisco Meeting of the American Institute of Mining Engineers.

It must be granted at the outset that the disposition of the rocks in horizons creates the presumption that they are flows. Most of the shafts penetrate similar rocks in similar succession. Thus, the lower rhyolite, so far as is known, underlies the whole district; the calcite andesite almost everywhere covers the lower rhyolite; and above these rocks come, in order, the upper rhyolite, the earlier andesite, and the later andesite. The individual sheets of rock have many irregularities in thickness; these, however, are satisfactorily attributable to interflow erosion and to faulting.

Again, if we conclude that the earlier andesite is the oldest rock in the district, we must conclude also that it has been floated up by the intrusive underlying rocks to a height of at least 1000 ft., and possibly to a much greater height. (The lower contact of the lower rhyolite is not known.) During the process of floating up, the andesite has retained over an area of at least a square mile, its integrity and approximate horizontality.



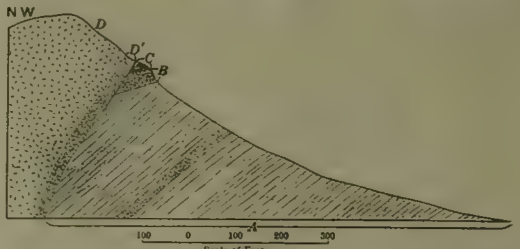
DOWNWARD EXTENSION OF TYPICAL VEIN INTO RHYOLITE.

A general view, then, of the large features of rock distribution affords strong evidence in favor of the theory of extrusion. Nevertheless, it is conceivable that pseudo-flows might result from intrusion, and this evidence is, therefore, by itself, inconclusive.

If the large facts of rock distribution fail to furnish conclusive evidence of the origin of the rocks, this evidence must be sought in the details of the rock contacts. In general, there are certain details of rock contacts whose testimony must be accepted as unimpeachable. One such detail is the existence at contacts of volcanic tuffs; genuine tuffs being proved to exist between layers of volcanic rocks, it is difficult to conceive of evidence, however abundant, which would prove that the layers are not flows. It becomes, therefore, a matter of extreme importance to determine whether or not in Tonopah the supposed tuffs are genuine. Burgess, who discovered them, believes that they are. Spurr believes that they are not. That they are tuff-like, is beyond doubt. They are somewhat soft; they possess stratification, marked by alternating bands of coarse and fine fragmental material; they cleave easily along the junctions of these bands; they lie with their structure parallel with the rock contacts. If they are not true tuffs, resulting from surface deposition, then they are conceivably attributable to one or both of two processes—flow-banding (the arrangement of inclusions along flow-lines) and movement-banding. Spurr's conception of their origin is expressed in the following: "* * * brecciated and granulated rock is often layered by the fault-movement and fault-pressure, so that it assumes all the appearance of certain varieties of surface-formed detrital tuffs."

Microscopic examination of thin sections of specimens from the Mizpah 700-ft. level yields conclusive evidence against the possibility of the production of the supposed tuffs either by flow-banding or movement-banding. (1) The tuffs are made up of sharp-cornered fragments, often crowded closely together, and are typically clastic. (2) They are distinctly layered; layers of coarse material alternate with layers of fine material, with no gradation from coarse to fine. (3) The abundant quartz phenocrysts, with one or two exceptions, when revolved in polarized light, extinguish with much suddenness. The wavy extinction, which is the invariable characteristic of strained quartzes, is strikingly absent. That a sorting out and sharp separation of coarse from fine should result from flow or movement-banding is, of course, incredible. And the significance of the unstrained quartz phenocrysts cannot be questioned. Indeed, the tuffs are so life-like and their detrital origin so obvious that their import would be ordinarily accepted as a matter of fact.

The supposedly intrusive contacts of rhyolite with other rocks at no place seen by me offer incontestable evidence of intrusion. Before such proof can be accomplished, it is necessary to prove that the irregularities were not caused by faulting, or by inter-flow erosion, or by both. Now, in localities of extensive rock alteration and abundant faulting, such proof is impossible; indeed, here the proof that the irregularities were actually caused by faulting is frequently possible. The rhyolite at certain places possesses a banding which follows to some extent irregularities of the contact, and which sometimes looks like flow-banding, and might suggest intrusion. I have failed, however, to find any such place where the evidence of intrusion was unequivocal. Usually, the banding is irregular and very discontinuous. It is quite as often oblique to the contact as parallel with it. Moreover, if contact-movement, as Spurr believes, can produce tuffs, it is very easy to conclude that it can produce apparent flow-structures.



(From *Professional Paper No. 42, U. S. Geological Survey.*)

A. Finely stratified Siebert tuffs (lake-beds) with occasional layers of rounded pumice fragments or water-worn lava.

B. Basaltic agglomerate with bombs, capped by solid basalt.

C. Basalt.

D. Brougher dacite, intrusive neck.

D'. Glassy marginal facies of dacite.

VERTICAL CROSS-SECTION OF SOUTHEAST SIDE OF SIEBERT MOUNTAIN.

The usual restriction of nearly all the probable ore deposits to the earlier andesite is one of the most interesting facts of ore occurrence with which I am familiar. In certain cases, the ore ends abruptly when it comes down to the lower contact of the andesite. In other cases, it extends down into the underlying rhyolite, ultimately, however, weakening and dying out. Occasionally, as seen in the figure, it survives for a time with a hanging wall of andesite and a foot-wall of rhyolite, ceasing shortly after it passes entirely into the rhyolite. Lastly, it passes from andesite to rhyolite without change.

To explain the superior productivity of the andesite, many hypotheses are possible: (1) The andesite is the earliest rock; the chief ore-mineralization followed it and preceded the other rocks. (Spurr's hypothesis.) (2) The source of the ore minerals may have been the andesite itself or the upper rhyolite. (Suggested by Burgess.) (3) The ore was deposited largely by metasomatism. The various rocks, particularly the upper rhyolite and the earlier andesite, present great contrasts in texture. Certain textural and chemical properties possessed by the andesite caused it to be more favorable to the precipitation of the ore minerals than the other rocks. Or the andesite was more favorable to the formation of initial channels than the other rocks. (4) The path of travel of transporting agents was mainly along the andesite-rhyolite contact and upward into the andesite. (5) Ore deposition was a superficial phenomenon, effected through the decrease of heat and pressure near the surface, or through other superficial agencies. The andesite, at the time of ore deposition, was the surface rock, and, therefore, received the bulk of the ore-mineralization. (6) Post-vein faulting at the contact between upper rhyolite and lower andesite in some instances caused the disappearance of the vein at the contact. (7) Ore-mineralization occurred after the eruption of the earlier andesite and in cooling-shrinkage cracks in that rock.

Spurr, as has already been made clear, accepts the first of these hypotheses and, apparently, rejects the others. The fact that the ore frequently extends down into the rhyolite, he explains by a supposition of several periods of mineralization, of which the first and most important was earlier, and the others later, than the rhyolite. Veins contained entirely in andesite belong, then, to the first period; veins in rhyolite, or in both rhyolite and andesite, belong to later periods. That several periods of mineralization did exist is probably true. The assignment, however, of a particular vein to a particular period is often impossible. There is no mineralogical distinction whatever to be made between many veins which, according to the hypothesis, should belong to separate periods. The remaining six hypotheses cannot be easily cast aside. To prove any one of them would be difficult; to disprove would be even more difficult. Yet so long as they stand as possible explanations of the localization of the ore deposits, they must offer impassable barriers to the acceptance of the hypothesis just now considered.

Siebert mountain looks like a succession of flows, but Spurr's interpretation, shown above, regards it as partly intrusive. The fact of the matter is, however, that the supposedly intrusive rhyolite (or dacite), just above its contact with the basalt, has a very well-marked and nearly horizontal flow-structure—a fact scarcely compatible with the idea that the contact has the character shown in Spurr's section. That the rocks of the productive part of the Tonopah mining district are flows lying in the order of their deposition is proved by the occurrence of volcanic tuffs at the contacts whose interpretation has been in dispute. The other available evidence in some instances supports, and in no instance contradicts, this conclusion. There is no good reason, then, for the belief that the rocks underlying the earlier andesite are younger than the chief productive mineralization. Exploration in these rocks is accordingly relieved of the discouragement which would attend this belief.

Mineral Production of Philippines in 1910

The bulletin on Philippine Mineral Resources for 1910 has been unavoidably delayed but is now in the press. In advance of its publication, the following statistics are given:

Total metallic production, including coal	₱505,138
Total non-metallic, chiefly structural material	1,541,031
Total mineral production	₱2,046,169
Total gold production	308,860
Value of iron produced	20,023
Value of total coal production	176,255

The largest amount of gold was derived from Ambos Camarines; the iron was entirely derived from small native mines.

Electrical Iron Smelting in Sweden

By T. D. Robertson

*The success attained in smelting magnetic concentrate at Trollhattan is of great interest. The design of shaft now employed is not considered suitable for the purpose, being too narrow, but in spite of this 65%, of fine concentrate caused no inconvenience in working. The inventors of the furnace are of the opinion that with a specially designed shaft, all fine concentrate could be smelted alone. Iron sands and lean magnetites, which are easily concentrated, but which are expensive to nodulize or briquette into a form suitable for blast-furnace smelting, are of frequent occurrence, and that where these are within easy reach of water-powers, there seems to be a good field open for electric smelting. Haanel, in his report on the experiments made at Sault Ste. Marie, mentions that no difficulty was experienced in smelting titaniferous ores electrically, and it is interesting that the Swedish experience bears this out, although no ores were used with more than 0.8% TiO_2. The electric smelting of ores with high sulphur content is another problem. Haanel was successful in producing low sulphur iron from sulphurous ores, but in Sweden there are practically none of these ores mined, so that this point was not confirmed on a large scale at Trollhättan; however, there can be little doubt that the electric furnace, with its reducing atmosphere and basic lining of the hearth, permitting as it does of the use of a slag rich in lime, offers the best method of producing sulphur-free pig iron from ores containing that unwelcome element.

The pig iron produced by the furnace was sent to various Swedish iron works for conversion into steel in open-hearth furnaces. The characteristic feature of electric pig iron is its freedom from oxides; and in consequence electric pig of normal silicon content (say, 1% and over) takes a longer time and more ore to convert into steel than ordinary blast-furnace gray iron. Low-carbon electric pig iron, however, is found to give surprising results, charges made up of 50% of this iron and 50% of scrap producing hot fluid steel with considerable saving of time over ordinary practice. As was to be expected, the open-hearth furnace managers looked somewhat askance at this iron at first, as they knew the disastrous effect of using low-carbon iron full of holes from the blast-furnace; however, after giving it a trial, the workmen asked for more, as they said that the furnace worked better and more rapidly with the new pig iron. Fortunately for the electric furnace in Sweden, it is more economical to make the white iron, that the steel-makers prefer, than to make high-silicon gray iron. Thus it may be maintained, on the strength of the experience gained, that for the open-hearth process, high silicon contents are detrimental rather than advantageous, while in the blast-furnace pig iron a certain quantity is necessary to neutralize the defects of a reduction process less perfect and ideal than that employed in the electric furnace. The quality of the steel produced has been thoroughly tested by making it up into various products and comparing it with steel made from Swedish charcoal blast-furnace iron. In no case was the new steel inferior, and, from the most recent reports to hand, it was in several cases decidedly superior.

The Trollhättan furnace was shut down at the end of May of this year in order to make certain alterations suggested by the results of its six months' campaign. Two of these deserve mention.

(1) Since the furnace was designed, the manufacture of large carbon electrodes, of high conductivity, has made great progress. It is now possible to obtain cylindrical electrodes of 600-mm. diameter, fitted with screw joints. These have recently been installed at Trollhättan, and result in two considerable improvements, the first one being that the loss due to stump ends is done away with, as when an electrode becomes too short, a new one can be

---

*Excerpt from a paper presented before the American Electrochemical Society, Toronto, September 21 to 23.

screwed above it. The second one is that the electrical contact can be made at the point where the electrode enters the roof, in this way saving about 40 kw., which with the old arrangement was lost, due to the resistance of the whole length of the electrode through which the current had to pass. This new arrangement will permit of the furnace taking 3000 hp. instead of 2500 horse-power.

(2) The other important alteration is in the gas-circulating arrangement. The old dust-catcher was not very effective, as only very fine dust is expelled from the furnace. The result was that the dust collected in the centrifugal fan, and had it not been that this was kept fairly clear by a jet of water, would have choked up the blades in a few hours; as it was, the fan had to be stopped and cleaned every week. Now a water-scrubber takes the place of the dust-catcher, and a fan on the ground floor blows the cleaned gas into the furnace, and the other fan being held in reserve. At the present time the following 'Electrometall' furnaces are either working or in course of erection:

Sweden.	Hp.
Trollhättan, one furnace	3,000
Domnarfvet, one furnace	4,000
Hagfors, two furnaces (3000 hp. each)	6,000
Norway.	
Tyssedal (Hardanger), two furnaces (3500 hp. each)	7,000
Arendal, two furnaces (2500 hp. each)	5,000
	25,000

In these newer furnaces, 3-phase current is used, and by means of three single-phase transformers low-tension current is furnished to six carbon electrodes. Owing to the recent improvements in electrode manufacture and furnace design, it is now possible to construct units up to 6000 hp. which it is expected will work for two years without serious repairs to the hearth. Rather more than three metric tons of pig iron are produced by the electric furnace per electrical horse-power year, using one ton of charcoal for the reduction of the ore. The blast-furnace uses about three times this amount of fuel per ton of iron, so that in Sweden, where, owing to the demand of wood for the pulp industry, the price of charcoal is yearly advancing, there is a great field open for electrical smelting on account of the saving in fuel. The furnaces in Norway have a somewhat different form of shaft, as coke is the fuel employed for smelting. The volume of the shaft is smaller, but its diameter is greater, than the corresponding shaft of a charcoal furnace. The coke in the charge gives a greater conductivity, so that a lower tension has to be used. In the London correspondence of the October 14th issue of the *Mining and Scientific Press*, interesting details of the application of the electrical furnace to the smelting of complex sulphide ores are given.

Metal Mining in Washington, 1910

The total value of the gold, silver, copper, and lead from the State of Washington in 1910, according to C. N. Gerry, of the U. S. Geological Survey, was $968,249, against $448,966 in 1909. The output for 1910 was the largest in gold, silver, and lead and the smallest in copper for six years. The production of gold in 1910 was $788,145, against $362,051 in 1909; that of silver was 205,345 oz. valued at $110,886, against 79,488 oz., valued at $41,334; that of copper 86,918 lb., valued at $11,038, against 255,134 lb., valued at $33,167; and that of lead 1,322,278 lb., valued at $58,180, against 288,700 lb., valued at $12,414. The number of producing mines in Washington increased from 11 placers and 35 deep mines in 1909 to 21 placers and 55 deep mines in 1910. The placers produced, however, only $3859 gold in 1910. The deep mines produced 59,209 tons of ore in 1910, an increase of 22,901 tons over the output of 1909. The Republic district, in Ferry county, produced the greater part of the gold and silver in Washington, and mines in Stevens county produced nearly all the copper and lead. The Republic district alone produced gold, silver, copper, and lead valued at $813,686 in 1910.

Ore Deposits in South Central Porto Rico

Peter Nelson, an experienced prospector and miner from the Western States, reports that he has recently discovered a mineral belt several miles in area on the southern side of Porto Rico in the municipal district of Guayama, about the central part of the island. The veins are traceable from the bottom of the foothills to a distance of about six miles from the coast and have variable strikes and dips, although many seem to have a northwest strike, with a dip to the southwest. The veins rarely project above the surface, and there is nothing to indicate them but the foot-walls, which are much harder than the hanging walls or the usual country rock. These veins have numerous shoots of high-grade oxidized and sulphide ores, chiefly galena, which can be uncovered at many of the projecting walls by removing from 4 to 10 ft. of loose earth and shattered rock, which has crumbled from the harder foot-wall. The north and south veins also contain galena, but are of a different character, being associated with schist and limestone, and in many places outcrop high above the surrounding country. On this projecting rock there can sometimes be seen fragments of galena which is 'frozen' to the wall-rock. This can also be found on the hillside for some distance from the outcrop from which it has floated. None of these have been developed, so far as known, and probably never were discovered until the present time, but in the same belt there are two veins that were discovered and developed in a crude way during the Spanish régimé. These veins have an easterly strike and show some high-grade ore. None of the old excavations are deeper than 20 ft., all of the work was open-cut, and the dumps show that nothing but the coarsest and hardest pure galena was saved, for all the carbonate ore has been thrown on the waste dumps. One of these old Spanish claims has a shaft to a depth of 60 ft. on a vein that has a dip to the northeast, in which there was a shoot of galena, but when a depth of 20 ft. was reached, the galena entirely disappeared and there was nothing left of the shoot but a small streak of hard quartz carrying some sulphides, and at intervals showing copper stains. An adit was driven under a shallow hill and it was discovered that the ore reached the same depth below the surface at that place. The problem was carefully studied and it was observed that the shoots had come from another vein that joined them near the surface and had a directly opposite dip. So the shaft will be sunk on the same dip, and cross-cuts will be driven through the separating dike to cut the vein that has ore-shoots.

The shaft is only to a depth of 60 ft. and is the deepest shaft known on the island, sunk for mining purposes. The showing at present is very promising, and there is apparently no reason why this district will not turn into a flourishing mining centre within a short time, as the ore from some of the veins which average a foot in width, assays as high as 4.03 oz. gold and 19 oz. silver, besides the lead there is in the ore. Shipments of two small lots, already made, show the ore to run as high as 55% in lead, free from zinc. The first shipment proved to be 49% lead and the second 55%, as it was extracted from a lower level and more free from surface dirt. Veins have also been found from cross-cutting on the surface, 10 ft. wide where they were cut, and the returns on the assays are favorable, as the ore carries from $5 to $7 in gold besides the lead. Most of the claims are at a good elevation, so that they can be worked by adits to a considerable depth.

The district is being explored by Messrs. Nelson, Link, Shanton, and associates, who are doing development work and are finding good ore in many places. The properties on which the work is being done are held by option. There has not yet been sufficient work done on any of the properties to determine the extent of the orebodies. The gentlemen mentioned have now filed with the Secretary of Porto Rico articles of incorporation of the Porto Rico Mines Co. Mr. Shanton, who has been assisting in the exploitation of the development work, is Chief of the Insular Police of Porto Rico, having for five years held the same position on the

Isthmus of Panama, and is well known among all the business men and Government officials on the island of Porto Rico. It is to be hoped that this discovery may prove but the forerunner of many others and eventually lead to the development of Porto Rico as an important mineral region.

September Copper Review

By M. E. Appelbaum

Very little of interest happened in the month of September to affect copper one way or another. The copper market exhibited great strength in the face of the severe declines in securities; which, in my opinion, is due to the fact that the entire visible supply is practically controlled by one interest. While I am not at all enthusiastic as to the copper prices during the coming year, I am nevertheless inclined to think that during the next few months business conditions will be sufficiently good to reduce the visible supply and, of course, cause temporarily higher prices. Production for the month of September shows that temporarily, at least, the production will range about 115,000,000 lb., against which there should be combined deliveries of about 125,000,000 to 130,000,000 pounds.

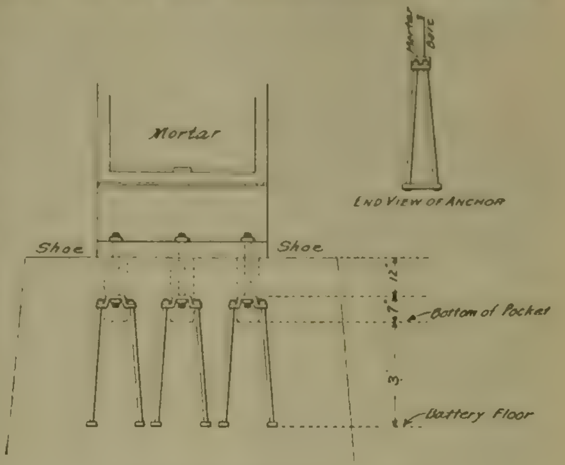
Bearing Metal

When white bearing metal is repeatedly remelted, according to the researches of E. Heyn and O. Bauer, published recently in *Mitt. kgl. Material-prüfungsamt.*, some tin and antimony are lost because of the readiness with which these metals are oxidized at the melting point. The relative amounts of tin and antimony are not changed by the remelting, but the percentage of copper is slightly increased. No appreciable changes in hardness or strength result therefrom. Much more important than the slight changes in chemical composition which result from remelting, is the nature of the cooling which the casting receives. Rapid cooling, in general, increases the hardness, the resistance to hammering, and resistance toward pressure. Presumably there is a corresponding change in the suitability of the metal for bearings. To a certain extent the mechanical properties can be judged by the appearance of the fracture, provided the chemical composition does not vary much from the usual specifications. Rapid cooling produces a fine-grained structure. A more accurate conclusion can be drawn from the microscopic study of a polished specimen. The appearance of the fracture does not give any idea of the chemical variations in the bearing metal, but these can be determined by chemical analysis. The addition of magnesia and aluminum as deoxidizing agents causes a slight increase in hardness, but the mechanical properties are not materially changed by the small amounts of these elements that would be added for the above purpose. In melts deoxidized by aluminum, some efflorescence of Al_2O_3 was observed, but it could not be determined whether this was harmful. Since the change in chemical composition by remelting five times was slight, it does not seem necessary to add any deoxidizing agent. The chief requisite in making bearings is to be sure that the casting temperature is not too high and that the cooling is sufficiently rapid.

By regulating the velocity at which red metal castings cool an important influence is produced upon the mechanical properties of these bronzes. Rapid cooling from above 782° C. increases the hardness and tensile strength, and for this reason sand molds do not produce the best results. The size of the casting influences the rate of cooling in sand molds and sand castings are porous. The change in chemical composition which the alloy undergoes on remelting is slight with copper-tin alloys low in zinc, although there is a tendency for some of the tin to oxidize and remain in the alloy as oxide. By repeated remelting, the hardness and tensile strength are not much affected, but the elasticity and resistance to shearing stress and to shock are diminished. The influence of arsenic upon the temperature at which crystals separate out from the melt is only felt when the arsenic content is considerable.

Battery Foundations

A good form of battery foundation is seen in the accompanying sketch. The anchors are bedded solidly in the concrete at about the level of the mill floor and the concrete continued solidly up to 7 in. below the top of the caps. Then the pocket mold is placed and the block completed. The short mortar bolts prevent any drifting of the mortar, and with the modern high base, deep trough mortars can be easily removed or replaced in case of breakage. In the smaller sketch the details of the construction of the anchor bolts is shown. Each complete anchor consists of two foot plates, 1 by 3 by 10 in., hot-riveted to the four anchor rods, 1 in. by 3 ft., which are provided with a thread and hexagon nut at the top. The cap plate is 1 by 5 by 15 in., bent to the shape shown. The mortar bolt is 1¾ in. by 2 ft., provided with a square nut at the bottom and a hexagonal nut at the top. The mold for the pockets can be readily made of wood and sheet iron.



CONVENIENT BATTERY FOUNDATION.

The Trinity River Basin

The gold-bearing gravels of the Trinity River basin, California, form the subject of a brief report by J. S. Diller, of the United States Geological Survey. The basin is especially noted for its placer mines, which have been worked since the early fifties, and it contains the La Grange mine, the largest hydraulic mine now in operation. In tracing the early geologic transformations of the region Mr. Diller states that there were many advances and retreats of the glacial ice through a long period, and shows that the movement of the glaciers were closely related to the development of the valley terraces during the last cycle of erosion, when the modern streams were trenching their present valleys deeply below the general level of the plateau. Glaciers, Mr. Diller says, are 'gravel mills,' and the gravel and boulders of the till of the earlier glaciers, having thoroughly decomposed, liberated all the gold for concentration by stream action in the gravels capping the terraces of the present streams. In thus initiating the concentration of gold glaciers have a distinct economic aspect.

Mr. Diller discusses three distinct cycles of erosion and the resulting concentration of gold in the different types of gravels of the area, and past and present development of mining. Certain of the deposits, he believes, are worthy of careful prospecting, especially the beds of gravel on the bars and benches of the upper part of Trinity river. If the dredges already started at Trinity Center and Poker Bar prove as successful as they promise, he says, a new impetus will be given to placer mining in the basin. A copy of this report (contained in Bulletin 470-B) may be obtained by application to the Director, United States Geological Survey, Washington, District of Columbia.

Japan Excursion, American Institute of Mining Engineers

On Sunday, October 15, the members of the Institute and their guests, to the number of about 200, made an excursion to the Bohemian Grove, on Russian river in Sonoma county. After an hour spent in strolling about the grove, lunch was served, followed by an hour of music in the leafy amphitheatre. The party returned to San Francisco in the early evening, enthusiastic over the quiet beauty of the spot. On Monday evening the local members of the Mining and Metallurgical Society entertained the visiting members and prominent members of the Institute at a dinner at the Fairmont hotel. The dinner was followed by a discussion of the Alaska land laws, which was opened by H. Foster Bain, and in which Dr. Raymond, George Otis Smith, E. W. Parker, W. R. Ingalls, Charles G. Yale, M. L. Requa, R. Kanda, W. C. Ralston, and W. L. Saunders joined.

On Tuesday morning the members of the Institute who are to visit Japan sailed on the *SS. Manchuria*, Joseph Struthers, the secretary, being in charge of the party, which is accompanied by Reiji Kanda, who came to San Francisco as the representative of the Japanese mine owners' association. The provisional itinerary, so far as it can be fixed in advance, is as follows:

Tuesday, October 17.—Leave San Francisco.

Monday, October 23.—Arrive at Honolulu in early morning. 9 a.m., automobiles visiting Pearl Harbor, Pali, aquarium, and Bishop museum. 12 noon, luncheon at Moana Loa hotel. Late afternoon, leave by *SS. Manchuria.*

Friday, November 3.—Morning, arrive Yokohama. 1:30 p.m., leave Yokohama. 2 p.m., arrive Tokyo, Imperial hotel (Institute headquarters while in Japan). Evening, 9 p.m., ball, tendered by Minister of Foreign Affairs, in honor of the Emperor's birthday.

Saturday, November 4.—Morning, in Tokyo. Noon, luncheon, Hotel Seiyoken, Uyeno Park. 2 p.m., reception by committee, Hotel Seiyoken. Evening, dinner tendered by Baron Iwasaki, Baron Mitsui, and Mr. Furukawa.

Sunday, November 5.—Morning, in Tokyo. Noon, luncheon, Imperial hotel. 1:30 p.m., reception, Mining Institute of Japan, Maple Club. 3:30 p.m., reception, Minister of Agriculture and Commerce, Nobles Club. Evening, Empire theatre, invitation of Reception Committee.

Monday, November 6.—8:50 a.m., leave Tokyo. 12:40 a.m., arrive Nikko, Nikko hotel and Kanaya hotel. 2 p.m., Nikko Copper Works, Furukawa Mining Company.

Tuesday, November 7.—Nikko.

Wednesday, November 8.—1:50 p.m., leave Nikko. 5:35 p.m., arrive Tokyo, Imperial hotel.

Thursday, November 9.—Section A (one-half of party): 9 a.m., leave Tokyo; 10:08 a.m., arrive Kamakura, Kamakura hotel; visit Kamakura temples and Yenoshima islet. Section B (other half of party): 9:10 a.m., leave Tokyo; 10:41 a.m., arrive Kozu, electric car and ricksha to Miyanoshita, Hakone, Fujiya hotel, Miyanoshita.

Friday, November 10.—Section A: 8:15 a.m., leave Kamakura; 9:05 a.m., arrive Kozu, electric car and ricksha to Miyanoshita, Hakone, Fujiya hotel, Miyanoshita. Section B: 9:25 a.m., leave Kozu; 9:55 a.m., arrive Fujisawa (Kamakura); visit Yenoshima islet and Kamakura temples, Kamakura hotel.

Saturday, November 11.—Section A: morning, leave Miyanoshita for Kozu in time for 10:10 train. Section B: 9:15 a.m., leave Kamakura; 10:07 a.m., arrive Kozu. Sections A and B: 10:10 a.m., leave Kozu; 8:40 p.m., arrive Kyoto, Miyako hotel and Kyoto hotel.

Sunday, November 12.—Kyoto.

Monday, November 13.—8:10 a.m., leave Kyoto. 9:35 a.m., arrive Nara. Noon, luncheon, Nara hotel. 4:55 p.m., leave Nara. 6:17 p.m., arrive Kyoto, Miyako hotel and Kyoto hotel.

Tuesday, November 14.—7:30 a.m., leave Kyoto. 8:27 a.m., arrive Osaka, reception by Mr. Fujita. 1:30 p.m., leave Osaka. 2:38 p.m., arrive Suma, reception by Mr. Sumitomo at his villa. 4:35 p.m., leave Suma. 4:51 p.m., arrive Kobe. Evening, dinner at Oriental hotel. 10 p.m., embark *SS. Omegaka Maru.*

Wednesday, November 15.—Early morning, arrive Shisaka island; visit Sumito's Smelting Works. Forenoon, leave Shisaka, sail through Inland sea. Evening, arrive Miyajima; quarters on steamer.

Thursday, November 16.—Morning, Miyajima (said to be one of the three most beautiful places in Japan). Afternoon, leave Miyajima by *SS. Omegaka Maru.*

Friday, November 17.—Daybreak, arrive Moji. Morning, at Wakamatsu; visit Imperial Iron Works. Afternoon, return to Moji; quarters on steamer.

Saturday, November 18.—7:10 a.m., leave Moji by train. 10:46 a.m., arrive Omuta; visit Miike coal mines. 5:30 p.m., leave Omuta. 9:10 p.m., arrive Moji; quarters on steamer.

Sunday, November 19.—9:50 a.m., leave Shimoneseki by train.

Monday, November 20.—2:30 p.m., arrive Yokohama, Grand hotel.

Tuesday, November 21.—Morning, leave Yokohama by *SS. Siberia.*

Thursday, December 7.—Arrive San Francisco.

Among the members of the party are Mr. and Mrs. H. Foster Bain, Mr. and Mrs. George B. Berger, Mr. and Mrs. LeRoy Brewster, Mr. David W. Brunton, Mr. and Mrs. Will L. Clark, Mr. and Mrs. F. H. Daniels, Mr. and Mrs. Henry S. Drinker and daughters, Mr. Carlos F. Galan, Mr. and Mrs. H. W. Goddard, Mr. Charles W. Goodale, Mr. and Mrs. Henry Chester Greer, Mr. Abbot A. Hanks, Mr. and Mrs. Robert W. Hunt, Mr. Reiji Kanda, Mr. and Mrs. Clement Le Boutillier, Mr. and Mrs. William R. McIlvain, Mr. William McIlvain, Mr. and Mrs. Walter B. Manny, Mr. E. A. Montgomery, Mr. and Mrs. Willard S. Morse, Mr. W. V. Morse, Mr. and Mrs. Seeley W. Mudd, Mr. Seeley C. Mudd, Mr. Jose Muriel, Mr. and Mrs. T. H. Proske, Mr. and Mrs. Rossiter W. Raymond, Mr. and Mrs. Joseph W. Richards, Mr. William L. Saunders, Mr. and Mrs. F. C. Smink, Mr. Joseph Struthers, Mr. and Mrs. Edwin Thomas, Mr. A. E. Vaughan, Mr. and Mrs. Eli Whitney, Mr. and Mrs. William H. Wiley, Mr. and Mrs. David Williams, Mr. and Mrs. Newton R. Wilson, Mr. and Mrs. Philip Wiseman, Mr. P. Kenneth Wiseman, Mr. and Mrs. Otto C. Wolf.

Platinum Production in 1910

The production of crude platinum in the United States for 1910, according to Waldemar Lindgren was 390 troy ounces, having a value of $9507, the entire output being confined to placer mines in California and Oregon, where it is obtained in gold-washing. The production of California in 1910 was 337 oz. valued at $8386. This is chiefly recovered as a by-product of gold-dredging operations in Butte, Yuba, and Sacramento counties, though small quantities are derived from river gravels in Siskiyou and Trinity counties and from beach sands in Humboldt county. The production in Oregon is chiefly derived from beach sands near Port Orford in Curry county and near Bullards in Coos county. The copper mine at Rambler, Wyoming, is now finally closed down, having never been of importance as an actual producer. The production of crude platinum in the United States has been variable, ranging from over 1400 oz. in 1906 to 375 oz. in 1907. The production in 1909 was 638 oz. valued at $12,803. The price of ingot platinum has been equally variable, having been $20.50 per ounce in January 1906, increasing to $38 in January 1907, falling to $18.20 in August 1908, and having recently been quoted at $47.50 per ounce. Although prospecting for platinum has been carefully carried on in the United States, no deposits of much importance have ever been found. The world's supply of platinum is derived from Russia and Colombia, the former having produced 190,087 oz. in 1909, and the latter 6000 ounces.

Concentrates

Most of these are in reply to questions received by mail Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

MANGANESE is the best deoxidizing agent for nickel and its alloys. Not only does it remove the oxygen, but the sulphur as well.

TO REMOVE RUST from metal, cover the metal with sweet oil, rubbing it in well, let stand 48 hours. With a piece of cotton wool apply oil freely, then rub well with powdered unslaked lime.

PIPES used for conveying water to the electric power houses are often composed of California redwood. This is a great advantage, as such pipes cost less than metal ones, and are more durable.

COPRA is not a mineral, but is the dried meat of the cocoanut, and an important article of commerce in many parts of the Far East. Coprolites are the fossil droppings of sharks; neither of these substances contain any copper whatever.

POLYBASITE is a soft, iron-black silver mineral of the composition $(Ag,Cu)_9SbS_6$. It frequently occurs tabular crystals, and resembles tetrahedrite when massive. It can be distinguished by the reactions which it gives for lead before the blowpipe and when treated with acid.

TUNGSTEN is valuable as a filament in incandescent electric lamps because its melting point is very high, about 1700°C. It gives a whiter light than carbon, and is doubly as efficient. One pound of the metal is enough for thousands of filaments. Contrary to a generally accepted belief, tungsten is not used in the manufacture of armor plate, though it may have been used in experimental plates.

TOPOGRAPHIC atlas sheets of the United States are sold by the Director of the Geological Survey, at Washington, in accordance with an act of Congress, at the nominal rate of 5c. per copy—the cost of paper and printing—or $3 per hundred if at least 100 copies of any map or maps are purchased. They are also sold by dealers in many of the larger cities. The Geological Survey at Washington also publishes index maps showing the quadrangles which have been mapped throughout the United States, and a copy of this will be sent free to anyone requesting it.

NATURAL GAS can be liquefied by pressure, either alone or with the aid of refrigeration in a manner similar to that employed in the manufacture of 'blau gas,' which is liquefied under a pressure of 1500 lb. per square inch and is shipped in steel drums to wherever it is needed. On releasing the pressure the liquid becomes a gas again and can be employed for any purpose for which gas is used. Recently it has been claimed that gasoline may be made by compressing and cooling natural gas. While this is not impossible, it is not probable, and the claims should be carefully investigated.

DELAY ACTION fuses have been used to advantage in certain classes of adit or shaft excavation. These are made so that a very short space of time intervenes between their ignition by the electric current, and their detonation. Two kinds are manufactured, one kind detonates a little before the other, when both are connected in the same blasting circuit. When they are used in conjunction with regular electric fuses, the latter will detonate at the instant the electric current passes through the circuit; the first period fuses will follow, and the second period fuses will detonate a little later. By their use it is possible to fire one section of a blast sufficiently ahead of the following section for the material blasted by the charges in the first section to be blown out of the way before the following shots produce their effect.

WHEN a valve is wanted near a right angle turn in a pipe line, it is generally a good idea to use an angle valve instead of a globe or a gate valve, and an L, as it requires less joints to make and keep tight, and it makes a better looking job; also because less friction will be caused by water or steam passing through the line. On pipe lines that are to convey superheated steam from one point to another, it is not wise to use valves with hard rubber disks in them, as the heat will dissolve them in a short time. Use only brass or gun metal valves for such places, or remove the hard rubber disks and substitute one made of bronze.

MINE FIRES often burn for long periods of time. Probably the best known mine fire in the United States is that near Summit Hill, Pennsylvania, on the property of the Lehigh Coal & Navigation Co. The fire in question was discovered February 15, 1859, and has been burning continuously ever since in spite of several efforts to extinguish it. It began and has continued in the mammoth vein which, through this section, is about 50 ft. thick, and as in the early workings of this vein the coal was very imperfectly taken out, a large amount was left for the fire to feed upon. It is also close to the surface and the rocks overlying the coal have caved and been broken in many places, affording ample inlet for air and making it very difficult to seal off the fire by closing up old passage ways. Various schemes for checking the fire have been tried, but thus far have not proved effective. The distance from the point of origin of the fire to its present location is now about 4000 ft. and the burned out area varies from 600 to 1500 ft. in width. Should the fire advance much farther, it would pass over the anticline and into the Lansford Valley in which the area of coal exposed to attack would be greatly increased. It was, therefore, decided to attempt to seal off the fire by clay barrier entirely across the coal seam and preliminary work was begun December 18, 1908. The work is still in progress and it is estimated that 100,000 cu. yd. of clay will be needed to fill the shafts and to construct the barrier.

THE APEX LAW or right to follow the vein indefinitely on its dip, was originated and put into practice by the miner, who believed that the discoverer of a vein on the surface, was entitled to all of the vein in depth as his reward; also, that if the right to follow the vein in depth was not granted him, he would of necessity have to appropriate a large amount of ground on each side of the outcrop or apex of the vein, in order to insure his possession of the vein in depth, which would work a hardship on him in trying to hold the ground and on others in preventing them from prospecting this additional area. At the time the law was originated, the 'true-fissure' type of quartz vein was the prominent and ruling type of orebody known. Such a vein occupies a fairly regular fissure in the earth, and is comparatively clear cut and well defined. It may be likened to a leaf within a book. If all veins or lodes were of this type, the wisdom of the epex law would be unquestioned. As mining progressed, it was found that ore deposits departed more and more from the theoretical idea of a vein or lode upon which the law was founded, especially in the case of base-metal vein and lodes, and impregnation and replacement deposits. The questions that arose regarding the apex law were of two classes. The first question was, who had the apex according to the geologic facts? The statutes, it was soon evident, had made no provision for the varying conditions under which apexes and claim-lines were found. Having determined the geologic facts as to who had the apex, what decision should be handed down, became the second question. The second question, one of law, has been answered by the various court decisions covering most of the forms of apex and claim-line occurrence, so that if the facts of the apex are established, the law can be applied. The first question, what are the conditions under which the vein or lode occurs and who has the apex, the question of fact, can only be determined by geologic investigation and engineering work, and is the difficult point in all apex suits.

Special Correspondence

ST. PETERSBURG, RUSSIA

Russian Gold Production. — Total Production by Dredging.—Yield per Dredge.—The Most Successful Dredges.

The 1910 results of the gold and platinum production in Russia and Siberia by means of dredging show a large increase over 1909, and furnish additional proof of the importance of dredging in the Russian and Siberian gold and platinum fields. The number of dredges in the goldfields continues to grow and is now stated to be 66, compared with 55 in 1909. The increase is accounted for by the installation of new dredges by the Nishni-Tagil and the Amgun company, besides the setting to work again of some old dredges. But although 66 dredges are at work, returns are available only for 55; the owners of the remaining 11 having for one reason or another abstained from making the statement of their year's work as requested of them. The number of working hours done per dredge (average) was the largest of the five years of which 1910 was the last; though the quantity of sand washed per dredge was slightly inferior to that washed in 1909, but greatly superior to the next preceding years; and again the quantity of gold produced was slightly inferior per dredge to the corresponding result of 1909. For the purpose of comparison the metallic gold return per dredge is given for the five years ended 1910, thus: 1906, 2 poods,* 22 funts, 24 zolotniks; 1907, 2p. 6f. 67z.; 1908, 2p. 28f. 91z.; 1909, 3p. 17f. 54z.; and 1910, 3p. 16f. 10z. This close resemblance in the returns for the last two years suggests that little advance had been made in that period either as to improvement in the technique of the industry, or as to the selection of ground on which to work. That is, that higher grade sands than those hitherto worked have not yet been found.

Although the yield of gold per dredge was smaller than for the preceding year, the total result is a substantial advance because of the larger number of dredges engaged in the work. The increase over 1909 amounts to 25 poods, 32 funts, or 183p. 15f., against 157p. 23f. The increase is sufficiently large to prompt the observation that dredging is a continuously growing element in the Russian gold and platinum industry, with the reserve that notwithstanding the increased extent of the Siberian gold sands offering such an ideal field for the use of dredges, these do not require such a relative importance as they have acquired in other countries. The increase is due to the installation of new dredges; probably of large bucket capacity and improved workmanship. No doubt is entertained that the use of dredges on these great and suitable goldfields will continue to advance. One of the most powerful causes of the dilatoriness in that application is the cost of foreign dredges under the protective tariff to which must be added the confessedly inferior quality of the Russian built dredge. The attitude of the Siberian goldfield exploiters toward this question is one of unending protest against the disabilities under which the gold industry must labor as long as foreign dredges are so dear, and home dredges are so poor. An idea is given of the capacity of the dredges by a table showing their production, thus: eight dredges produced less than 1 pood; one produced between 1 pood and 1 pood 20 funts; five between 1p. 20f. and 2p.; nine between 2p. and 2p. 20f.; eight between 2p. 20f. and 3p.; six between 3p. and 3p. 20f.; four between 3p. 20f. and 4p.; four between 4p. and 4p. 20f.; two between 4p. 20f. and 5p.; two between 5p. and 5p. 20f.; and one each between 5p. 20f. and 6p., 6. and 6p. 20f., and between 6p. 20f. and 7p. To these 52 dredges there remain to be added three which produced 8p. 36f., 10p. 32f., and 16p. 5f. respectively. These three remarkably successful dredges operated on the Demidoff San Donato Successors' works in the Nishni-Tagil area; and as they are all in the same ground, it may be assumed that their success is due rather to the richness of the sand than to the superior efficiency of mechanism.

The next most successful dredge was that of the Southern Taiga, belonging to the Fedoroff Gold Co. Its production was 6 poods 27 funts. This company had also a dredge each on the Southern and Northern Taiga respectively, which yielded over 4 poods each. It had nine dredges at work. The Trans-Ural Mining Co. operated a dredge on the Solvin goldfield which won within a fraction of 6 poods of gold and platinum. The Neviansk company produced 5 poods 6 funts of gold and platinum by one dredge. This company had seven dredges working. It has quite abandoned dredge building, to which branch of industry it paid much attention in time past. No other dredge on the Russian Siberian fields reached the 5 poods level, though numbers reached 4 poods and upward. A number did not even reach 1 pood.

JOHANNESBURG, TRANSVAAL

Records of Production for August.—Missing Gold at East Rand Proprietary. — Proposed Increase in Equipment.—The Miners' Phthisis Problem.

Again the Transvaal monthly production of gold exceeded three millions sterling in value, the Chamber of Mines' declaration of the output for August being 713,407 oz., valued at £3,030,360. Of this yield the Rand alone was responsible for 682,401 oz., valued at £2,989,673, and it is not too much to expect that by the end of the year the Witwatersrand alone wil declare an output of three millions sterling. But for the strange affair in connection with the East Rand Proprietary Mines, which to the man in the street remains as much an enigma as ever, the three leading companies would have again produced quite a fourth of the total output of the Rand. The Crown Mines again did well, crushing with its 640 stamps and 19 tube-mills 149,000 tons, yielding 59,464 oz. valued at £252,587; but these mines are destined to do even better in the future when the new mill gets fairly at work. Randfontein also did well with its 750 stamps and 23 tube-mills crushing 198,252 tons, yielding 57,334 oz., valued at £243,539, and the coming race between these two companies for the position of premier gold producer of the world, promises to be a very interesting one. It is pleasing to be able to report that despite the somewhat general scarcity of unskilled labor, the Randfontein property has been able to increase its ore reserve, during the last half year, by well over half a million tons; that is, from 6,289,300 tons to 6,870,200 tons. Considering that over a million tons was crushed during the same period, and that for such a huge milling equipment as that existing at Randfontein, the ore reserve at the starting of the big mill was somewhat small, the achievement is therefore all the more welcome, as it places the property at once in a sound position. The East Rand Proprietary Mines have again sunk to the third position on the list, and it would almost seem that they are destined to occupy that position for a considerable time to come.

Further official and semi-official statements have been issued during the week, but they throw little additional light on the actual cause of the disappearance of the 13,000 oz. of gold at the East Rand Proprietary. The greatest loss hitherto known on the Rand through zinc-shaving failing to precipitate the gold is recorded as 500 oz., and how a loss of 13,000 oz. could arise without some gross neglect has yet to be explained in face of the high standard of metallurgical talent hitherto always at the disposition of the East Rand Proprietary Mines. W. A. Caldecott, who has had considerable experience and is justly regarded as the leading metallurgical expert on the Rand, gives it as his opinion, after an exhaustive investigation, that the 13,000 oz. of gold will probably be lost, while the mining editor of the *Star*, in what is apparently a semi-official statement, says that there may be some grounds for hoping that some of the missing gold may yet be recovered. Naturally most credence is attached to Mr. Caldecott's opinion, the hopes expressed that some of the gold may be recovered only tending to add to the existing confusion. In another statement of the position having all the appearance of coming from an inspired source, it is stated that the trouble dates back to the days of dual management. As the days of dual management came to an end about twelve months ago, this statement also tends to add to the confusion rather than otherwise, because surely a twelve months' period ought to be sufficient time to allow things to be put right, whereas they would appear to have gone from bad to worse. It is during the last twelve months that most of the trouble has arisen at the East Rand Proprietary Mines culminating, however, in the present impossible position. Retrenchments, fire, and accidents have all occurred during the last twelve months, and left their mark upon the company's history and profits. A hesitating, changing policy has also been pursued, followed by the closing down of a portion of the deepest section of the property, when the best interests of the company would seem to indicate the necessity of driving to the dip to ascertain the facts. The Micawber-like policy pursued with regard to the missing gold has not given satisfaction to the shareholders, nor have the labored efforts made to show that the mine is all right. Had the shareholders been advised promptly that the gold was not being recovered as anticipated, it is probable that the shares would not have depreciated to the tune of over two millions sterling, and the desperate steps taken to hide the troubles would never have been necessary. However, the proposal to establish a cash reserve fund with the object of equalizing dividends is certainly a step in the right direction, as is also Mr. Caldecott's proposal to add to the reduction equipment; but in the face of recent disclosures and what is known about the property, it may be deemed necessary to add to the equipment even to a larger extent than recommended so as to work the mines on a more extensive scale. Under the circumstances, the anxiety felt by the shareholders should be considerably allayed by the announcement that Sir Geo. Farrar, chairman of the company, sails from London in a few days' time with the object of reorganizing affairs at the mine.

---

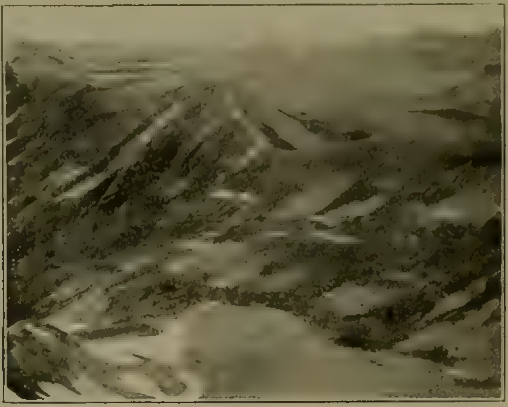
*1 pood of pure gold = $10.886; 1 funt = $272.17; 1 zolotnik = $2.835.

A topic of some interest on these fields is just now that of miners' phthisis, recent investigations showing that it is undoubtedly on the increase. A mining engineer who was formerly Commissioner of Mines, now a prominent member of the Labor party and Government Commissions, suggests as a remedy the abolition of contract work on the mines as a cure for the disease. This suggestion has the merit of novelty, however impracticable it may be, and coming from an ex-member of the Transvaal Legislative Assembly and some time principal member of the Mines Department under the Crown Colony Administration of Lord Milner, may seem to call for some comment. The suggestion to abolish contract labor underground seems to admit that the miners place more importance upon earning high wages than on the preservation of their health. There can be no doubt about this, because no matter what facilities the mine-owners may provide, in accordance with the mining regulations, to prevent the formation of dust underground, the miners steadfastly refuse to use them. It does, perhaps, seem strange that a government will go to all the trouble of passing the legislation necessary for the protection of the health of the miners, and even appoint a staff of mine inspectors to administer the law, without insisting that the laws shall be obeyed. The refusal of the miners to observe the mining regulations also seems strange when their observance would not only protect their health against miners' phthisis, but would also help them in the work, as shown by a paper read before the local Institute of Engineers by one of the inspectors of mines. The administration of the mining regulations has been somewhat difficult in the past and remains so today by the lack of the needed co-operation prevailing almost throughout these fields between the miners, mine officials, and Government inspectors, to insure the due observance of the regulations. That with such co-operation the mining regulations can be carried out on this question without entailing any loss to the miner was clearly shown in the above-mentioned paper. The number of miners suffering from phthisis on the Rand is variously estimated to range from 20 to 25%, of those employed, and even if the application of water might result in a little inconvenience to the miner when drilling, the preservation of his health ought to be of the first importance. Government inspectors, as a rule, do not show much hesitancy in insisting on the full observance of the mining regulations, and why they should do so in this instance is difficult to understand, especially seeing that at the Nourse Mines the management has succeeded by sheer force and determination in carrying out the dust-prevention clauses of the mining regulations.

SILVERTON, COLORADO

Disastrous Flood in San Juan County.—Vermillion Closes. Iowa Tiger Reduces Force.—Aspen and Nevada Resume.—Silver Ledge Flooded.

A heavy rainstorm, lasting nearly 24 hours, resulted in one of the most disastrous floods in the history of the San Juan on October 4. Telegraphic and telephonic communication with Durango were cut off and details of the disaster are just coming in. The mines escaped serious injury, but the railroads were badly damaged. The line from Silverton to Animas Forks is in fair shape and will be repaired at once. The Gladstone road is badly damaged and it is doubtful if it will be reconstructed this fall. The Mineral creek road, joining Silverton and Red Mountain, suffered severely, but will be repaired at once, as the greater part of the food supply must come that way until the main line of the D. & R. G. can be restored. On this line the greatest damage was done. The track from Silverton to Needleton is in good shape except for several small washouts, but from Needleton to Tacoma, a distance of about 15 miles, the track is all gone and the river has washed the canyon clean from wall to wall. It is variously estimated that it will require from one to two months to repair this line.



A GLACIAL CIRQUE NEAR SILVERTON.

The Vermillion mine at Animas Forks has closed down because of insufficient funds to meet the payroll and other obligations. This mine has been employing an average of 70 men. The Sound Democrat is working three shifts in the mill and crushing 25 tons per day. No shipments have yet been made so that the results under the new lease are not available. The Iowa Tiger Leasing Co. has reduced its mine force, as the new bodies failed to extend more than 30 ft. above the fourth level, although the third level was in good ore above. Development work will be started on the Tiger side in the near future. The Silver Lake has 40 men at the mine and is milling about 50 tons per day. The ore is of better grade than last month. The Aspen is being cleaned out and retimbered and some development work will be done. The Nevada, part of the estate of the

Silver Lake, has been leased to Walter Eals, formerly mine foreman at the Silver Lake, and the lessee is prospecting in the hope of finding some shipping ore. The Gold King is subleasing and expects to mill about 150 tons per day. The lessees will do no mining, but will depend upon their sub-lessees for ore, and operate the tram and mine. The Hercules flume was wrecked by the flood and will require several weeks work to repair it and again operate. The Silver Ledge filled with water from the sixth level to a point about 40 ft. above No. 5 level. All pumps are drowned and the company is bailing water. The Congress is shut down because of a burnt-out transformer. This will be repaired at once and development resumed on the excellent ore developed on the surface during the last month.

Future operations in this district depend very much upon the speed with which the railroad is opened and the storage capacity of the mills. Should there be no train to Durango for 60 days most of the plants of this county will be stopped. There is an ample coal supply on hand, but a poor supply of food stuff. Provisions are already being packed from Ouray, and so long as this road is open there is no danger of a shortage.

NEW YORK

ABANDONMENT OF COPPER MERGER.—COPPER SITUATION.—MARKET PECULIARITIES.—RECONSTRUCTION OF ARIZONA COMMERCIAL SMELTER.—SHATTUCK-ARIZONA DEVELOPMENT.

The important event of the week in mining circles was the final open abandonment of the proposed Calumet & Hecla merger. The directors of the Calumet & Hecla Mining Co. have given out a statement which goes no further than to say that owing to the delay caused by litigation, it is thought best to abandon all plans for consolidation, and the proxies of the Calumet & Hecla company will be voted against the merger at the meeting to be held at Laurium, Michigan, November 16. There are several factors which have undoubtedly influenced the directors in fixing their present determination. The uncompromising stand taken by the Federal authorities on all questions arising under the Sherman Anti-Trust Act has greatly retarded the development of all merger plans, and, in spite of the several announcements to the effect that all of the suits brought to enjoin the Calumet & Hecla merger would be fought to final decisions, the likelihood that the new enlarged Calumet & Hecla would be born an outlaw, was probably the ruling consideration. Copper merger talk has, of course, been without foundation for some months, and, in view of the Calumet & Hecla action, may now be finally dismissed, until the present situation shall have been settled in some reasonably permanent manner. As the proposed plans go into permanent pigeonholes, it may be anticipated that the discussions which have been raised as to the values of the subsidiary companies will be quieted. The Ahmeek, the absorption of which was most bitterly contested, is to make early entry into the ranks of the dividend payers, with an initial distribution of $2 per share. One thing which is gained by the old Calumet & Hecla is an increase of its copper-selling business. Several of the Lake properties which were to have been absorbed formerly sold their copper through the United Metals Selling Co. Hereafter the copper of the Ahmeek, Osceola, Tamarack, and Isle Royale will be marketed by the Calumet & Hecla. The aggregate output of these companies is some 56,000,000 lb. annually, but Michigan deep-level mines are in many cases biding their time and awaiting a betterment of the metal market. The contracts which the Calumet & Hecla have secured are therefore a good asset for the future and will be of increasing assistance in maintaining a steady level for Lake copper.

Copper producers in general appear to be tightening belts and preparing for a further indefinite period of low prices and decreased consumption. Unsettled conditions abroad must cut down the real export demand, and, while it is said on all sides that stockyards are as bare as they can be so long as business continues at all, yet there is no incentive, either in general business conditions or in the copper situation itself, to induce consumers to take on copper. The increase in surplus of some 7,500,000 lb. was not treated as of any particular importance. Exports were off as expected, domestic consumption exceeding the export figure for the first time since May last. The important element in the copper situation for the near future is the new production, and the analysis of the cost-sheets of the new mines will determine largely its weight as a controlling factor. Is the present copper status due to the development of metallurgical processes and automatic machinery capable of handling immense tonnages rather than to any actually overabundant supply of copper? Will the enormous investments made in the steam-shovel properties force continual production at capacity and drive the metal to lower prices? Will many of the principal deep-level mines be forced to restrict production or close down altogether until nearing exhaustion increases costs for the porphyries? As an example of modern commercial development, as a concrete economic problem, and as an illustration of the present world-wide organization of business, the copper situation is peculiarly interesting. It appears to present one of the strongest arguments in favor of combination against competition in the interest of conservation, and might well be pointed out by those who are trying to combat the overpowering sentiment of the day against all forms of large combination.

Some of the market developments of the week have been aptly illustrative of the absence of public interest. Tuolumne failed to declare its regular quarterly dividend, since which announcement the shares have been advanced and the market held apparently strong, mostly because there was no attempt by the public to make market capital out of the cessation of dividends. Another instance was the advance in Chino and in Ray Consolidated immediately upon the appearance of the monthly figures of the Producers' Association. In neither case was market action logical, nor would it in either case have been possible with a public in the market. Live Oak Development, one of the important properties at Miami, is to be traded in hereafter on the Boston Exchange. The brokers in the Boston market are gratified over the abandonment of the Calumet & Hecla merger.

The plans for the reconstruction of the plant of the Arizona Copper Co. are moving along without hitch. Some months ago, a number of the officers of the Arizona came over from Edinburgh and in company with L. D. Ricketts of the Greene-Cananea made a tour of inspection, with a view to choosing a site for a new smelter. Mr. Ricketts' report on the general condition of the property has been sent to Scotland, and it is expected that all decisions will be made and actual work begun without loss of time. The $2,000,000 which will be expended for a new equipment under Mr. Ricketts' supervision will be raised abroad. Mr. Ricketts' work on the Greene-Cananea and his present task for the Scotchmen in control of the Arizona entitles him to a leading place among the engineers engaged in construction of reduction plants. On the Greene-Cananea, the old plant was almost past rebuilding, but is now a model of up-to-date completeness. The Arizona equipment has for many years been considered remarkable, inasmuch as it held together and managed to pay a profit. Not until the death of the late John Gill of Edinburgh, for many years chairman of the board, was it possible for the more progressive directors to obtain consideration for plans to rebuild the antiquated plant, now to be replaced by a new one rather than reconstructed.

Chino has the first unit of its concentrator in commission. The other units are expected to start up at intervals of thirty days, and the whole plant will be in operation before midsummer of 1912. Chino will probably be one of the important producers from porphyry ores, as it will be mined for the greater part by steam-shovel work. Shattuck-Arizona, which recently met the copper situation squarely by suspending shipments, is to build a smelting plant of two blast-furnaces and a converting plant. Some $450,000 will be expended in construction work which will be in charge of J. E. McAllister, general manager for the British Columbia Copper Co., Greenwood, B. C., and who will later act as general manager of the mine and smelter. The Shattuck is an example of individual conservation of resources. The mine can make money on the present metal market, but the management has insisted on developing the mine, and in doing so is removing as little copper as possible.

It is something of an innovation for new copper producers to place selling contracts in the hands of individuals, when so large a percentage of the business has been handled for such a length of time by the United Metals Selling Co. and the American Smelting & Refining Co. S. S. Rosenstamm, who was for some years with the old United Metals Selling Co. before it was connected with the Amalgamated Copper Co. and while it was still controlled by the Lewisohn Brothers, has secured a contract to handle the copper of the Miami Copper Co. This year is not expected to see Miami producing at capacity, but Mr. Rosenstamm will have the marketing of probably 30,000,000 lb. of copper during 1912.

The Bonanza Development Co. of Colorado, which at one time owned the Santa Rita ground, which it sold to the Chino, has declared a dividend of 20c. per share. The last dividend paid in June 1899, was $1.50 per share, and was paid out of the proceeds of the sale of the Chino. The Bonanza Development Co. was organized in 1880 with a capital of $300,000. Out of its operations and sale of properties the stockholders have received $1,425,000.

The advantage of large acreage at Cobalt is illustrated by the action of the Kerr Lake Co., which has been compelled to again reduce its quarterly distribution, having now discontinued all extra payments and retaining only the regular dividend of 25c. per share. Kerr Lake has made a splendid record; the mine made some of the cheapest silver produced in Cobalt, and the shareholders have had some three and three-quarter millions in dividends. Like Goldfield Consolidated, Kerr Lake paid 50c. per share and sold on a basis where it returned better than 30%. Were the property of larger extent, like La Rose and Nipissing, its position would be much stronger. The company holds a large interest in the Wettlaufer in South Lorrain, a producing property, but this interest of 150,000 shares outstanding can hardly be expected to reinstate Kerr Lake as a spectacular dividend payer.

TORONTO, CANADA

Change of Government.—Possible Coal Famine.—Reconstruction at the Dome.—Mill Construction at the Vipond.—Progress Notes.

The accession of a Conservative government at Ottawa has involved some changes in mining administration. It is a little too early as yet to forecast any changes in policy consequent upon the political overturn, but the mining interests are hoping for more vigorous and energetic action in regard to several important questions affecting the industry that has been displayed in the past, and more particularly for the speedy enactment of a uniform mining code and an effective measure regarding the storage and handling of explosives.

Owing to the protracted strike of coal miners in British Columbia, serious fears have been for some time entertained of a coal famine during the winter in Saskatchewan. Some weeks since, the Government temporarily removed the duty on coal imported for western consumption, as a precautionary measure, and the Saskatchewan government issued strong appeals urging all who could afford to do so to lay in their supplies as soon as possible. The question was energetically taken up by civic and public bodies, and for some time large shipments from the American mines have been going forward. It is hoped that by the close of navigation sufficient supplies will have been laid in to provide for the needs of the settlers through the winter, though even in that case, there may be considerable suffering in the more isolated districts. In addition to the heavy importations required to meet the normal demand of the prairie provinces, the great railroad companies have been importing and storing unusually large quantities for their own use. As a general rule, they only lay in during the fall sufficient fuel to last them until the opening of navigation. This season, however, they are accumulating a supply which will provide for at least a year's consumption ahead. It is stated that they anticipate a protracted strike of the American miners next spring, when the termination of the agreement now existing between the miners and the operators will probably be the occasion of a demand for a large increase in wages.

Construction work on the Dome is employing a large force of men, the permanent buildings being nearly finished. The scale on which they are built is indicated by the fact that about 1,000,000 lb. of steel was required for the work. The extensive buildings of the Dome Extension are also nearing completion. Both companies have well equipped, independent power-plants, so that in case of the failure of a supply from outside, there need be no suspension on account of lack of power. Diamond-drills are working on the vein known as the Golden Sidewalk on both the Dome and Dome Extension, and it is stated that at 500 ft. on the former property the vein shows equally as rich as on the surface. Work has been resumed on the main shaft of the Dome Extension. At the Pearl Lake the encouraging results from core-drilling have decided the management to put down the main shaft to 400 ft. No cross-cutting will be undertaken until this level is reached. The Vipond has raised sufficient funds by the sale of treasury stock to provide for the erection of a mill of 100 tons capacity, and construction will begin at once. At the Rea a large body of ore has been blocked out. The main shaft is being continued to 300 ft. Shaft No. 2 is down to the 200-ft. level and is connected by an adit with the main shaft. The principal vein has been uncovered for over 400 ft. and is from 12 to 20 ft. wide. Harold Kingsmill, lately in charge, has resigned in order to accept a lucrative appointment in South America. The Crown Chartered is developing the Davidson claims, adjacent to their original holdings. A shaft is down 73 ft. on the lot known as Davidson No. 1. It will be put down to 110 ft. and a cross-cut run to find the vein. The McIntyre has decided upon a 40-stamp mill, which is being designed by A. G. Kirby of New York. It is expected that three of the shafts now going down on this property will reach the 200-ft. level in two weeks, when development will be carried on with 12 drills in operation. The Eldorado has found good ore at the bottom of a 30-ft. shaft. A Nissen drill is being set up on the property of the Niagara Porcupine company in Deloro. A 6-drill compressor has been installed on the Apex. The Porcupine Reserve is opening up the Birke claim, about a mile southeast of the Hollinger. A surface lead has been discovered which pans free gold, and a shaft is being sunk. After uncovering a vein 4 ft. wide and showing free gold for 130 ft., operations on the Success, owned by English capitalists, have been discontinued. The Scottish Ontario, hitherto operated by a syndicate, has passed into the hands of an English company, which will be represented in Canada by John Willocks. It is capitalized at $1,000,000, but the stock will not be placed on the market.

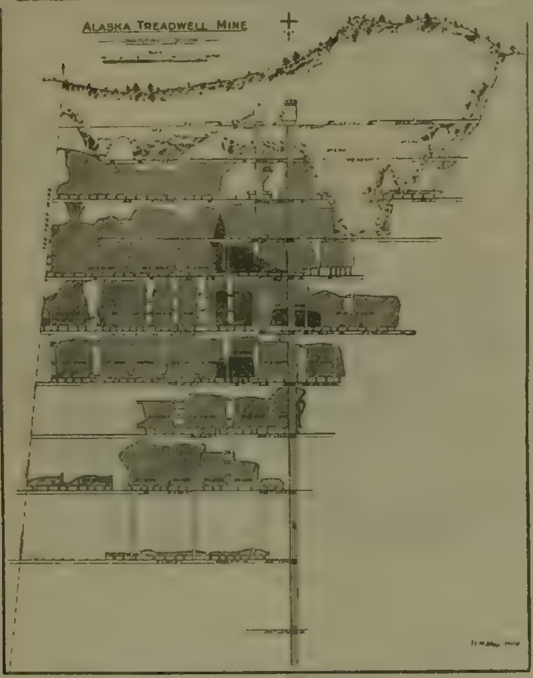
TRAIL TO PORCUPINE IN WINTER.

General Mining News

ALASKA

JUNEAU

The Alaska Treadwell G. M. Co., in the month ended September 15, made a net operating profit of $113,078, from a total of 79,380 tons of ore crushed. The sulphides saved amounted to 1571 tons. The gross value of free gold for the month is estimated at $117,808, according to the official report, and the sulphides at $93,531, making a total production of $211,340, with a realizable value of $205,626. Operating expenses amounted to $92,548. The yield per ton of ore milled was $2.66, and the stock of broken ore was increased by 22,931 tons. Construction expenses amounted to $18,338. During the month, 1119 ft. of development work was done.



LONGITUDINAL SECTION, ALASKA TREADWELL MINE.

PRINCE WILLIAM SOUND

The report of the Sealey-Davis M. Co. for the year ended September 30 includes the following items: Total receipts, $25,289, of which $25,000 was from the sale of stock; cash on hand, $1935; improvements, $2228; expense (surveying, attorney's fees, and office), $1678; development, $15,748. The annual meeting of the stockholders was held October 3 at Valdez. During the year 1246 ft. of adit was driven at an average cost of $10.44 per foot, with an average cost of $1.04 per foot for mine supplies. The company has 12 claims surveyed.

A large shoot of good-grade ore has been found in the Willow Creek district on the property of the Gold Bullion M. Co. In a three days' run, with seven stamps dropping, according to reports from Valdez, about $5000 in gold was extracted. The mill is handicapped by lack of power, but the companies operating in the district are planning to unite in the construction of a large electric plant. William Bartholf is superintendent for the Gold Bullion company.

Sam Erickson has discovered exceptionally rich ore near Chitina. It is believed that the vein is the source of the rich float found in O'Brien creek.

The Standard Mines Co., capitalized at $1,000,000, has been organized at Cordova, to prospect in that district. R. J. Barry heads the board of directors.

The Skagway Milling Co. has been formed with a capitalization of $10,000. L. S. Keller heads the board of directors, according to recent reports from Cordova.

THE TANANA

Reports brought to Fairbanks by the steamer *Reliance* are to the effect that ore panning $40 to $50 per pan has been discovered along the Hammond river in land which has been prospected many times without finding the paystreak. The dredge of the Alaska Exploration Co., known as the English syndicate, reconstructed on Fairbanks creek, was put in operation September 11.

ARIZONA

GILA COUNTY

Shaft No. 2 of the Live Oak company is down 830 ft. and is still in the comparatively high-grade ore found at 705 ft. It is reported that the ore pierced by this shaft so far assays on an average over 3% copper. Five churn-drills are being operated and two holes are in ore.

The experimental mill at the Inspiration mine is being enlarged to a capacity of 150 tons per day for trying out the concentrating method proposed by J. M. Callow. In preparation for active development, the track in the main adit is being widened to a 30-in. gauge. It is estimated that about 4,500,000 tons of ore can be extracted through this adit, and that the rest of the ore must be taken out through shafts. Surveys are being made for pumping stations, reservoirs, and pipe-lines.

The Miami company, with its four sections of the mill in operation, is mining and milling about 1850 tons of ore per day, and is producing about 82 tons of concentrate averaging from 41 to 42% copper. The mill recovery is about 70 per cent.

CALIFORNIA

INYO COUNTY

(Special Correspondence.)—The Four Metals Co., operating the Cerro Gordo mine, near Darwin, is shipping 40 to 50 tons of $50 silver-lead ore per week. Shipments are made to the United States smelter at Salt Lake by way of Mina. This ore is coming from between the 600 and 800-ft. levels. L. D. Gordon and associates, who have a lease on the zinc producing veins of the property, are shipping about 30 tons of zinc ore per day to Oklahoma. The ore is from the Union adit, 200 and 400-ft. levels. The zinc carried by the product averages 35%. Eastern people have taken a bond on the Unexpected, in the Pine mountains, a few miles from Big Pine. The bond is for $10,000 and a one-third interest. Work is to start within two months, and the payments to be made in three installments, at the end of four, eight, and twelve months, respectively. The vein consists of altered rhyolite lying between gray porphyry and lime shale, and is said to be over 35 ft. wide at surface, and to be traceable for two miles. The claims were located three years ago by Wilkinson brothers, of Big Pine.

Bishop, October 13.

KERN COUNTY

(Special Correspondence.)—On the Royal Bohee group of claims near Randsburg, five veins of tungsten ore have recently been discovered. It is reported that in trenching the veins, 6 tons of ore averaging 8% tungsten has been sacked. On another part of the claims four tons of $40 gold ore has been taken out at the surface.

Randsburg, October 16.

NEVADA COUNTY

Joseph N. White and William A. Worthington, miners engaged in retimbering the shaft of the Champion mine, were killed on October 10 when John Hooper, hoisting engineer, let a car he was oiling start down the steep inclined shaft without being attached to the cable. Hooper has been engineer at the Champion for ten years.

SIERRA COUNTY

(Special Correspondence.)—The Tightner mill went into commission today and is working satisfactorily. The plant comprises 10 stamps, and it is planned to operate all winter, an abundance of ore being available. Eight sacks of high-grade ore, valued at about $20,000, were shipped to San Francisco last week from the Twenty One mine. This property adjoins the Tightner and is operated by San Francisco people. The vein is reported to be about 18 in. wide and has been opened at a point 500 ft. below the Tightner lower workings. F. M. Phelps is manager. It is reported that work has been resumed at the Poker Flat gravel property. M. Duvall is manager. At the Ante Up, near Mountain House, a 4-ft. vein has been opened. Samples of the quartz are said to run about $40 per ton. A drift is being extended along the vein which is showing excellent strength. Horace A. Morse is superintendent. The Neocene M. Co. is enlarging its restraining dams and otherwise arranging for larger operations. Pipes have been laid to work the deposits under the old town of Scales Diggings. This is one of the largest active hydraulic properties in central California. J. F. Johnston is manager. Good gravel has been opened on the Taft-Sherman property, in Jim Crow canyon. Considerable coarse gold is reported. The gold is recovered by sluicing. J. B. Carney is in charge. A chimney of high-grade quartz was recently discovered at the Osceola, situated between the Tightner and Nonpareil mines. The main vein is 6 ft. wide with milling value prevailing throughout. The property was recently reopened after lying idle for 20 years. Dan McGonigal is manager. C. M. Root, manager of the Gladstone mine, near Gibsonville, announces plans to add more stamps to the mill. A recent run showed the quartz plating $22.50 per ton.

Alleghany, October 14.

Trinity County

Work is progressing rapidly on the Alta Bert dredge holding, sometimes known as the Payne ranch, at Trinity Center, say recent newspaper reports. The property has been bonded to San Francisco men, who have purchased the Callahan dredge, a 7-ft. bucket-type outfit, built about three years ago for the Callahan ranch in Siskiyou county. The dredge, with electric-light plant, cost about $168,000, but was offered for sale last year for $75,000. The McDonnell placer mine, the Larsen tract of 30 acres, and the Ellery claims of about 50 acres, have been bonded to the same people.

Tuolumne County

(Special Correspondence.)—The price to be paid for the Longfellow group of mines by Sol Kahn, of San Francisco, became known this week through the recording of the bond, which calls for the payment of $100,000 in installments before November 1, 1916, as follows: First payment of $7500 in 8 months; $10,000 in 20 months; four payments of $10,000 each, 6 months apart; $12,500 in 56 months, and $12,500 in 62 months. Absolute title to the entire property will be given for $75,000 if payment of that sum be made before the expiration of 20 months. Mr. Kahn agrees to operate the mine continuously, expending at least $2000 each month in the development of the property, and is to pay to the owners 50% of the net returns, which will apply on the purchase price.

Los Angeles and San Francisco investors are to begin development in the Big Four mine, near the old Dead Horse mine. The property is owned by W. D. Deming, of Tuolumne. A long adit exposes a strong vein of milling ore. Rich ore has been found in the Somerset mine, which, with the Spring Gulch property, is being operated by W. B. McCubbin and George Ash. The find was made at a depth of 100 ft., the vein from side to side being 5 ft., all milling ore, with a streak several inches across that will run as high as $1000 per ton. The Somerset is owned by the William Sharwood estate, but it is understood that the bondholders will soon make the payment that will give them absolute title to the property. Hoisting has been done by means of a whip, but it is announced that an up-to-date equipment for the development of the property will be put in.

Tuolumne, October 14.

(Special Correspondence). In the Black Oak mine, the management reports, the north drift on the fifteenth level (1300 ft. deep) is now out 575 ft. following the body of ore found in the cross-cut on this level. This drift shows a 4-ft. vein of ore assaying about $22.50 per ton for the entire length, with 5 ft. of good ore in the face. On the fourteenth level, 120 ft. above the fifteenth level, the drift is out from the fault 150 ft., showing the orebody to be the same size and value on this level. A raise from the fifteenth level to the fourteenth level, has just been completed in the ore, giving good ventilation in this part of the mine. The property is equipped with a mill and cyanide plant, in which some changes are contemplated to bring its capacity up to 100 tons per day. The property is controlled by Charles E. Knox, John Bryant, and S. A. Knapp, of San Francisco. R. C. Knox is superintendent.

Tuolumne, October 16.

COLORADO

To give the mine operators of the State a better acquaintance with the latest mining methods, the Colorado Scientific Society has appointed a committee to arrange a series of practical lectures or talks. The members of the committee are R. A. Parker, a mining engineer of recognized ability, and Victor C. Alderson, president of the Colorado School of Mines. Fifteen or twenty speakers will be secured, and the course probably will be given at Silverton, Ouray, Idaho Springs, Boulder, and other mining towns.

Clear Creek County

Ore from the Ready Cash vein near Williams Forks, owned by John C. DeVotie, milled 259 oz. silver and 19% lead, say reports from Georgetown, and there is a good vein. Mr. DeVotie, however, stated that life is too short to spend it in such a desolate country. He recently inspected the property worked by Bert Hagar, two miles from the Ready Cash mine, and is of the opinion that later on when the Hagar property is developed by men with capital it will be a big mine.

Dolores County

The discovery of a body of copper sulphide ore entirely free from zinc on a new claim known as the New Year is reported by the owner, M. T. Chestnut. The claim is situated near the Rico townsite on Newman Hill, and the ore is the first copper sulphide opened in this part of the district. It will average, it is said, 15% copper, 30 oz. in silver, $5 in gold, and 10% lead, and some of it runs as high as 40% copper and 100 oz. in silver.

Leadville and Mexico operators, according to newspaper reports, have secured an option on the A. B. C. group in this district from John W. Burns and E. A. Thayer. The price reported is $75,000, and payments of $10,000 per month are to be made beginning October 1.

Ouray County

Thomas B. Crawford of Denver has secured an option on what is known as the old Hill smelter at Ouray. If successful in financing the enterprise, he will use the plant for producing a low-grade matte. There is an abundant supply of the silicious and iron ore that will be needed, near Ouray, and the Red Mountain district will furnish the copper. Recent development on the Indiana group, owned by Mr. Crawford, in the Red Mountain district, has opened a chimney of copper-silver ore. A promising find has been made in the Camp Bird. This ore, it is reported, was found in what had been thought to be barren ground about 1200 ft. from the surface in the west workings from the fifth or adit-level.

Teller County

The Elkton Con. M. & M. Co., operating the Elkton mine at Cripple Creek, paid an extra dividend of ½c. per share as well as the regular dividend of 1c. per share on October 14. Ore said to be remarkably rich is being taken from a new level, below the old water-level.

A new crusher is to be purchased for the Jo Dandy mill at Cripple Creek, according to newspapers, as the Blake crusher now in use is not heavy enough to crush large pieces of ore. Thomas Kavanaugh is manager of the mill.

The Gold Dollar estate, on the east slope of Beacon hill, shipped 1100 tons of ore in September. All of the ore was shipped by lessees, the Union Leasing Co. making the largest shipments. The company received about $2200 in royalties.

Reports from the mills and smelters give a total production of 76,805 tons, with an estimated value of $1,316,683 for the Cripple Creek district in September.

Frank Caley has purchased a 12-drill Imperial type electrically-driven compressor from the Ingersoll-Rand company for use at the Jerry Johnson mine. It is a duplicate of the compressor recently obtained for the Modoc mine. Owen Roberts, a lessee of the Gold King, is planning to buy a similar compressor, according to reports from Cripple Creek.

The Metallic M. & L. Co. is to resume work in a few weeks at the Hiawatha property, according to reports from Cripple Creek.

The Humphries-Thompson syndicate, which has opened a promising vein on the bottom level of the Ruby mine probably will resume work by November 5. The retimbering of the shaft has almost been completed.

RICO, COLORADO.

IDAHO

Idaho County

The Idaho Realty, Power & Mines Co. is about to put in an electric plant at Dixie. The company has enlarged its ditch for the mine, which is a placer property. The elevator is ready to run, and active operation will be commenced as soon as the water starts running in the stream. S. R. Gayton is manager for the company.

Lemhi County

The Pittsburg-Idaho company paid a dividend of 4c. per share, on October 15. The dividend was the third for one year. Instead of making the dividend larger, the directors decided to pay the 4c. dividend and make a payment of $16,000 on the bond issue of $23,000. It is reported that the company will declare a dividend of 7c. in January. The property is near Gilmore.

Shoshone County

Work has been resumed by the Clear Grit M. Co. on its property in the Beaver district, a mile from Delta. R. B. Bohannan, of Spokane, Washington, is manager for the company.

MONTANA

Lincoln County

(Special Correspondence.)—The Libby Placer Mining Co. is now operating steadily with the new hydraulic plant which was recently completed and which has a capacity four times greater than the old outfit. Operations will be carried on as long as the weather permits. This company owns nearly 1000 acres of placer ground on Libby creek. The Comet Placer M. Co., controlled by practically the same stockholders, has closed down for the present, owing to lack of water.

George Chew, of Spokane, owner of the old Vaughan & Greenwell placer claims on Libby creek, is taking steps to have his holdings patented, the papers in the case having already been sent to the land office by Gray & Rowland, attorneys. There are five claims in the group.

Libby, October 14.

NEVADA

Esmeralda County

The Round Mountain M. Co. in the quarter ended August 31 made a net profit of $34,763, according to a statement recently issued by J. R. Davis, president and manager of the company. In this period the company mined and milled 13,084 tons of ore, at a cost of $58,915, or $4.50 per ton. The gold recovered amounted to $90,014, or $6.88 per ton. There were miscellaneous earnings of $3364, or 28c. per ton, making the gross earnings $93,678, or $7.16 per ton. Mining costs have been reduced from $6.39 per ton to $4.50 during the quarter. The new mill has a capacity of 175 tons of ore per day. The company has extended the cross-cut on the 450-ft. level 528 ft. and has opened the downward extension of the foot-wall orebody on the 135-ft. level. What is believed to be an important orebody has been opened at the 700-ft. level. The Secretary of the Interior, says the report, has not disposed of the petition of the Round Mountain Sphinx M. Co. for the issuance of a writ of certiorari to review his decision denying a protest against the issuance of a patent to the Round Mountain M. Co. for the Great Western No. 1 claim.

Lyon County

In another month the ore-sampling mill of the Mason Valley M. Co. will be completed, according to a statement of Jules Labarthe, general manager for the company. The mill will do custom business.

By building a custom smelter at Thompson, near Wabuska, a station on the Tonopah & Goldfield railroad, the Mason Valley Mines Co. will start the Yerington district on its career as a regular producer of copper. Its output will not be an important factor in the metal market at present, and its production will grow very slowly. There is no property in the district that is prepared to put out a large tonnage. All of the ore is a direct smelting product and only a small percentage of that so far developed averages higher than 3½% copper.

The largest body of ore that has been blocked out is in the Blue Stone mine, owned by J. R. De Lamar. It is said to contain from 1,500,000 to 2,000,000 tons, averaging about 2¾% copper.

After an inspection of the company's property, Duncan MacVichie, engineer for the Yerington Copper Co., has advised the directors to put the property on a producing basis in order that it may earn some of the money required for development.

Nye County

The Tonopah Belmont Development Co. in September made a net profit of $144,972, according to the official report recently issued. A total of 9816 tons of ore was shipped to the mill and smelter. The production of gold was 3712 oz. and of silver 388,227 ounces.

The Tonopah M. Co. in September, according to the official report, made a net profit of $132,349, the smallest since July, when the profit was $120,415. During the month a total of $268,515 oz. of gold and silver bullion, valued at $198,370, and 109 tons of concentrate, valued at $44,425, was shipped. The ore shipped to the mill amounted to 14,020 tons and was valued at over $19 per ton.

TONOPAH, NEVADA.

Preparations are being made on the Kendall-Douglass lease on the Consolidated property for the erection of a 20-hp. electric hoist which is now on the way.

Rich ore has been discovered recently on the Kendall lease on the Joker property, now owned by the Big Four company.

A new company is being formed in the North Manhattan part of the Manhattan district for the construction of a mill to serve all mines on the northwest slope of Bald mountain and vicinity. The J. D. Johnston company is one of the more active organizations in that district. The J. D. Johnston company has been doing some retimbering on claims of the old Butler company. Arthur S. Putney is superintendent for the company. Rich ore has been found on the Gray Wolf claims, owned by Thomas S. Jones and associates.

It is reported in Manhattan that S. W. Steffner and I. P. Carpenter will soon break ground for a new mill to be situated near the Consolidated workings.

Bath brothers have taken a lease on block No. 1 of the Earl, in the Litigation hill section, and are taking ore out through their old shaft on the Union No. 2 property. The ore is said to assay $50 per ton.

Storey County

The total production of the North End mines on the Comstock lode for the last week was $35,681, the Ophir leading with a production of $23,737. In the Ophir mine ore from the 2100-ft. level stope averaged $85. The shipments for the week included 377 tons of second-class ore to the Kinkead mill. Shipments from the Mexican included three cars of first-class ore to the smelter. The winze used jointly by the Sierra Nevada and the Union was sunk 12 ft. during the week and is now 602 ft. below the 2000-ft. station. In the Con. Virginia the southwest prospecting drift on the 2550 ft. level was extended 18 ft. during the week, and some timbering was done. The hydraulic elevators in the C. & C. shaft ran successfully throughout the week, and the water was 297 ft. below the 2550 ft. station at the end of the week. The drift in the old Union Mexican east cross-cut in the 2450 ft. level was cleaned up for 150 ft. Work for the temporary pump station was continued. A south drift is being driven on the 2500 ft. level of the Mexican to take air from the Mexican winze to the old Union Mexican winze for pumping. Remodeling the buildings at the Ward shaft continues, and on the 2200-ft. level cutting out beside the shaft is under way for a pipe line from the bulkhead to the pump compartment. The east cross-cut on the 1200-ft. level of the Overman was advanced 9 ft., and the joint Overman and Seg. Belcher east cross-cut was pushed 9 ft. The joint Imperial-Confidence-Challenge shaft was sunk 6 ft. At the 800-ft. level, No. 1 Brunswick shaft, operated by the Chollar company, the east cross-cut was advanced 11 ft. At the Yellow Jacket mill 794 tons of Crown Point ore was run through the bins and a clean-up finished the No. 2 run from the Crown Point mine. At the Belcher mine a total of 85 ft. of retimbering was done. Crown Point shipped 315 tons of ore to the Gloryhole from the Yellow Jacket shaft, and hoisted a total of 473 cars of ore averaging $10. Work was confined to the 1400-ft. level and in repairs to south drift No. 1, where much low-grade ore was saved.

OREGON

Josephine County

The Greenback gold mine, twenty miles north of Grants Pass, has been bought by Robert C. Robertson and Frank C. Robertson, of Parish, New York. All claims against the property have been paid through C. H. Clements and R. G. Smith, attorneys for the purchasers. The mine is reported to have produced over $2,000,000, and in the past many men were employed there.

UTAH

Salt Lake County

The Utah Con. Copper Co. has declared a dividend of 50c. per share. It is reported that there will be a semi-annual disbursement of this size.

About 11,000 tons of ore per day is being shipped over the Bingham & Garfield, the new Utah Copper Co. railroad, from the Bingham camp to the smelter at Garfield. In addition to this ore, state recent press reports, the Denver & Rio Grande road is carrying 17,500 tons of ore per day for the Utah Copper Co., bringing the daily shipments to the largest figures ever reached by the company.

Tooele County

The lead smelter of the International S. & R. Co. at Tooele will be in commission early in the new year, recently stated E. P. Mathewson, general manager for the company. The construction of the smelter is progressing in a satisfactory way. Mr. Mathewson stated that reverberatory furnaces in the copper smelter are doing better work than ever. A record of 328 tons per furnace per 24 hours recently was made. A quartering and bucking department will be added to the sampling plant of the smelter. A 400,000-gal. reservoir is being constructed in Pine canyon.

WASHINGTON

Ferry County

(Special Correspondence.)—Ben Hur shaft is down 406 ft. Sinking from the 300 to the 400-ft. level and timbering was accomplished in 24 days, making the best record ever made in the camp. Work will be resumel in the Morning Glory mine in a few days. During the month of September the Republic Mines Corporation shipped 21 carloads of ore from the Surprise and 3 carloads from the Lone Pine mine. During the first 13 days in October 14 carloads were shipped from the Surprise and 1 from the Lone Pine. The Surprise shipments averaged in value about $40 per ton, and the Lone Pine shipments assayed from $15 to $22 per ton.

In Keller camp rich silver-copper-lead ore has been discovered in the Tenas mine, formerly known as the Iconoclast. Operations have been resumed in the Kettle River mine, near Rockcut, under the supervision of W. S. Bliss, a new manager, whose address is Orient, Ferry county. The ore contains gold, silver, copper, lead, and zinc. Unless the character of the ore changes, a modification will be made in the mill for the purpose of separating the zinc from the other minerals.

Republic, October 13.

Okanogan County

(Special Correspondence.)—Robert L. Norris, of Schenectady, New York, has arrived at Chesaw recently and will succeed R. Irwin Plomert as resident trustee and manager for the Molson Gold Mining Co., Meyers Creek district. The company is preparing to patent its holdings.

Chesaw, October 13.

CANADA

North Canada

Reports from Porcupine, Ontario, state that R. S. Elmsley, of Ottawa, Ontario, and Richard White, of St. John's, are fitting out a vessel for further exploration of quartz and placer gold deposits, they are said to have discovered on a previous trip to Baffin's Land and northern Labrador.

Ontario

The new shaft has been started on the Pearl Lake mines at Porcupine. It will be driven to a depth of 400 ft. before the first station will be cut, and cross-cutting started.

The Kerr Lake company has declared a regular quarterly dividend of 25c. payable December 15 to stock of record December. Three months ago an dividend of 15c. and six and nine months ago, extra dividends of 25c. each, were declared.

(Special Correspondence.) — The Swastika district is becoming increasingly prominent as a gold camp. There are now about 3000 people there and some 17 mines in most of which preparations are being made to install modern mining plants. The Homestead Mines Ltd. is capitalized at $2,000,000, and has 78 acres which has been under development for the last four months. Camp buildings have been erected and an adit of 60 ft. run into this hill. Frank L. Culver of the Beaver mine, Cobalt, is president of the company. The Lucky Cross is installing machinery preparatory to sinking a shaft, and has found free gold in a number of veins.

At the annual meeting of the Consolidated Mining & Smelting Co., held in Toronto, October 12, the financial report showed that the gross value of the output was $4,437,901 as compared with $5,911,767 for the previous year, a decrease being shown in all the metals. This was due to the working out of the St. Eugene, and the fire in the Slocan, which closed down the Kaslo and Slocan railway. Operations yielded a net profit of $202,278 as compared with $309,945 the previous year. The amount of $438,354 was expended on development and $193,342 written off for depreciation. Since the close of the fiscal year arrangements have been completed with the liquidators of the Le Roi for the purchase of all its properties in Rossland.

Toronto, October 13.

Yukon

(Special Correspondence.)—E. E. Stockton, of the Auditor-Generals Department at Ottawa, who has just returned from Dawson, after auditing all the Government accounts, including the gold royalties, states that the gold production of the Yukon district this year will be about $4,500,000 or $250,000 over the output in 1910. The Yukon Gold Co. had seven dredges in operation and was also extracting gold by other methods and other companies were also doing considerable work. Mr. Stockton anticipates a slow but steady increase in the gold production of the Yukon.

Toronto, Ont., October 13.

MEXICO

Chihuahua

Additional machinery will be purchased for the Esmeralda-Parrall M. Co. property. The output will be considerably enlarged and boilers, a hoist, and an air-compressor will be secured. The mine recently was inspected by William P. Fairman, of Philadelphia, president of the company. Wade Armstrong is superintendent of the mine.

The control of the Veta Colorada recently passed into the hands of what formerly were the minority stockholders. G. J. Ashe, of Knoxville, Tennessee, the new president of the company, is about to visit the property on a trip of inspection.

The National M. & S. Co. is now operating the Lustre Magistral, one of the largest mines in the Parral district, and is employing a large force of men in development.

The Mines Company of America, which will cut its next quarterly dividend from 2½ to 1½%, is planning to use the money thus obtained in buying other properties in Mexico.

Mills in the Inde camp are running full capacity, according to the latest press reports, and the mines are making their usual shipments.

Rienze W. McFarlane is making an examination of the San Diego mine, in the Santa Barbara district, and has temporary charge of the property.

NACOZARI, MEXICO.

Sonora

During the six months ended June 30, according to a report by A. V. Dye, U. S. Consul at Nogales, titles were issued to 977 mining claims in Mexico, covering a surface area of 36,591 acres. Of this number about one-fourth were issued in the State of Sonora, the exact number being 244 claims, covering an area of 13,133 acres. In Sonora the largest number were located in the Altar district, that is, 43 claims covering 2518 acres, although in the Montezuma district the 34 titles issued covered an area of 2923 acres.

While there was some cessation of development during the period, most of the producing mines kept up their normal output. The exports of minerals to the United States passing through the northern frontier ports of Sonora during the six months were as follows: gold, $1,432,707; silver, $1,857,478; copper, 33,299,986 lb., valued at $3,905,595; lead, 3,023,438 lb., valued at $69,189; zinc, 154,637 lb., valued at $3337; total, $7,268,306.

Shipments of ore and bullion from northern Sonora for September reached the total value of ₱1,468,000, against ₱1,500,000 for August, and ₱1,453,500 in July. The gross weight of September exports was 9996 tons, against 14,332 tons for August. The Nacozari was the largest shipper of ore, with 203 cars. The El Tigre made one shipment of bullion and silver precipitate to the Monterey smelter, valued at ₱59,000.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. J. Gormley is in San Francisco.

D. W. Brunton has gone to Japan.

N. J. Martin was in San Francisco.

F. H. Morley has returned to Denver.

W. J. Loring has left San Francisco for London.

F. M. Woods will be in San Francisco tomorrow.

F. M. Simonds is on professional business in Cuba.

J. F. Newsom has returned from South America and New York City.

H. E. West has moved from Haileybury, Canada, and is now in London.

F. L. Ransome is at Tombstone, Arizona, from where he will go to Ray and Miami.

C. W. Goodale is with the American Institute of Mining Engineers Japan excursion.

Howard D. Smith has gone to Midway on an extensive examination of the oilfields.

William R. Jewell has moved his office to 317 Brower building, Bakersfield, California.

J. Malcolm Maclaren was in San Francisco over Sunday and has returned to the Mother Lode.

A. D. Foote recently underwent a severe operation in San Francisco, but is making a good recovery.

George Otis Smith was in San Francisco for the meeting of the Institute and has left for Chicago, stopping in Nevada.

H. W. Edmondson has just returned from an examination of the Pioneer group of mines near Goldroads, Arizona, for Eastern people.

Corey C. Brayton was in San Francisco to attend the excursion to Bohemian Grove and the Mining and Metallurgy Society dinner.

Robert Scott has returned to San Jose, California, having erected a 25-ton quicksilver plant for the Mercury mine, Nye county, Nevada.

Jesse J. MacDonald is traveling in Arizona and other States, and later will be with the Utah Copper Co. at Garfield, Utah, for some time.

Inquiry is being made for the present address of J. F. Staver, a California graduate of '91, who is requested to communicate with this office.

Edward M. Rabb, Jr., has gone to the Jackson district, Graham county, Arizona, on professional business, and expects to be at Tucson the latter part of this month.

John T. Reed, of Lovelock, Nevada, has just completed an examination of mineral lands within the Central Pacific railroad grant in Nevada in the interest of the Government.

Howland Bancroft has left South America, where he has been examining mines for the past few months, and is now on his way to Mexico, where he will be for the next few weeks.

William F. Kett has been appointed by the directors of the Mountain Copper Co., Ltd., as general manager of their business in California, with headquarters in San Francisco. Mr. Kett has held the position of assistant general manager for the past six years, and now succeeds Lewis T. Wright, who recently resigned.

Alfred H. Brooks, of the U. S. Geological Survey, was in San Francisco this week on his way from Alaska to Washington, D. C. It is expected that Mr. Brooks will continue in charge of the Alaskan work of the Survey, having stated his preference for that position both in his cabled reply to George Otis Smith, Director of the Survey, and at their conference here this week, when the question of a successor to C. W. Hayes as chief geologist was considered.

The San Francisco members of the Mining and Metallurgical Society of America entertained the visiting members and distinguished guests at dinner at the Fairmont hotel on October 16. Those present were Ralph Arnold, E. H. Benjamin, F. W. Bradley, D. W. Brunton, H. F. Bain, C. C. Brayton, Albert Burch, S. B. Christy, G. H. Clevenger, F. G. Cottrell, E. T. Dumble, Francis Drake, H. S. Drinker, Courtenay De Kalb, J. B. Farish, D. L. H. Forbes, C. W. Goodale, G. H. Garrey, E. A. Hersam, Ross B. Hoffmann, W. R. Ingalls, Chas. Janin, W. J. Loring, L. W. Malcolmson, Bernard MacDonald, J. M. Maclaren, C. W. Merrill, F. H. Morley, W. W. Mein, G. W. Metcalfe, S. W. Mudd, W. S. Noyes, E. W. Parker, W. C. Ralston, T. T. Read, D. M. Riordan, R. S. Rainsford, J. W. Richards, R. W. Raymond, M. L. Requa, F. L. Sizer, A. W. Smith, G. O. Smith, J. W. Struthers, W. L. Saunders, Whitman Symmes, W. A. Wilson, C. G. Yale.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press.

Mechanics' Lien on Oil Wells.

The Indiana statutes providing for a mechanic's lien for materials furnished for any structure, does not authorize a lien on the interests of a lessee under an oil lease for coal furnished a contractor employed by the lessee and used by him as fuel in drilling an oil well on the leased premises.

Niagara Oil Co. *v.* McBee, (Ind.) 91 Northeastern, 250. March 1910.

Notice of Injury Under Employers' Liability Act

The New York employers' liability act provides that no action shall be maintained under the act for injuries to, or death of a servant, unless notice of the time, place, and cause of the injury is given to the employer. Under this statute a notice was held sufficient where it stated that the death of a servant occurred on the morning of August 13, 1909, in a chamber of the employer's mine, known as the Big John room, while the servant was in the discharge of his duties as a laborer in the mine, taking down props which supported the roof whereby it suddenly caved in and buried him, and that the cause of the injury was the negligence of the owner's superintendent in directing the servant to take down the props to enable another workman to shift the tramway or track, instead of directing the other workmen to remove the track in sections. A notice under this section otherwise sufficient, is not rendered insufficient, or defective because it states several additional alternative causes of the injury, and which additional causes the plaintiff fails to prove on the trial of the case.

U. S. Gypsum Co. *v.* Sliwienska, 183 Fed. 688. Dec. 1910.

Mining Lease—Ownership of Fixtures or Mining Machinery

A lease of a mining plant and machinery provided that the lessee should keep the plant in good repair and make all improvements, repairs, and replacements necessary to keep it in good running order and repair. It also provided that such improvements, repairs, and replacements should become the property of the lessor. On the construction of this lease in an action between the lessor and the lessee, the Court of Appeals of Missouri held that the agreement that the improvements, repairs, and replacements should become the property of the lessor did not apply to a dummy elevator and sludge table added to the plant by the lessee, and which were not necessary to keep the plant in good repair and which could be removed without injury to the realty, as these were trade fixtures. The lessee also had the right, at the expiration of his term, to remove a mining plant and machinery erected by him to mine, clean, and prepare ore for the market, as these were personal property.

Weeks-Betts Hardware Co. *v.* Roosevelt Lead & Zinc Co., (Missouri) 134 Southwestern, 35. Feb. 1911.

New Type of Steam-Shovel

An interesting new type of revolving steam-shovel has been introduced by the MARION STEAM SHOVEL Co. which is provided with an unusually long boom. This permits the making of wide cuts and the dumping of the excavated material far enough to one side so that the ore thus uncovered may be mined out without being partly under the spoil bank. This eliminates the handling of the overburden in cars and reduces the labor required to the shovel crew. When opening a new field, these shovels are capable of digging a thorough-cut and depositing the excavated overburden all on one side within the limits of their reach. After the thorough-cut is well started, the uncovered material can be removed, so that when the shovel completes the one cut it can return on another, this time depositing the overburden in the open pit or excavated space where the coal, for instance, has been taken out. This will permit a wider cut to be made the second time, on account of there being more room, and as the machine revolves in a complete circle the only necessity, in working back and forth against the face, is to shift the track each time for it to work on when returning. It is desirable, however, to take out the ore immediately following the shovel as it advances, so that no time is lost or delay occasioned at the end of a cut. Another superior feature of these special shovels over the ordinary type of excavator is that they will handle overburden of a far greater depth and width of face. They are simple in design and easily controlled. The entire upkeep and operating expense is surprisingly small, which makes it possible now to handle at a splendid profit many stripping enterprises hitherto considered unworthy of development. The shovels are provided with $3\frac{1}{2}$-cu. yd. dippers, and the boom is 65 ft. long. This allows making a cut 148 ft. diam. at 30 ft. elevation or 110 ft. diam. at the bottom of the pit. The approximate working weight of the shovel is 146 tons. The boom is of the all-steel type, of the most modern design, well trussed and braced. It is pin-connected to step castings resting on the two inner sills of the rotating frame immediately over the roller path, thus transmitting direct to the truck frame all the strains. Rods connected to the middle of the boom and anchored at the fore corners of the rotating frame stay the boom in starting and stopping. The crowding engines are double, reversed, and controllable by a central valve of the balanced-piston type. They are of the same design and type as the rotating engines, and are geared direct to the shipper shaft, which is machined square for the gears and turned for the shipper shaft and dipper-handle yoke block bearings that are provided with bronze bushings. The dipper handle is of the combination steel and oak type. Both sides of each member are armored with steel plates and covered top and bottom with heavy steel bars. The racking is of manganese steel, bolted and riveted to the bars on the under side of the handle. An end socket casting is secured to the handle and pin-connected to the dipper back, thereby allowing the pitch of the dipper to be changed to suit the work.

REVOLVING SHOVEL WITH LONG BOOM.

EDITORIAL

A SEMI-TECHNICAL contemporary, referring to the harvest moon, says that it occurs at the autumnal equine. It is doubtless proper to greet this with a horse-laugh.

IN OUR editorial pages of October 14 *The Mining Financial News* was, through a blunder, referred to as *The Mining Age*. Having thus unintentionally injured the latter journal, we hasten to make this acknowledgment in reparation.

MISSOURI SCHOOL OF MINES celebrated its fortieth anniversary at Rolla, Missouri, this week by laying the cornerstone of a new building, thus emphasizing progress rather than self-gratulation. The School has a record of honorable achievement, and we extend our congratulations for the successes of the past and good wishes for the future.

SUCCESS as a result of persistence is the lot of the Ahmeek Mining Company, which, though organized in 1880, has recently declared its first dividend. With a capital of $1,250,000, of which but $850,000 has been paid in, it has persisted, opening the present workings in 1902 and paying for improvements from current earnings. We hope its period of prosperity may be equally protracted.

BONDS are becoming popular at the expense of shares in these days of financial uncertainty. Funds are continually coming in to the market for investment, but wise investors, realizing that the chances of a share market that is kaleidoscopic in its changes are all against them, are seeking securities that are reasonably stable. Financial house-cleaning is remarkably like the ordinary kind and the effects are equally disquieting to all concerned.

RAILROADS are, to some degree, an index of general business conditions, and it is encouraging to note that the first week of October shows an increase of 0.7 per cent in gross earnings, compared with the same period of last year. The official summary for the year ended June 30, 1911, shows that total operating revenues were 0.6 per cent less than the corresponding period of 1910, while operating expenses were 2.8 per cent higher, corresponding to a decrease in operating income of 8.8 per cent. It is interesting to note that Southern roads prospered, while the reverse was true of Western roads, the former recording an increase of operating revenue of 3.3 per cent, while the latter exhibited a decrease of 2.7 per cent.

TO THE business type of mind there is necessarily something adventitious in the viewpoint of the scientist. To all such the action of Mr. Alfred H. Brooks in refusing promotion to the position of chief geologist of the United States Geological Survey, as recorded in our 'Personal' columns last week, holds something of the incomprehensible. Yet from the scientific viewpoint Mr. Brooks' decision was a natural and fitting one. Through years of painstaking achievement as chief of the Alaska work of the Survey he has indissolubly associated his name and personality with that work, and naturally feels that he cannot afford to leave it uncompleted to take up new responsibilities. We are proud that in our Government service men are to be found to whom the work is greater than opportunity for personal advancement, and it is good to believe that Mr. Brooks is not alone in this regard.

THE Mother Lode district of California is as productive of interest as it has been of gold, and the recent taking over of the Plymouth mine by Bewick, Moreing & Company is a matter of more than passing note. The Plymouth was worked to the 1700-foot level before the fire which led to its being closed down many years ago, but was showing a good profit, and the outlook for its development into a steady producer is correspondingly bright. And the advent of English capital into gold mining in California is a matter of no less note. We extend the purchasers our good wishes for the profitable outcome of their venture and the hope that it may lead to closer relations in the future.

DISSATISFACTION with the land laws of the United States is daily becoming more acute. The need of revision of the land laws, as applied to Alaska, has recently been the subject of discussion by both the San Francisco and Philadelphia sections of the Mining and Metallurgical Society, and the same topic has been a feature of the discussions at the American Mining Congress during the week. As a means of clarifying and unifying the ideas of the members of the mining profession such discussions are excellent; as a means of securing remedial legislation they are ineffective. If a committee from one of the national societies would draft new laws and submit them to Congress through their representatives, definite results would be attained.

PROPHECY, to judge from the experiences of prophets since the time of Moses and Aaron, is not an altogether satisfactory vocation, but if the impulse is irresistible it is best to be an optimistic prophet. Some such impulse must have actuated the *Boston Commercial* when, as recently, it prophesied that copper production for this year will reach 1925 million pounds, while the consumption will amount to 2225 million pounds, which leads to the deduction that a new Calumet & Hecla, a new Nevada Consolidated, and a new United Verde must be provided each year to keep up with the growing consumption. With electrolytic copper at 12.08 cents on October 13, this is a comforting prophecy. Who would not be a prophet rather than a statistician!

LEARNING by experience, though the most effective method of acquiring accurate and trustworthy information, is but a slow task. In the estimation of costs experience is the only sure guide, for usually the data available are fragmentary or incomplete, and it is difficult not to overlook some essential factor, the existence of which could only be known to one thoroughly familiar with the conditions which circumstance the case in question. Engineers, having acquired a large fund of accurate information, often, not unnaturally, regard it as part of their assets and refuse to make public what has been secured as the result of much effort. Mr. Charles T. Hutchinson's discussion of the cost of constructing stamp-mills, given on the following pages, is all the more noteworthy, therefore, and even those whose interests lie outside of stamp-milling can read it with interest and profit. Mr. Hutchinson rightly emphasizes the important part which small and oftentimes unnoticed factors may play in increasing the cost of construction. The handling of timber by manual labor, the working under unusual and unsatisfactory conditions, the accentuation of unfavorable and the lessening of the effect of favorable conditions, all may combine to raise costs far above the preliminary estimates. We cannot have too much of definite information of practical value.

TUNGSTEN is a metal once classed as rare, but which has become of such importance in the industrial world that the not inconsiderable sum of 5289 tons of 60 per cent tungsten trioxide ore was produced in 1909, of which the United States contributed nearly one-third, corresponding in value to over a half million dollars. Colorado has long been the leading State in the production of this metal, its whole output coming from Boulder county, but California is a notable producer also, San Bernardino county having a number of small mines. On another page Mr. John H. Williams briefly describes some of the San Bernardino county deposits. Tungsten is not only important in the manufacture of ferro-alloys, but also in many branches of chemical technology, and though the industry is not large, measured in terms of tons and dollars, it is a matter of much interest.

THE American Mining Congress has been meeting in Chicago this week, and a notable program was provided. The delegates were welcomed by the Governor of Illinois and the Mayor of Chicago, and on Wednesday the president, John Dern, read his annual address, which was followed by the reports of the committees on workmen's compensation and on Federal legislation, and by an address by Martin D. Foster, chairman of the House Committee on Mines and Mining. In the evening J. A. Holmes discussed the problems of the mining industry, James Douglas described what is being done to protect the lives of coal miners, and E. H. Benjamin described the mining industry of California. Thursday was given over to discussions of the coal industry. Friday morning Alaskan problems were discussed by a notable list of speakers, including A. H. Brooks, and at the afternoon session the public lands in the West were the topic, the governors of Utah and Arizona being the principal speakers. The notable features of the evening session were the report of the committee on a general revision of the mineral land laws, which is given in full on another page, and an address by W. L. Fisher, Secretary of the Interior. On Saturday morning 'The Federal Government and the Mining Industry' was the topic upon which William H. Taft, President of the United States, was to speak. It goes without saying that much good must flow from so notable an assemblage of speakers, and the American Mining Congress may congratulate itself upon attaining a higher level of influence than ever before.

Technical Discussion

At a recent election in California a constitutional amendment granting equal suffrage to women was enacted by a small majority. It is not our purpose to discuss the wisdom or unwisdom of this departure, though much might be said upon the topic, but allude to it in passing merely to note that, so far as a Californian is concerned, it marks the passing of the only public topic upon which it was possible to excite a vigorous general discussion. Those whose memories extend back to the period before the Civil War recall with interest and some amusement now the bitter enmities that then arose from differences of opinion on public questions of the hour. In one way or other a broader spirit of toleration has grown up, a willingness to concede to the other man a right to his peculiar views, even if they interfere slightly with our own, that marks a more mature stage of mental development. But it would almost seem as though the law of simple harmonic motion governed the movements of society, and that the pendulum, having swung free beyond the median point must travel an equal distance on the other side of it. Too great toleration may lead to a *laissez faire* attitude of mind which is prejudicial to the best interest of the individual and of society as well. In short, mental indolence threatens us. This is even more true when limited to the technical world. No more striking contrast could be desired than that between the discussions recorded in the proceedings of the Institution of Mining and Metallurgy and the Chemical, Metallurgical and Mining Society of South Africa and those which mark the meetings of the American Institute of Mining Engineers and the Mining and Metallurgical Society. Discussions in the Institute are like snakes in Ireland, and the most notable ones in the Society deal with the problem as to whether local sections, supposedly composed of competent engineers, can be trusted to comport themselves properly without rigid supervision. In the columns of the *Mining and Scientific Press* there have recently appeared many notable contributions, in which the authors set forth views or made public data that merit extended discussion before being unhesitatingly accepted. Yet comment and discussion upon them by our readers has been conspicuous by its absence, and a notable contribution, the value of which to the profession might have been greatly heightened by added perspective afforded by being seen from more than one viewpoint, has apparently passed unnoticed. The plea of 'too busy' is a common one, to which the most adequate reply is the retort of an instructor during our college days: "Are not your days also twenty-four hours long, like those of others?" Men have always found opportunity for whatever they really wish to do. And that engineers should cease to wish to take an active part in the development of their profession, is so clearly contrary to their best interests that we find it impossible to believe that it is actually the case.

Revolution in China

Mining engineers are cosmopolitan by nature and training, and therefore may be expected to feel keener interest than ordinary men in events upon the other side of the globe. During the past two weeks the actual news which has emanated from China has been of grave import, but it has been buried in so much journalese and overlaid with so much that is obviously incorrect that our readers will perhaps be glad of a winnowing of the wheat of fact out of the chaff of newspaper report.

Many will wonder why this particular time, when the institution of a constitutional form of government was in steady progress, should be marked by an outbreak of rebellion against the Manchu monarchy, but the underlying reason is not far to seek. Briefly, it is a double one, the growing control of provincial affairs by the national authorities, and the popular feeling that the course being followed by the national government in the creation of powerful foreign influences in the affairs of the nation through the agency of large foreign loans, is an unwise policy, have led to an attempt to overthrow those now in control of the reins of government. Several facts should be kept in mind. The authority of the Chinese Government along the southern and southwestern borders of the Empire has been but shadowy always, and sporadic outbreaks of rebellion have been of constant occurrence since the accession of the present dynasty. Another significant fact is the lack of national unity in China. The Empire consists of an aggregation of communities, and the spirit of China is a community spirit rather than a national spirit. It must furthermore be noticed that while the government of China has been, in the past, theoretically a despotism, practically it has been democratic in the extreme, and the will of the people has, at all times and places, been able to make itself felt upon all matters that are of prime importance. Considerations of space forbid a more extended discussion of these vital factors, but the essential point to be kept in mind is the community spirit of the nation.

Some years since, when railroads were first being recognized as a powerful factor in the national development of China, it was proposed to construct a railroad from Peking to Canton. As foreign assistance, both technical and financial, was necessary, concessions were granted to foreign corporations, and as it would obviously have been unwise to allow a single nation to control so important a road, a concession was granted to Belgian interests for the northern half of the line and to American interests for the southern half. The details of the subsequent proceedings are not essential for our present purpose; the important fact is that the American interests sold their concession to the Belgians, thereby dealing a blow to American prestige in the Far East, the memory of which many years of fair dealing will not suffice to wipe out. The outraged gentry of the provinces traversed by the southern half of the line united and raised sufficient capital to buy back the concession. With commendable zeal they have endeavored to construct the road by their own efforts, but unfortunately with but little in the way of results, beyond the absorption of capital.

In its recent policy of nationalization of the railways the Chinese Government has, as is well known, negotiated a loan from British, French, German, and American sources for the construction of this and other lines of railway. The diplomatic fencing by which these nations endeavored to secure, each for itself, advantage in the terms of the international loan is another story. The essential fact is that a railroad, the right to build which had been bought by the influential merchants of the provinces traversed, was now to be built under national auspices and foreign supervision by means of a foreign loan. In return for the several million dollars which the gentry had already expended in their attempt to construct the road 50 cents upon the dollar was to be paid, and they would lose control of the line. Nothing better calculated to bring popular unrest to the boiling point could well have been devised. It would be idle to deny the existence of an anti-Manchu and an anti-dynastic spirit throughout southern China, just as it would be idle to deny the influence of many other factors, but the essential question is that of 'States rights' (which troubled the United States many years ago) to which the sting of 50 cents on the dollar has been added.

The outcome of the present uprising is still a matter of doubt. The rebel troops have gained successes, and Yuan Shih-kai, to whom the national authorities turned in their extremity, appears to be unwilling to commit himself to the defence of a government which so recently degraded him. What seems inevitable is what in England could be called a change of ministry. Prince Ching and his colleagues who belong to the Han-lin period of enlightenment are doomed to retirement, and men more in touch with modern progress must be brought to the fore. The most striking thing about the outbreak is, to one familiar with the Far East, the contrast in the attitude toward foreigners in 1911, as compared with 1900. In 1900 the national unrest exhibited itself as a blind rage, now it shows itself as an intelligent comprehension of the real problems, and, whatsoever the outcome of the present uprising, it is safe to say that notable progress toward the development of China into a modern power will be the result.

Report of the American Mining Congress Committee on General Revision of the Mineral Land Laws

EDMUND B. KIRBY, Chairman

This committee had assigned to it the work of securing action from the Congress of the United States upon the request of the American Mining Congress for a general revision of the mineral land laws. By the time the list of committee members had been appointed, and had conferred and agreed upon their plans, the winter session of Congress was so near its close that it was found that no effective action was then possible. During the special summer session there was a general understanding in the House and Senate that no general legislation was to be introduced, and this understanding prevented the consideration of our measure. It was, therefore, decided to undertake it early in the regular session this winter, at which time a joint resolution on the following lines will be introduced through our friends in Congress:

> That ——— Committee ——— is instructed to prepare and submit at this session a mode of procedure whereby Congress may undertake a general revision of the Mineral Land Laws of the United States in the way which will best promote the public welfare and meet the peculiar needs of the mining industry. The plan recommended should provide a practical means whereby Congress may utilize the best experience and judgment available in the industry and which will give the mining regions of the United States and Alaska ample opportunity for public hearings and the discussion of remedies.

In the meantime, your committee has taken up the matter with the Governors and United States Senators and Representatives of the Western States and Territories affected. It has informed them of the request of the American Mining Congress for a general revision and its reasons therefor, and of the aforesaid joint resolution to be introduced at the next session. The replies show that in this undertaking the American Mining Congress has not only no opposition, but the general approval and support of the public men of Western States, while a number of them show a keen personal interest in the matter. It is clear that, with the support promised, and the non-partisan nature of the measure, there will be effective action by Congress at the next session.

After Congress has empowered some committee to act, your committee hopes to have the opportunity of presenting to it such detailed information and suggestions as may aid in preparing a plan, whether for a commission or otherwise, which will be satisfactory to Congress and accomplish the ends desired. Your committee believes that this may be secured through a wisely selected commission, authorized to draft a revised code for the use of Congress. This commission should hold public hearings in the principal mining centres of the West and Alaska. It should call before it men prominent for their knowledge of prospecting, of claim locations, of mine operating, mine litigation, and the history of mining laws, and should invite opinions from the public bearing upon the specific points at issue. The authorities and experience of other mining countries should also be consulted, and the recommendations of the commission should be presented in the form of a fully drafted code.

It is clear that there is a best practical solution for each one of the difficult problems involved in a general revision of the mineral land laws, but in order to determine these best solutions, all opinions must be brought to a focus before some authoritative body which had the power of decision. Moreover, in order to assure the general approval and acceptance of reforms affecting so many varied interests, the personnel of this body should be such as to command confidence, and the mining communities should have opportunities to present their views before it. There is a wealth of learning and practical experience in the country, which is available for the work of framing a revised code, but it is distributed among many men and must be focused by the plan indicated. In order properly to follow up the business now under way, your committee asks that it be authorized to continue its work during the coming year. A memorandum is attached, explaining the request of the American Mining Congress for revision and the reasons for its action.

The American Mining Congress, representing the mining industry of the United States and Alaska, asks that Congress shall undertake a general revision of the mineral land laws. The mineral land laws of the United States and Alaska, framed in 1872 and interwoven with a mass of supplementary State legislation, differing in every State, fail to meet the present requirements of the industry. Moreover, they have developed various evils, the injurious effects of which are steadily increasing. These have become so serious as to retard the development of mining and create dissatisfaction and complaint everywhere.

At every annual session of the American Mining Congress during the past twelve years the prevailing discontent with the present code has been voiced by various resolutions calling attention to its evils and asking for the correction of this or that feature of the laws relating to mineral claims located upon the public domain. Such complaints, steadily increasing in volume, have found expression not only in the Mining Congress but also in the press of the mining communities, all the mining journals, in the societies of mining engineers, and, in fact, through every medium available for the expression of public sentiment. They have, nevertheless, been without result, for the reason that the mining laws are largely interdependent, and it is difficult, if not impossible, to correct one fault without involving the entire code. Moreover, the States affected, some of which have often attempted to make improvements, find that nothing effective can be done without the action of Congress. In short, patchwork is impossible, and a general revision is necessary.

Since the problems involved in the work are peculiar to the industry and are unusually difficult, it is evident that their satisfactory solution will require the aid of the most experienced judgment together with a free and direct expression of views by the mining communities themselves. Among the many questions which will arise during a revision are the following, which will illustrate the nature of the work: (1) the apex law, with the uncertainties of title and litigation caused by it. The latter includes not only the conflicts caused by the extralateral right, but also those occasioned by the consequent shapes of claims and the overlapping of lines. (2) The creation of definite procedure for acquiring rights to those claims in which the mineral is not near the surface and where discovery must in consequence be long deferred. (3) Adit locations and the uncertainties of title caused by them in neighboring claims. (4) The recent non-observance of the law of discovery. (5) The more or less complete non-observance, through various expedients, of the law of assessment. (6) The location of an unlimited number of claims by one individual. (7) Locations by proxy.

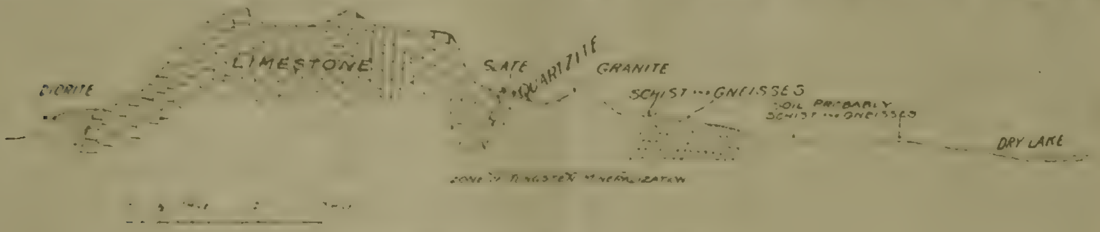
A general revision now will be particularly timely because of the public interest in conservation and the new legislation now under consideration for timber, oil, phosphate, and coal lands, and also power sites. To omit the mining code from any program for the betterment of laws relating to natural resources would be to pass by the field where relief is most urgently needed. The American Mining Congress therefore reached the following decision:

"That Congress be asked to undertake promptly a general revision of the mineral land laws, which in view of the difficult problems presented, should be in coöperation with the mining industry. The plan adopted for this coöperation should give all sections opportunity for public hearing and the discussion of remedies. The Mining Congress will suggest a practical plan for this purpose later on if desired."

Tungsten Deposits in San Bernardino County, California

By John H. Williams

The tungsten deposits are situated in the northeast part of San Bernardino county, in what is known as the Ivanpah quadrangle, a part of which is shown on the map. This region is interesting, not only by reason of its production, but also because of the facilities which it offers for the study of certain forms of tungsten ore deposits. In the tungsten mines the valuable mineral species found are: wolframite, a tungstate of iron and manganese; hubnerite, a tungstate of manganese; ferberite, a tungstate of iron; and scheelite, a calcium tungstate. The first three minerals are so intermixed that for an exact determination a chemical analysis is necessary. All ores are found over an area of $2\frac{1}{2}$ miles wide by 10 miles long, at elevations from 4000 to 6900 feet.



LIMESTONE
SLATE
QUARTZITE
GRANITE
DIORITE
SCHIST AND GNEISSES
SOIL PROBABLY SCHIST AND GNEISSES
DRY LAKE
ZONE OF TUNGSTEN MINERALIZATION

CROSS-SECTION THROUGH CLARK MOUNTAIN.

Clark mountain, in which the mines are situated, has a general northwest direction. The mountain is flanked on both sides by broad valleys. The upper part consists of limestone; adjoining the limestone are slate and quartzite; adjoining the quartzite the granite occurs, in which the tungsten deposits exist. Adjoining the granite are granitic rocks, mostly altered gneisses and schists. The tungsten ores are found solely within the area of the granite and granitic rocks; instances of their occurrence in the other rocks are not known.

VICINITY OF CLARK MOUNTAIN.

The granite is a coarsely-crystalline rock revealing to the unassisted eye feldspar, quartz mica, biotite, and hornblende. The granites have not a uniform texture and show strong evidence of foliation and other effects of dynamic action. The granite weathers easily and crumbles to a coarse sand. Nearly 2000 ft. to the east from the limestone-slate contact, a pegmatite dike runs parallel with the granite. The dike outcrops for five miles, and varies considerably in size, ranging from 40 to 150 ft. in width. In places wolframite and scheelite occur on the surface, but so far have not been developed. The schists and gneisses adjoining the granite to the east are far more regular and even in foliation. They are garnetiferous, showing stringers of sulphides and magnetite. At some places exposures of muscovite mica occur, sheets of 4 by 6 in. are common.

The ores are variable and their distribution in the granites irregular. Some of the ore-shoots occur as lenses, associated with quartz and calcite veins, running in every direction, with the exception of three parallel veins on the Jack claims. These three veins run parallel for nearly 1100 ft.; their average width is from 8 in. to $1\frac{1}{2}$ ft. A shaft down 66 ft. with nearly 42 ft. of driving, showed both faces and bottom of the shaft in good ore. Besides the smaller ore-shoots in the quartz-calcite veins, the tungsten ores are also deposited in quartz dikes from 10 to 45 ft. in width. The quartz dikes run partly northwest-southeast, and east and west. They contain both wolframite and scheelite in lenses and bunches. The lenses are very regularly distributed; in places I measured $1\frac{1}{2}$ ft. wide by 60 ft. long, averaging 12% tungstic acid. Another shoot was from 2 to 3 ft. in width, 24 ft. long, averaging 15% tungstic acid; this shoot contained wolframite and scheelite, the latter predominating. Both drifts on this last shoot are still in good ore. So far the deepest workings are at the Jack claims, showing the ore at a depth of 148 feet.

As regards the method of formation of the tungsten ore-shoots, the most reasonable and natural explanation is that they have been formed during the final stages of the cooling and consolidation of the granitic magmas, the mineralized waters and vapors given off filling the dikes and cracks due to the contraction of the cooling mass. It may be said of the district that the tungsten minerals are generally confined to quartz veins and dikes in the granitic rocks. Veins containing tungsten ores may occur anywhere within the area of the granitic rocks. In closing, I will say that the local conditions are admirably adapted for mining and milling, there being plenty of water and timber in the mountains. A concentrating plant is in course of erection, and the future outlook for this new tungsten district is promising.

Profitable Low-Grade Mines

The Under Secretary for Mines in Victoria, in his annual report, mentions that on the low average of $3\frac{1}{2}$ dwt. per ton the New Imperial Co. at Buninyong, and the Goldfields Consolidated at Bendigo paid dividends. The former treated 20,640 tons, yielding 3699 oz., and paid £750 as a dividend; and the latter put through 8483 tons, yielding 1498 oz., and distributed £996 to its shareholders. Surprisingly low average yields per cubic yard are now profitable in dredging. The Tewksbury Amalgamated Co., at Bright, won 4160 oz., worth £16,907, from 1,553,360 cu. yd. of ground, and paid £3325 in dividends. The average is only 1.1 grain per yard. The Porepunkah Dredging Co., at the same place, on an average of just one grain per cubic yard, paid £500 to its shareholders on a yield of 901 oz. from 421,071 cubic yards of ground.—*Queensland Government Mining Journal.*

Cost of Constructing Stamp-Mills

By Charles T. Hutchinson

Estimating on the cost of stamp-mill construction is not an exact science. No engineer or contractor can see far enough into the future to know beforehand what unusual or unexpected conditions will arise during the progress of construction, any of which will influence the cost of the work. A run of bad weather, the loss of a car of freight, incompetence or unreliability of teamsters, and a score of other things may raise the cost of construction well above the amount of the original estimate. Presupposing the existence of ideal conditions is both foolish and unbusinesslike, as the unexpected always happens, and the remark most often heard after a job is finished is, 'It cost me more than I figured.' It is not possible to impart by a brief written article the experience of years in judging, on inspection and study of local conditions, just how much to allow for carrying on each separate section of the work to be done; but the average cost of the various classes of work may be given and the various elements entering into construction costs may be briefly pointed out with the object in view of furnishing a basis by which a man familiar with the ground on which the mill is to be erected may prepare an intelligent estimate. The following has not been prepared for the large company, which is financially able to employ experts on construction to superintend the erection of its machinery. It is written primarily for those who contemplate the erection of small mills up to 20 stamps in size and who prefer to calculate systematically rather than indulge in guess work with its aftermath of disappointment.

There is an idea prevalent among mining men in general that stamp-mills can be built complete and turned over in running order for $1000 per stamp. This estimate may be correct in possibly one case in a hundred, but as no two sets of conditions governing the cost of mill construction are exactly alike, the use of this formula—if it may be so called—can only result in disappointment. The figures here given are based upon California conditions of labor and climate, the rate of wages being as follows per 8-hour shift: millwrights, $5; carpenters, $4; helpers, $3; masons, $5; machinists, $4.

Estimates

The elements entering into the cost of stamp-mill construction will each be treated separately and will all be found in the following summary which affords a good form for preparing estimates, and will be of aid in itemizing the factors which make up the total cost:

Material:

Cost of machinery f.o.b. factory.
Lumber for mill building f.o.b. shipping point.
Timber for ore-bin and battery-frame f.o.b. shipping point.
Shingles or shakes for roof.
Galvanized corrugated iron for sides and roof.
Doors.
Windows.
Building hardware.
Nails.
Cement.
Sand.
Broken rock.
Building bolts and washers.
Red brick.
Fire brick.
Fire clay.
Lime.
Tools for construction.
Freight charges on all the above from shipping point to railroad station nearest mine.
Hauling charges on all the above from railroad station to millsite.

Labor:

Cost of framing and erecting building.
Putting on siding; shingle roof; shake roof.
Iron siding and roof.
Setting doors and windows.
Erecting machinery.
Hauling building material and machinery on the ground.
Framing and erecting battery-frame; ore-bin.
Masonry retaining walls.
Concrete retaining walls.
Wood mortar-block.
Concrete mortar-block.
Concrete foundations.
Brick setting for steam-boiler.
Superintendence.
Timekeeper and office work.
Allowance for unforseen contingencies.

Machinery, Cost at Factory.—This information is the easiest of all to obtain and an inquiry sent to any reputable machinery manufacturer will meet with a prompt response. Modern trade catalogues are so carefully prepared and enter into so much detail that they are practically text-books on machinery construction and design. Most machinery houses maintain a competent engineering department, which will co-operate with prospective customers and assist them in making proper selection of the machinery best suited for treating their ores. Much time will be saved if prospective buyers will give the manufacturer a definite idea of conditions to be met in order that an intelligent estimate may thus be prepared. In sending an inquiry to a manufacturer for prices of mill equipment it is necessary that he should be informed as to (*a*) the character of the ore; (*b*) process that is to be used; (*c*) number of tons per day of 24 hours that it is desired to treat; (*d*) fineness to which it is desired to crush; (*e*) kind of power to be used.

If conditions require gasoline-engines for power, the altitude above sea-level at the millsite must be stated, as internal-combustion engines lose about 3% efficiency for each 1000 ft. rise above sea-level. If steam-power is to be used, the kind of fuel should be stated.

If electricity is to be used, the voltage must be stated if current is continuous; phase, voltage, and frequency must be stated if the current is alternating. If transformers are required, primary voltage and phase must be stated.

If water-power is to be used, the manufacturer must know the quantity of water available in cubic feet or gallons per minute or miner's inches, and the head in feet or vertical distance between point of intake and point of outlet. If pipe-line is already in place, length and diameter must be stated; and if not already in place, the length only will suffice.

Erection of Machinery.—This is an item which may cost from $30 per ton upward, depending upon the skill, ingenuity, and experience of the man in charge of construction. After all orders for machinery, building material, and supplies have been placed, instructions should be sent to the various concerns furnishing material, for the purpose of arranging a systematic schedule of shipping dates, so as to have the machinery and other material arrive on the ground as nearly as possible in the sequence in which it is required. There is seldom any gain in attempting to rush all shipments indiscriminately, as the confusion and chaos on the ground will result in more lost time and delay than is gained by quick though unsystematic shipments. If foundations are ready for the heavy machinery, the latter can be lifted direct from wagons and set in its proper place in the mill; otherwise it may have to be handled two or three times, and each time it is handled it costs money.

Bolts, washers, and small fittings when unpacked from shipping cases should be systematically arranged according to size. I have seen a $5 per day man spend an hour looking through a pile of small parts for a bolt, which should have had its place and been in it. Manufacturers generally send out a detailed statement with each shipment showing the contents of each package and case, so there is no excuse for waiting until a job is nearly ready to turn over and then find that the work must be hung up and a crew of men stand around idle, waiting for some small detail or missing part which may have been overlooked at the factory or lost by careless unpacking of material. Small parts and fittings liable to be lost or damaged by exposure to the weather should be housed. Even the crudest kind of a shed will save its cost many times over during construction of the plant. Building material, lumber, etc., should receive the same care and systematic handling as machinery and supplies. It is surprising how much time and money can be saved by a little foresight in this direction. A suitable framing yard should be prepared, as near the millsite as possible, in which all lumber can be systematically stacked on arrival according to width, thickness, and length, and where all framing can be done. Carrying lumber, heavy timbers, etc., back and forth by manual labor and trying to make a good job of framing when working on a side-hill are not compatible with low costs. When a man has spent much of his time and money in developing a prospect, and then has spent more time and hard work in financing his company, it can be readily understood why he is impatient to get started, but he should stop to consider that it nearly always costs as much money to try to force work ahead at a pace faster than circumstances will permit, as it would to go to the other extreme and delay matters.

Freight and Hauling.—These two items are governed entirely by local conditions, and no general information on this subject can be given; therefore, calculations must necessarily be made in each case according to circumstances.

CONSTRUCTION

Lumber for Mill Building.—The first cost of lumber is governed by local conditions and by the prevailing market price existing at the time the order is placed. The labor cost is also a variable factor, depending upon local conditions and the individuality of the workman himself, but the following rates will give a fairly close average approximation:

Framing and erecting mill buildings up to 30 ft. in height, $25 per M board-feet.

Framing and erecting mill buildings 30 ft. in height and upward, including setting roof-trusses, $35 per M board-feet.

Putting on 1-in. rough siding, battened, laying wood floor, etc., $20 per M board-feet.

It has been found by actual experience that a workman can work about half as fast at a height of 30 ft. or over as he can when below that point, and for this reason roof-trusses should always be framed and put together complete on the ground, then hoisted into place, and fastened, rather than be put together piece-meal in position.

Ore-Bin and Battery-Frame.—The same remarks as regards first cost of material apply in this case as in that for lumber for mill building proper. Dressed timber need not necessarily be used, although many builders prefer it on account of appearances. Occasionally builders prefer to have the timber furnished already cut and framed where machine tools are available, on the ground of economy, but it is questionable whether this course pays in the long run, since sufficient stock must always be left to allow for trimming when lining up the frame, camshaft bearings, and guide girts, which work cannot be done until the machinery is actually in course of erection. The cost of framing and erecting a battery-frame and ore-bin, including planking, is about $35 per M board-feet.

The following table will be of assistance in figuring lumber bills and the quantity required:

NUMBER OF FEET, BOARD MEASURE, IN LUMBER OF VARIOUS SIZES

Size, inches.	Length in feet							
	10	12	14	16	18	20	22	24
1 by 2	1⅔	2	2⅓	2⅔	3	3⅓	3⅔	4
1 by 3	2½	3	3½	4	4½	5	5½	6
1 by 4	3⅓	4	4⅔	5⅓	6	6⅔	7⅓	8
1 by 5	4⅙	5	5⅚	6⅔	7½	8⅓	9⅙	10
1 by 6	5	6	7	8	9	10	11	12
1 by 7	5⅚	7	8⅙	9⅓	10½	11⅔	12⅚	14
1 by 8	6⅔	8	9⅓	10⅔	12	13⅓	14⅔	16
1 by 10	8⅓	10	11⅔	13⅓	15	16⅔	18⅓	20

Shingles for Roofing.—The following schedule will apply to ordinary mill roofs: 250 shingles equal 1 bundle. Using pine shingles with 4 in. exposed to the weather, 1000 shingles per square will be required, weighing approximately 245 lb. If 6 in. be exposed to the weather, 670 shingles per square will be required, weighing approximately 165 lb. Sheathing should be 4 in. wide and spaced 4 in. apart. A square equals 10 by 10 ft., or 100 sq. ft. Labor cost per square is approximately $1.50.

Shakes for Roofing.—There is quite a variation in the size of shakes as furnished by the different mills, but the ordinary shake may be considered to be 6 in. wide and from 32 to 36 in. long. With 10 in. exposed to the weather, 250 shakes per square will be required. Sheathing should be 6 in. wide and spaced 5 in. apart. Labor cost per square is approximately $1.25.

Iron Buildings.—In many localities, particularly the desert country, where lumber is scarce and the cost is correspondingly high, galvanized corrugated iron, and sometimes flat painted iron sheets, are used for the sides and roofs of buildings. The price of this material varies with market conditions and locality. The following table will be of assistance in making calculations as to the quantity required.

NUMBER OF CORRUGATED SHEETS PER SQUARE

Length of sheet, inches.	3-in. corrugations. Width flat, 31 in. Width after corrugating, 28 in. Net covering width, 24 inches	2½-in. corrugations. Width flat, 30 in. Width after corrugating, 27 in. Net covering width, 24 inches	1¼-in. corrugations. Width flat, 30 in. Width after corrugating, 26 in. Net covering width, 24½ inches
60	8.572	8.888	9.231
72	7.143	7.407	7.692
84	6.122	6.349	6.593
96	5.357	5.555	5.769
108	4.762	4.938	5.128
120	4.286	4.444	4.616

If material is painted, add 20 lb. per square to allow for paint. No. 26 is the gauge usually used for both roof and sides, although No. 28 sides are sometimes deemed heavy enough. The labor cost for fastening roof and sides is approximately $1.25 per square.

WEIGHT OF CORRUGATED SHEETS PER SQUARE

	Black			Galvanized		
Gauge.	3-in. cor.	2½-in. cor.	1¼-in. cor.	3-in. cor.	2½-in. cor.	1¼-in. cor.
20	166	167	170	183	184	187
21	152	153	156	170	170	173

27	76	76	78	93	94	96
28	69	69	71	86	87	88

Doors and Windows.—The ordinary 12-light, 10 by 12-in., single windows are ordinarily used, the price varying according to local conditions. Labor cost of setting windows is approximately $1.50 each. Plain doors, 2 ft. 8 in. by 6 ft. 8¾ in. will vary in cost according to local conditions. Labor cost of setting is approximately $1.50 each. Ordinary plain hardware used on windows and doors should not cost to exceed $2.50 per door or window.

Nails.—The quantity of nails of each size required for each class of work may be fairly accurately calculated, provided that there is no excessive waste, and the following tabulation will be found to be close enough for all ordinary purposes:

	Use:	
For each:	Pounds.	Size.
1000 shingles	4	4d
	3½	3d
1000 laths	6	3d
1000 ft. clapboarding	18	6d box nails
1000 ft. siding	20	8d
	25	10d
10 ft. partition shedding	1	10d
1000 ft. 1 by 3 flooring..........	45	10d
1000 ft. 1 by 2 flooring..........	65	10d
1000 ft. pine finish	30	8d
250 shakes	2½	5d

STANDARD STEEL WIRE NAILS

A special barbed galvanized nail is used for attaching corrugated or painted sheets to wood-frame buildings, and is driven first through a lead washer, then through the iron into the wood frame. In this work 1½ lb. of 2-in. No. 9 galvanized barbed nails are sufficient for one square; 325 lead washers, weighing 1 lb., are sufficient for about two squares.

Building Bolts.—As this item is one that is subject to great variation, depending upon the ideas of individual mill designers, it is difficult to give information that will be even approximately correct without publishing mill drawings also. Keeping in mind the fact that the scope of this article covers the stamp-mill as applied to the treatment of free-milling gold ores by amalgamation only, the building bolts for a 5-stamp mill will weigh approximately 500 lb.; a 10-stamp mill, 1000 lb.; a 20-stamp mill, 2000 lb. It is quite possible to design an excellent building in which building bolts are almost entirely done away with and it should be understood that the above information should be used for what it is worth and no more. It is a comparatively simple task to calculate the number and cost of bolts required when drawings are made and submitted by the designer.

Grading and Excavating.—This is the most difficult of all to treat in generalities, as the following factors, (*a*) cost of labor, (*b*) character of the ground, (*c*) cost of powder, fuse, and caps on the ground, (*d*) whether machine drills or hand drills are to be used, are commonly all vital as far as costs are concerned, and vary widely in each locality. The average millsite has an overburden of earth of varying thickness which can ordinarily be moved by hand-picking and shoveling with possibly a few shots to loosen it thoroughly. On ground of this nature one man can remove about 10 yards in an 8-hour day, but if it must be handled in wheelbarrows for any considerable distance, the cost will probably equal from $1.50 to $1.25 per yard. On solid rock work, however, where the rock is hard and tough and does not shatter readily, and where hand-drilling is necessary, one yard for two men per day will be as much as could be expected; especially if the rock must be bulldozed after breaking in order to get it down to pieces small enough to be shoveled by hand and hauled away in wheelbarrows. These two cases illustrate the extremes in the cost of grading, and costs covering average conditions will be somewhere between these two. A mill grade of large size has been made as cheaply as $1.50 per yard for the shooting ground where all conditions were exceptionally favorable.

Powder Required.—In one specific case shooting fairly hard rock, 3420 yards, required 750 lb. of 40% giant and 800 lb. of 60% giant for bulldozing. The fuse cost about 2c. per yard and caps 1c. per yard. When the mine-owner has carried his underground development far enough along to warrant fully his considering the purchase and construction of a mill, he will have had sufficient experience in breaking his own ground to calculate the cost of his mill grading accurately.

Retaining Walls and Foundations.—Retaining walls are not required unless the ground is of such a character that it will not stand without them. They may be built either of masonry or concrete, depending entirely upon the material available on the ground. That required for concrete walls is rock (hard, and sharply broken, absolutely free from dirt, clay, or other foreign substances), clean sharp sand, first quality portland cement, and water. Another combination sometimes used is broken rock, sand, gravel, cement, and water, and while this latter will answer for retaining walls, it is not as satisfactory for machinery foundations or mortar blocks as the first combination given.

Walls are calculated by the perch, a perch being 16½ by 1½ by 1 ft. and containing 24¾ cu. ft. To make one perch, use 2500 lb. of broken rock, 1250 lb. of sand, and 625 lb. of cement. The proportions ordinarily used are 1:2:4 for cement, sand, and broken rock, and 1:2:4:8 for cement, sand, gravel, and broken rock. Lime is sometimes used instead of cement on account of its cheapness.

but it does not give nearly as great strength or permanency as cement.

The following cost of retaining walls for a 40-stamp mill built in Arizona will give an idea of the cost of this type of construction:

	Perch.
Concentrator room wall contained	135
Battery-room wall contained	371
Total	506

Cost of the above was made up as follows:

68½ bbl. of lime cost, delivered	$157
63 cu. yd. of sand cost, delivered	50
Labor: mason 59 days, helper 161 days, cost	668
Total	$875

Cost per perch, $1.72.

(Note.—Broken rock was available on the ground without charge.)

Concrete foundations ordinarily cost from $6.50 to $7.50 per cubic yard finished, when cement costs $3.50 per barrel delivered; labor, $2.25 per yard; and boxes, $0.40 per yard. A barrel of cement weighs 400 lb., and is equivalent to 4 sacks containing 1 cu. ft. each.

A man inexperienced in concrete work should not attempt to select rock, sand, or gravel for this purpose, but should obtain the advice of some one familiar with the requirements of this work. Otherwise failure is altogether likely to follow. Not all rock is suitable, by any means, and the expenditure of care in selecting raw material will be repaid in the superior quality of the finished product.

Concrete Floors.—Concrete floors are generally made 4 in. thick and require no forms or boxes, but are made from the regular concrete mixtures already mentioned, with a thin top-dressing of a thick cement grouting to give a smooth finish. The following case will give a fair general average idea as to what may be expected for cost of concrete floors:

Floor contained 6680 sq. ft., 4 in. thick.
To make this floor were required:

76 bbl. of cement costing delivered	$406
Labor: mason 40 days, helper 80 days, costing	375
Total	$781

Average cost per 100 sq. ft., $12.

(Note.—Broken rock and sand were available on the ground without charge.)

Concrete Mortar-Blocks.—As there are many different ideas as to method of construction and proportions of material to be used, I will give three specific instances of blocks which have been built and in use for a sufficient number of years to determine their practicability. They represent what may be considered as typical cases, and will give fair average conditions between the cheaper and simpler forms of blocks and the more elaborate and expensive.

The first case to be given covers the blocks used for a 40-stamp mill, which after ten years' continuous operation have proved perfectly satisfactory. The stamps weighed 1000 lb. each when new and dropped 100 times per minute. The blocks themselves were not monolithic, but were divided, the type of construction being the usual one with battery-posts going down beside the blocks and setting on short wooden streak sills. The monolithic type of block, however, in which the mortar foundation for the stamp-mill, regardless of the number of stamps, is in one piece and flush all along the top and having the battery-posts setting in cast-iron shoes, is preferable. In the case cited, each block contained 6⅔ cu. yd. The concrete was mixed in nine batches, the first eight in the proportion of 12 cu. ft. of broken rock, 9 cu. ft. of sand, and 3 cu. ft. of cement. The ninth batch, forming the top, was slightly richer and was mixed in proportion of 12 cu. ft. of broken rock, 9 cu. ft. of sand, and 4 cu. ft. of cement. For reinforcing, old wire cable was used, it being wrapped around the mortar foundation bolts for each batch of concrete. Cost was made up as follows:

Cement, 55½ bbl., cost delivered	$296
Handling sand and stone	16
Labor: mason 8 days, helper 28½ days	115
Total	$427

Cost, each, average, $55.

(Note.—Sand and broken rock were available at the mill-site without charge.)

Had wooden blocks been used, the cost under the same circumstances would have been as follows:

Lumber, 13 M ft., cost delivered	$481
Planing and setting	200
Total	$681

Cost each, average, $85.10.

For the second case, the data following cover mortar-blocks for a 100-stamp mill, which at the present time is considered to be one of the best, if not the best, built mill in the United States, everything being built and designed with the idea of absolute permanency:

A 2-horse team at $8.50 per day hauled 1 yd. of broken rock or sand per load. A 4-horse team at $14 per day hauled 3 yd. of broken rock or sand per load. Eight loads in either case constituted a day's work. Proportions used for the concrete mixture were 1 part cement, 3.6 parts sand, 3.67 parts broken rock. The battery-blocks contained a total of 108 yd. and cost $11.82 per yard, the cost being made up as follows:

Cement	$ 5.03
Rock	1.06
Rock sand	0.67
Pit sand	0.45
Labor	1.32
Forms	2.76
Engineering and superintending	0.15
Reinforcing	0.38
Total cost per yard	$11.82

The third case covers modern South African practice, the proportions used being 22½ cu. ft. of 2-in. broken rock, 7 cu. ft. of ½-in. broken rock, 13 cu. ft. of washed sand, and 1⅛ bbl. of cement, making 1 yd. of concrete. For the last 2 ft. from the top, 1¾ bbl. of cement was used, the other proportion remaining the same.

Steam-Boiler Setting.—Every boiler manufacturer has his own designs for boiler setting and publishes a schedule of the number of red brick and fire-brick required, but the following table will answer for approximate estimates to cover the setting of single tubular boilers with half fronts:

Diameter, inches.	Length, feet.	Horse-power.	No. red brick.	No. Fire brick.
30	7	10	6,000	550
30	8	12	6,200	550
36	8	15	6,700	650
36	10	20	7,050	720
42	10	25	8,700	770
44	10	30	8,800	880
44	12	35	9,300	940
44	14	40	10,800	1020
48	14	45	12,900	1140
48	15	50	13,700	1140
54	15	60	14,200	1270
54	16	70	15,000	1270
60	16	80	21,500	1540
60	16	100	25,000	1900

In making comparisons between boilers designed for a brick setting as compared with the locomotive fire-box and the internally fired types, the latter should always be considered as requiring a covering of asbestos 2 or 3 in. thick in order to reduce the radiation losses and keep the fuel consumption down. Common red brick weigh 5 lb. each and standard fire-brick weigh 7 lb. each. A 4½-in. wall equals 7 brick per square foot of surface; a 9-in. wall equals 14; a 13-in., 20; 18-in., 26½; 21-in., 33; 27-in., 39½ brick. The weight of walls is 112 lb. per cubic foot in red-brick work and 150 lb. in fire-brick work. A cubic foot of red-brick work equals 17 9-in. straight brick, and 1 cu. ft. of silica-brick work weighs 130 lb. In making estimates on red-brick work, consider that 9 cu. ft. of sand and 3 bushels of lime will lay 1000 brick, and that 250 to 350 lb. of fire-clay or silica cement will lay 1000 fire-brick. A bricklayer will ordinarily lay from 1200 to 1500 brick per day of 8 hours.

Unforeseen Contingencies.—This is an item for which no arbitrary method of figuring can be given, but which, nevertheless, forms an essential point to be considered in making up an estimate. The unforeseen always happens, and, incidentally, invariably adds to construction costs. The estimator must make an allowance to cover the unexpected happening, according to the situation on the ground in each particular case. When mill construction commences late in the season, allowance should be made for increased cost of working in stormy weather. An early rainstorm plays havoc all around, holds up freight teams, damages material not under cover, keeps men from their work in the open, and in other ways increases costs. The matter of systematic handling of shipments and material has already been mentioned, and figures given for construction costs have been based upon the intelligent and systematic handling of all work.

By way of illustration of adverse conditions, take the case of figures given on framing mill building, $25 per M board feet. Assume that the wagon-road terminates at the bottom of a hill and that the lumber and material has to be carried up the hill to the millsite for a distance of 500 ft.; 1000 ft. of dry lumber weighs approximately 3250 lb.; one man could handle about 100 lb. by hand and carry it up a 20 degree slope at the rate of 50 ft. per minute; 20 minutes would be consumed on a round trip, and counting the time lost by resting, etc., two trips per hour would be about the average for an 8-hour day. The cost, therefore, of getting the lumber to the millsite after the teams had discharged their load would be about $6 per M ft., which is about 25% increase in the total amount allowed for framing and erecting; and if such a condition as outlined should exist, 25% would have to be added to the estimated total cost of framing to cover this contingency. The same condition would obtain should the situation on the ground prevent the machinery from being hauled any closer to the millsite, and, as the figures given do not cover any such unusual contingency, it is obvious that a careful study of local conditions must be made in each individual case to arrive at a reasonably close estimate as to what the extra cost will be to cover the handling of the material on the ground as an item separate and apart from the cost of construction and erection.

On small mills up to 20 stamps in size, the amount of material to be handled would hardly justify the purchase of an elaborate outfit of construction tools and apparatus, such as power-operated derricks. Therefore appliances for lifting machinery and building material in general would consist of the usual block and tackle, gin pole, a good hand-winch, chain-block, timber dollies, and rollers. Everything would have to be man-handled from the time it is dumped off the teamster's wagon to the time when the mill is ready to start operating.*

SUMMARY

In summing up what has been written it will be noted that the greater part of the statements made are qualified by exceptions, and in fact that the exceptions seem to predominate. It is a physical impossibility to do any more than approximate labor costs when discussing conditions governing mill construction in a general way, and the best advice that could possibly be given to a man who is contemplating the construction of a mill and who has not made a profession of such work himself, is to hire a man who has. Get the best man that it is possible to obtain; get his references and then run them down thoroughly; satisfy yourself that he is honest, competent, and reliable; put him in charge, and give him your hearty co-operation and support. Do not try to induce him to work for you for less than his regular wage—you may succeed in doing this if the man has been out of work for a long time and is in need of money, and you may think that you have achieved a saving by doing so. But you will lose his respect and miss entirely the spirit of enthusiasm with which a man who has been fairly treated will use his best initiative and apply all of his energies toward the solution of the various problems and difficulties that are of daily occurrence in work of this kind.

---

*A convenient portable saw-horse that can be used under some conditions was described by Corey C. Brayton in the *Mining and Scientific Press*, August 6, 1910.

The Tertiary Gravels of the Sierra Nevada of California

By WALDEMAR LINDGREN

*Studies by the United States Geological Survey on the Tertiary placer deposits of the Sierra Nevada, California, began in 1886 and were concluded about fifteen years later. During this period topographic surveys of 22 quadrangles have been made and 14 of the quadrangles were mapped geologically. The Tertiary history of the Sierra, especially the development of the broad monocline recorded on its summits, is of great interest. A basement of closely folded Paleozoic and Mesozoic sediments was intruded and elevated near the close of the Mesozoic by granitic magmas, followed closely by the introduction of veins and seams of gold-bearing quartz. The resulting highland was planed down by erosion in early Cretaceous times. When reduced to gentle outlines deep rock decay took place and much gold was freed from its matrix. Renewed uplift quickened erosion, which concentrated the loosened gold along definite channels. During this period of most active gold concentration faulting movements with downthrow on the east side, had transformed an approximately symmetrical range to a monoclinal one with steep easterly slope.

Toward the end of Tertiary time long quiescent volcanic forces asserted themselves. Rhyolite flows filled the valleys, covered the auriferous gravels, and outlined new stream courses in the old valleys. Renewed disturbance began along the scarcely healed eastern breaks, resulting in a westward tilting of the main blocks. This encouraged deeper cutting by the streams which repeatedly crossed their old courses, and concentration of gold proceeded under less favorable torrential conditions. Volcanoes sent forth immense volumes of tuff, filling many of the valleys to their rims and converting almost the whole of the northern Sierra into a desolate, steaming expanse of volcanic mud. Storm-waters now began the canyon-cutting epoch, amazing in its results as we see them today. In many places the old rivers of the Tertiary were exposed, and cross-sections of their valleys are now seen on the steep canyon slopes high above the present river beds; but large stretches of the old channels remained secure below their blanket of a thousand feet of hardened volcanic mud.

An army of gold-seekers invaded the mountains in 1849. They worked first along the present streams, but gradually the metal was traced to the old Tertiary river beds on the summits of the ridges, and to the quartz veins, the primary sources of all gold in the Sierra Nevada. Millions of dollars were produced annually up to the seventies of the last century, but since, owing to the prohibition of hydraulic mining and the gradual exhaustion of the richer channels suitable for drift mining, the industry has slowly diminished, until now less than $1,000,000 is produced annually. Gold still exists in the Tertiary channels, much of which is yet unworked, but the problems now are to extract it without damage to other property from the débris and to reduce the cost of drift mining so as to permit the exploitation of the less remunerative deep gravels. To compensate for this decrease a new industry, that of dredging, has been developed along the bottom lands flanking the range, and from this during 1910, gold valued at $7,550,000 was recovered.

Manufacture of Superphosphate in Western Australia

By M. W. von Bernewitz

The addition of a small amount of superphosphate to the wheat and other lands of Australia shows a marked response in increased yields, even when the season is somewhat dry. For many years it was thought that there was no great area in Western Australia suitable for wheat, because of the poorness of the soil and the lack of rain. That this idea has been exploded is shown by the fact that, in 1901, 74,308 acres produced 774,653 bushels of wheat, and in 1910 580,568 acres yielded 5,885,877 bushels, and 69,265 acres of oats produced 1,121,865 bushels. This has been brought about by scientific farming, and the use of superphosphates. These areas have an annual rainfall of from 10 to 18 in. The use of from 30 to 100 lb. per acre of superphosphate has made it possible to grow wheat upon the border of the eastern goldfields, where there is only 10 to 14 in. of rain yearly, with high yields. At one time our wheat and flour was imported from the eastern States; but now steamers call at Fremantle and are loaded by mechanical elevators and conveyors, and Western Australian wheat is exported throughout the world.

MT. LYELL SUPERPHOSPHATE WORKS.

Superphosphates have been made in Australia for many years, the first works being built near Melbourne, in Victoria. About eight years ago, the Mt. Lyell Mining & Railway Co., of Tasmania, decided to enter the field of manufacturing superphosphate, and erected its first unit at Yarraville, near Melbourne, with great success. F. J. Howell was appointed to advise the company on agricultural matters. Later on, works were erected at Port Adelaide, in South Australia, to supply the farmers of that section, and, two years ago, recognizing the future possibilities of Western Australia as an agricultural country, works costing $450,000 were built at Fremantle. All these plants can produce 100,000 tons of superphosphate yearly. About 265,000 tons is annually used in Australia.

Last January I visited the Fremantle works, and was afforded every facility for noting the process of manufacture by the works manager, A. D. Ferguson. This was the busy time of the year, preparing for the next crop. The plant is situated high up in Rocky bay, on the Swan river, two miles out of Fremantle, being connected by rail with the port, and all other lines to the farming districts. Being used to following the treatment of an ore in a mill, one process after another to the end, it impressed me that in the Mt. Lyell plant the raw materials entered at opposite ends and the treatment was completed in the middle, as it were.

The whole plant is driven by motors, from power generated in the company's own power-house, which comprises the following: Two Babcock & Wilcox boilers fitted with chain grate stokers, fed by an automatic coal-handling plant; superheaters, economizers, and induced draft by a Sirocco fan; boilers fed by a motor-driven pump, with a steam pump as a stand-by, the water being measured by a meter, while a CO_2 recorder keeps a check on the firing. The generating plant consists of two Allen engines of 220 and 250 hp., running at 128 r.p.m., direct connected to Swedish General Electric generators of 180 and 270 amp., 460 v., 50 cycles, respectively, each having an overhung exciter. Steam is condensed by a Relly & Lewis (Melbourne) condenser, with a motor-driven pump. The switchboard is equipped with the usual voltmeters, ammeters, and voltage regulator. The railway workshops nearby are supplied with power from the Mt. Lyell company.

Pyrite, for acid making, comes from the Mt. Lyell mine, on the company's leases at Chester, in Tasmania, and contains 45 to 50% sulphur. From the railroad cars it is tipped onto an 18-in. belt-conveyor which elevates it to the private storage building, which has a capacity of 8000 tons. This building is constructed of steel and corrugated iron, and is shown in the illustration. From the pile, the pyrite is shoveled upon a short belt which feeds a jaw-breaker. The crushed mineral is elevated to a revolving screen, the oversize passing to a pair of rolls; the product from this machine is also screened, all oversize being returned to the rolls, while the final product, about $^3/_8$ in., is elevated to a storage bin. From this it is taken by a push-conveyor to the eight Herreshoff mechanical roasters. These are automatically fed from a small hopper by a push feeder.

CRUSHING DEPARTMENT.

There are three hearths in each furnace, and four rabbles on each, with shoes set at different angles, each set cutting diagonally across the track of the preceding one. The rabbles are fixed to a central gear-driven spindle. The furnaces roast about three tons each daily, the discharged pyrite averaging 2 to 3% sulphur. No fuel is used once a furnace is hot, the sulphur in the ore being sufficient to keep the charge burning. The residue is wheeled out to a dump. The sulphur fume is drawn by a fan through a lead pipe, 30 in. diameter, to the acid chambers. These consist of 6 chambers with the necessary Glover, Gay-Lussac, and contact towers. Automatic lifts are used for pumping acid over the tower, the acid to the superphosphate milling plant flowing by gravitation. The acid building is 240 ft. long by 88 ft. wide by 56 ft. high, and has a capacity of 15,000 tons of H_2SO_4 annually.

The phosphate rock, which comes from Christmas island in the Indian Ocean, comes in at the far end of the works, and is fed into a large jaw-breaker, and by belt-conveyor fed into a smaller breaker and crushed to about 1-in. size. This is elevated to a hopper above the ball-mill. This is a No. 8 Humboldt type, and is fed by a shaking feeder worked by cams. The rock is crushed through 16-mesh screen, and is elevated to a bin. From here a certain amount is automatically weighed and run into a revolving mixer with the requisite quantity of sulphuric acid. When mixed the pulp is run into a car below, which is pulled to the end of the plant by a wire rope and discharged upon a floor below. Here it dries, and is then elevated, bagged, weighed, and stacked in cars for shipment to the farming districts of Western Australia.

Slime Filtration

By George J. Young

*Much has been written concerning an accurate definition of the term 'slime,' but no comprehensive definition seems to be generally accepted. An excellent study of the nature of slime, by R. E. Ashley, was published in the *Mining and Scientific Press* of June 12, 1909. The accepted present practice in milling work is that all material in a pulp finer than a 200-mesh screen is considered as slime. The definition that a slime is the unleachable portion of a mill-pulp is also in use. A more comprehensive definition than the foregoing is that a slime consists of a mixture of sand finer than 150 or 200-mesh screen with an amorphous clay-like material, consisting principally of hydrated aluminum silicate.

The general method of slime-treatment is to agitate the slime with a cyanide solution for a sufficient time to dissolve the gold, and then, either to filter off the surplus solution and displace the remainder with water, or to thicken the slime by settlement and decantation, and then to filter and displace the remaining solution by water. The mechanical appliances in use for filtration are grouped as follows:

These filters are continuous in action.

I. Suction-filters, or filters in which a vacuum is used to accelerate filtration.

A. Appliances using a thin slime-cake and practically continuous in their action. (Oliver and Ridgway filters.)

B. Appliances using a thick slime-cake and intermittent in their action. (Moore and Butters filters.)

II. Pressure-filters, or filters in which hydrostatic head, compressed air, or pumps are used in order to secure greater pressures than are possible with a vacuum-pump.

These filters are intermittent in their action.

C. Ordinary filter-presses.

D. Sluicing filter-presses (Merrill filter-press).

E. Filtering-chambers or cylinders; filters in which the filtering-basket is enclosed in a cylinder. (Burt, Kelley, and Sweetland filter-presses.)

III. Centrifugal filters, or filters in which centrifugal force is used to separate solution from slime.

The filters in sections I and II, with the exception of the Ridgway, employ vertical filtering-surfaces. The Oliver makes use of a revolving cylindrical surface as a filtering surface. Centrifugal filters are in process of development and have not as yet secured any foothold in gold and silver metallurgy. It is not improbable, however, that some comparatively simple filter based on the use of centrifugal force will be perfected, and will successfully compete with the other forms. At present the suction filters are in greatest use. Of the pressure-filters, the ordinary filter-presses have gone out of use, except as clarifying presses, and filters of groups *D* and *E* only are in use.

The development of slime-filtration is of interest. Filter-presses and filtering-beds in vats were first used. The filtering-beds were soon discarded and the filter-press systematically developed. The size of the press was increased, mechanical devices to facilitate discharge and decrease the proportion of labor required were invented and introduced; but in spite of all this the cost of treatment in filter-presses remained high. In western America the filter-press never received much recognition, but in Australia filter-pressing was extensively introduced, and slime was successfully handled by this method. It remained for an American, Charles W. Merrill, to complete the last improvement in the filter-press. By the introduction of the sluicing system the slime-cakes can be washed out of the filter-cells and the press operated without opening or separating the filter-plates for each charge. This improvement reduced the labor and cost, and increased the effectiveness of the filter-press. The Merrill press represents the culminating point in the filter-press line of development in slime filtration.

The Moore filter was the first suction-filter in the field, and introduced the idea of the canvas-covered filtering-cell immersed in the slime-pulp and utilizing suction to draw the solution through the walls of the cell and to build up a cake. The necessary transfers are made by lifting the filtering-basket out of the pulp. The Butters filter introduced the idea of a stationary filtering cell, and effected the transfers by pumping the slime-pulp and wash-water from the vat in which the filtering-cells were immersed. The relative merits of the two systems have been sufficiently discussed in the technical literature. Both the Moore and the Butters filters have reached a point where little or no further improvement seems possible. Like the Merrill, either one of these systems will satisfactorily meet the requirements of slime-filtration. The combination of the ideas involved in the filter-press and the suction filter is seen in group *E*, or the filtering-chambers. The Kelley, the Burt, and the Sweetland may be compared to a Butters filter installed in a pressure-tank.

The effort to secure a continuously-acting filter has resulted in two important types being developed, of which the Ridgway and the Oliver are the best known. Both of these filters utilize a comparatively thin slime-cake. Both operate very successfully, and compared with the thick-cake machines have decided advantages, briefly stated as simplicity of design; probably lower capitalization-charges for equal capacities; lower operating costs; and less attention required in the operation.

With the exception of the Oliver filter, the general method of operation of both suction and pressure-filters is the same. The slime-pulp is delivered to the filter in the proportion of one of dry slime to from three to one of solution. The pulp is forced into the cells of the pressure-filters and a cake formed against the canvas walls of the cells, the surplus pulp, if any, is withdrawn, and wash-water forced in until the contained solutions are displaced. The cake is then forced off from the canvas surface, either by water or air, or a combination of both, and sluiced out. In the vacuum-filter the filtering-cells are immersed in the pulp, a vacuum is formed, and a cake built up; the surplus pulp is then withdrawn either by lifting the filtering-cells out or by withdrawing the pulp by pumps, and the cakes are immersed in water for washing. In the Moore filter the cakes are discharged by forcing them off from the cell by water or air and dropping into a hopper for sluicing away; in the Butters the cake is forced off in the same way, but while still immersed in the wash-solution. The wash-solution is then withdrawn, either by decanting or pumping, and the slime-cake and surplus wash sluiced out. The Oliver filter performs the operations of cake-formation, washing, and discharge in continuous sequence. Three steps may be designated as common to all these filters: cake-formation, washing, and discharge. The cycle of operations of the more common forms of filters is shown in the accompanying figure. Typical examples have been taken in each case.

The condition under which slime-cakes are formed and washed are the critical points to be considered; the discharge and sluicing away of the cake is a comparatively simple matter and requires no special comment. My experimental work was largely confined to suction-filtration, and pressure-filtration was only briefly studied. Experiments on the variation of the filtering rate with variable thickness of slime-cake both while building up and in clear water, indicate that the filtering rate during building up a cake is greater in the pulp then in clear water for thin cakes, while for the thicker cakes the reverse is true. The general effect of increase of pressure upon the filtering rates of cakes of varying thickness is to increase the filtering rate. This is more marked with the thin cakes, while with thick cakes the effect of an increase of pressure is to increase the density of the cake and thus reduce its permeability. With higher pressures this effect is more marked, and indicates that a point would soon be reached where the increased pressure would result in decreased filtering rate. This is particularly true of slime containing a small proportion of sand, and much less so with slime containing a large proportion of sand. In the use of both the Moore and Butters systems, experiments should be made with different intensities of vacuum, for it may be found that a vacuum lower than the maximum obtainable with the available apparatus will give a higher filtration rate, and thus decrease the time for both building up and washing. Many experiments were made upon the effect of temperature on filtration, the character of the slime-cake, the effect of the character of the filtering surface and the method of its support, the rate of building up the cakes, and washing the cake. For details of these experiments and the curves showing the results attained, reference should be made to the original paper.

DETAILS OF FILTER PLANTS.

Data were secured from a number of slime-plants in Nevada through the courtesy of the different managers. The table shows the results of a number of physical analyses of slimes obtained from these plants. For purposes of comparison the type slime, the sand-slime mixture, the clay slime, and the filtering rates are included. The lower table gives the data of the slime-plants from which the mill-slimes in the upper table were taken.

The practical conclusions which may be drawn from the experimental work may be summarized as follows: 1. The proportion of clayey material in ores which are to be subjected to 'all-sliming' and filtration should be maintained at a minimum. 2. The slime-pulp should be as free as possible from sand coarser than 150-mesh, and as large a proportion of the pulp as possible should consist of material passing 200-mesh. 3. The slime-pulp before filtration should be settled as thick as possible consistent with ready handling by pumps and in pipes. 4. The temperature of the slime-pulp should be maintained between 20 and 30°C., or higher. 5. The temperature of the wash-water and the pulp should be the same. 6. Vacuum-pressures should be varied until the proper intensity for the given slime is obtained. 7. Where the very clayey slime is to be filtered, as much fine sand should be crowded into the pulp as it will carry without undue settling and clogging. 8. No. 10 canvas supported by slats gives the best all-round service for the thick cake, and No. 12 canvas on wire netting answers the requirements for the thin-cake filtering machines. 9. With slime containing a large proportion of colloid or clayey material pressures greater than those obtainable with vacuum apparatus are of questionable advantage. 10. With slime containing a large proportion of clayey material the vacuum-filters should be used. 11. With slime containing a small proportion of clayey material and much fine sand both vacuum-filters and pressure-filters could be used with perhaps equally good results. 12. With slime containing much coarse and fine sand the chamber-filters with air-agitation and high pressure would perhaps give the best results. 13. Of the vacuum-filters, the thin-cake continuous filters are a decided improvement over the thick-cake filters.

Pure sulphur is obtained directly from wells in Louisiana by the Frasch process. A well is driven in much the same manner as a gas or oil well is sunk, and into it are placed several concentric lines of pipe. Superheated water, introduced through the outer pipe, melts the sulphur, which may be several feet below the surface. Hot compressed air is then forced through the smallest of the pipes. This forms an aerated emulsion with the molten sulphur, which is forced out by hydrostatic pressure between the remaining pipes and discharged in a purified form into large vats, where cooling, solidification and feeding go on simultaneously.

Metal Production of Idaho, 1910

The value of the mine output of gold, silver, copper, lead, and zinc in Idaho in 1910, according to C. N. Gerry, of the United States Geological Survey, was $16,316,196, against $15,660,849 in 1909, an increase of $655,347. There was a decided decrease in the yield of gold from both placer and lode mining, also in the production of copper. The largest increases in production were in lead, in silver from lead ores, and in zinc. Shoshone county mines yielded 88% of the value of the State's total output of the metals.

The total production of gold was $1,096,842, a decrease of $356,980 compared with 1909. Of the gold output, $242,546 was derived from placers, of which Boise county produced $129,663 and Nez Perce county $40,699. Of the gold from lode mines, about 10% was derived from copper, lead, and zinc ore and 90% from silicious ore. From bullion in gold and silver mills 32,626.21 oz. was recovered; concentrate produced 5936.67 oz., and crude ore shipped to smelters contained 2763.69 oz. The largest producer of gold was Owyhee county, which yielded $388,728, against $425,305 in 1909. Boise county produced $199,430 in 1910, against $216,031 in 1909, a decrease of $16,601, occasioned almost entirely by a lessened output from placer mining.

The silver production of Idaho in 1910 was 7,369,742 oz., valued at $3,979,661, against 7,041,633 oz., valued at $3,661,649, in 1909. Of the 1910 output, 6,479,636 oz. came from lead ore. Bullion at gold and silver mills produced 315,356 oz., concentrate gave 4,463,517 oz., and crude ore sent to smelters contained 2,588,431 oz. Shoshone county (in the Coeur d'Alene) produced 6,703,080 oz., or nearly 91% of the silver output of the State. Of this, the Hunter district produced 1,208,958 oz., the Lelande district 2,822,789 oz., and the Yreka district 2,629,802 ounces.

The production of copper in Idaho decreased from 9,115,489 lb., valued at $1,185,0[illegible]4, in 1909 to 7,037,292 lb., valued at $893,736, in 1910, but the production of Custer county increased from 90,461 lb. to 919,648, as a result of the operations of the White Knob mine. True copper ore yielded 5,912,392 lb., and nearly all the remainder was derived from the lead ores of Shoshone county.

The output of lead in Idaho in 1910 increased 12,272,554 lb. over that of 1909. The value of the lead produced in 1910 was 61.5% of the value of the total metal production. Crude ore shipped to smelters contained 50,084,367 lb., and concentrate (of which all but 704,652 lb. came from Shoshone county) yielded 178,174,472 lb. The production of Blaine county decreased 477,302 lb., while Lemhi county showed an increased yield of 6,394,403 lb., or nearly half of the State's increase, owing to the completion of the Gilmore & Pittsburg railroad from Armstead, Montana, to Salmon, Idaho. The Yreka district, with a yield of 109,899,539 lb., was much the largest producer in Shoshone county and in the State. The lead output of the Hunter district was 34,319,319 lb., and that of the Lelande district 72,840,963 pounds.

The zinc production of Idaho was 4,252,104 lb. greater in 1910 than in 1909. With the exception of a small quantity of zinc produced in Blaine county the output was derived from concentrate shipped from the Success mine, in Shoshone county. There were 417 mines producing gold, silver, copper, lead, and zinc in Idaho in 1910, compared with 324 in 1909. Of these 417 producing mines, 262 were placer mines, many of which made small outputs. The total quantity of ore treated or sold in Idaho in 1910 was 1,786,174 short tons having an average value per ton of $8.99, an increase of 13,791 tons and of $0.31 per ton over 1909.

MINE PRODUCTION OF GOLD, SILVER, COPPER, LEAD, AND ZINC IN IDAHO IN 1910, BY COUNTIES.

*Includes placer production.

COPPER PRODUCTION was reported from 23 counties in Colorado in 1910, and of these Lake, San Juan, Ouray, Cleark Creek, San Miguel, Gilpin, Hinsdale, Chaffee, and Eagle counties, in the order named, were the most important producers, Lake county alone furnishing 43.6% of the total output, San Juan county 14.5%, and the 9 counties combined 96%. Copper mining in Colorado is of secondary importance compared with that of gold, silver, lead, and zinc, but is of considerable importance in bringing the mixed ores of the State to a total value commercially profitable.

L. VOGELSTEIN & CO. give the following figures of German consumption of foreign copper for the months January to August 1911:

	Tons.
Imports of copper	125,298
Exports of copper	5,793
Consumption of copper	119,505

as compared with consumption during the same period in 1910 of 108,876 tons. Of the above quantity 109,441 tons was imported from the United States.

The Marketing of Copper

The marketing of copper is an important step in the production of that metal, and the following taken from *The Boston News Bureau*, will interest our readers. The past year did not witness any important changes in the copper selling industry. Today the refining and selling of the metal is controlled by less than a dozen interests. Excluding foreign ores, the agencies of this country have for some time past been marketing in the aggregate more than 1,000,000,000 lb. of copper per annum, representing on present market a gross value of $122,000,000. The selling contracts are not uniform. Rates of commission on sales vary from 1 to 1½%. Many of the companies which sell their output direct to the trade frequently give the buyer the advantage of an amount equal to what an agent or broker would receive were the transaction handled by a third party.

The United Metals Selling Co., now owned by the Amalgamated Copper Co., has retained its position as the largest individual seller of copper in the world. The margin between this agency and its nearest competitor, the American Smelting & Refining Co., has, however, lessened considerably during the past few years, or since the Guggenheim properties withdrew from the United Metals company some of their output. The Guggenheim interests were fortunate in securing during the year two new contracts for treating and selling the product of the Ray and Chino copper companies. This agency will likewise handle the output from the Braden Copper Co. The output from the Utah Copper Co. will be increased this year to 100,000,000 lb. and next year by an additional 25,000,000 to 30,000,000 lb. Ray should produce next year 50,000,000 and Chino 30,000,000 lb., but not all of this may be in marketable form during the calendar twelve months.

Adolph Lewisohn, who headed the United Metals Selling Co. until its recent absorption by the Amalgamated Copper Co., has again become a factor in the selling of copper, as he will take charge of the Miami Copper Co. product. By shut-downs of various properties during the year the American Metal Co. lost heavily. The Imperial Copper Co. ceased operations months ago, eliminating 10,000,000 lb. annually from this agency's tonnage. A few weeks ago Granby was forced to close its smelter by reason of fuel shortage which will 'cost' the American Metal Co. another 10,000,000 lb. for the balance of the year. The Phelps-Dodge agency, in addition to marketing its own product, has also been selling the output of new Calumet & Arizona Co. Much of the falling off in amount to be sold through this agency is accounted for through cessation of shipments by the Shattuck-Arizona property, the product from which was treated at the Copper Queen smelter. In 1910, 14,751,000 lb. was produced by this company, and until smelter shipments stopped last June, 4,111,000 lb. had been brought to market in 1911.

The United Metals lost one contract—that of the Tennessee Copper Co.—and this loss was the Guggenheim's gain, for a new contract was entered into with the American Smelting & Refining Co. Commencement of operations by the Electrolytic Refining Co. of Australia caused some little readjustment in contracts relating to the producers of Australia, most of whom sent their copper to United States refiners for treatment and sale. The new refinery is owned and operated by the Aron Hirsch & Sohn—L. Vogelstein & Co. interests. One of the losers through the opening of this plant was Beer, Sondheimer & Co., a German concern which for several years has maintained a New York office. The firm has never become a large factor in the copper trade, however. It formerly imported the product of the Mt. Lyell company from Australia and sold it to refiners here, but this has ceased. The firm did, however, secure a contract for selling the British Columbia Copper Co.'s output and the refining contract went to the International Smelting & Refining Co. This firm also imports the Cuba Copper Co. product, but sells the ores to a refinery.

The action of the International Smelting & Refining Co. in agreeing to refine the British Columbia output when its agency, the United Metals, did not secure the selling contract, has caused much comment and criticism among the other selling interests, on the ground that each refinery should sell all the copper it makes and thereby obviate the possibility of some of its own product being met in the market in competition. Another such instance was the acceptance by the International company of the South Utah Mines & Smelters contract when E. P. Earle secured selling of the copper. Mr. Earle has added considerably to his copper sales during the year by importing Japanese copper, which he refines and then sells to the trade.

Japanese importations are distributed among the various refineries, which sell the refined product. Spain has been sending considerable Rio Tinto copper for treatment, while South African mines have been shipping copper to the A. S. & R. plant at Perth Amboy. Other foreign countries have been adding largely to the imported tonnage, and these imports have to some extent neutralized the effects of curtailment among the American copper mines. Based on present production the volume of copper which each of the selling agencies in the United States will handle in 1911 will be approximately as follows:

United Metals Selling Company

	Pounds.
Amalgamated and North Butte (includes smelter product)	264,000,000
Lake mines (Copper Range and Calumet & Hecla sudsid.)	90,200,000
Arizona Copper Co.	34,000,000
Utah Consolidated Mining Co.	8,000,000
Greene-Cananea	46,000,000
Pennsylvania Salt Mfg. Co.	5,000,000
Total	447,200,000

American Smelting & Refining Company

Cerro de Pasco	48,000,000
Tacoma refinery and smelter products (includes Alaskan Copper)	*100,000,000
Utah Copper Co.	100,000,000
Nevada Consolidated	65,000,000
First National Copper Co. (closed July 1)	5,000,000
Tennessee Copper Co.	14,000,000
Ray Consolidated	10,000,000
Total	342,000,000

*Includes miscellaneous imports and Ohio Copper Co. output.

Phelps, Dodge & Company

Copper Queen smelter	112,000,000
Detroit Copper Co.	23,000,000
Calumet & Arizona	48,000,000
Total	183,000,000

American Metal Company

Old Dominion Copper Co.		27,000,000
Shannon Copper Co.		14,000,000
Great Fitzroy (imported)	6,000,000	
Granby	10,500,000	
Smelter and misc., inc. Ducktown	45,000,000	61,500,000
East Butte		10,000,000
Teziutlan Copper Co.		12,000,000
Torreon smelter		6,000,000
Total		130,500,000

L. Vogelstein & Company

United States S. R. & M. Co.	24,000,000
Matte, smelter material, and imports	40,000,000
Orford Copper Co.	20,000,000
Consolidated Arizona	6,000,000
United Verde Copper Co.	40,000,000
Total	130,000,000

E. P. EARLE

South Utah Mines & Smelters	4,000,000
Japan imports	5,000,000
Total	9,000,000

BEER, SONDHEIMER & COMPANY

British Columbia Copper Co.	7,200,000

W. PARSONS TODD

Winona Copper Co.	1,800,000

[illegible]

Calumet & Hecla	70,000,000
Ahmeek	4,000,000
Superior	3,000,000
La Salle	245,000
Victoria	1,000,000
Total	78,245,000

DIRECT TO TRADE

[illegible] Copper Co.		6,000,000
Quincy Mining Co.		22,500,000
Smelting plants:		
Wolverine	9,500,000	
Mohawk	12,000,000	21,500,000
Franklin		2,200,000
Mass		1,400,000
Centennial		1,500,000
Miscellaneous		60,000,000
Total		114,100,000

While over 300,000,000 lb. of copper produced outside the United States comes to this country for refining and sale, over 200,000,000 lb. of foreign production is sold for the most part in Europe and by no way figures in American statistics. The largest of foreign producers, Rio Tinto, markets its own output. A small portion of this production finds its way to the United States. Of foreign production 265,000,000 lb. annually is sold as follows:

Mine	Production (lb.)	How Sold.
Cape Copper	18,000,000	Direct
Great Cobar	14,000,000	Merton & Co.
Mansfeld	40,000,000	Direct
Mason & Barry	7,000,000	Sells ores
Rio Tinto	75,000,000	Direct
Spassky	7,000,000	"
Tharsis	4,000,000	"
Wallaroo & Moonta	11,000,000	Aron Hirsch & Sohn
Mt. Lyell	17,000,000	"
Boleo	24,000,000	Direct
Mt. Elliott	12,000,000	Brandeis Goldschmidt
Chillagoe	5,000,000	H. R. Merton
Total	265,000,000	

The unrefined copper below goes to America to be refined and sold:

	Pounds		Pounds
[illegible]	45,000,000	[illegible]	100,000,000
Rio Tinto	25,000,000	Japanese mines	25,000,000
British Columbia	8,000,000	Chilean mines	15,000,000
Great Cobar	4,000,000	Miscellaneous	10,000,000
Mt. Lyell	4,000,000		
Greene-Cananea	50,000,000	Total	291,000,000

The year's imports should reach [illegible] lb., as follows:

	Pounds
Pig copper	270,000,000
Ores and matte	90,000,000
Total	360,000,000

The production of manganese ore in the Nikopol district, South Russia, [illegible] pounds [illegible] the first half of 1910, a decrease of [illegible] pounds. The quantity [illegible] pounds, [illegible] pounds in 1910. The difference, [illegible] pounds, was taken from reserve.

Eucalyptus Oil for Mineral Flotation

In the course of experiments conducted at the Central mine, Broken Hill, New South Wales, on the separation of sulphides by flotation, Henry Lavers, metallurgist for the Minerals Separation Ltd., discovered that eucalyptus oil gave the best results, only 6c. worth per ton being required to effect the desired separation. Further experiments have shown that flotation processes employing eucalyptus oil may be used for the separation of a variety of sulphide minerals, so that the supply of this oil becomes a matter of interest. Practically all the eucalyptus oil now consumed in the United States is employed for medicinal purposes, selling for about 35c. per pound. Nearly all of this is imported from Australia, small amounts being produced in California. The most important factor in the production of the oil is the cost of collecting the leaves, and the difficulty of securing a sufficient supply of labor for this purpose. It has been suggested that machinery be employed for the work, and that larger stills be used for the distillation. H. G. Smith was appointed by the Minister of Public Instruction and Labor to investigate the eucalyptus-oil industry of Victoria, South Australia, and New South Wales, and the following is taken from his report.

"The demand for eucalyptus oil for mineral separation is likely to increase, particularly if it can be cheapened so as to prevent competition from other sources. By working in a large way and collecting the leaves by machinery, the cost of the oil should be much less than at the present time. The required species must be concentrated over a considerable area—in fact, some form of cultivation and preparation is needed. If this were done the price of the oil would be reduced considerably. Some form of Government control is needed, and areas for eucalyptus oil distillation granted to manufacturers, as is done in Victoria. Without this security, it is hardly likely that people will embark capital to further the industry. It is not probable that the crude 400-gal. tank method will be readily superseded, because it provides a living for individual families; nor is it desirable that such individual effort should be discouraged, but the force of competition will eventually render such effort unremunerative as at present carried out. By some system of coöperation any ill effects in this direction might be obviated, a party working a specific area together, as in the old mining days. The high lands of the Dividing Range, starting from, say, Crookwell to the Victorian border, where the peppermint species grow so plentifully, might well be set apart for eucalyptus oil distillation (Crown lands), as this country is of little use for agricultural purposes. By planting in this area species like *E. amygdalina*, *E. dives*, etc., considerable employment might be found in the industry, and, under systematic control, become of some importance. The success of eucalyptus oil in foreign countries will depend entirely on its cheapness, because local demands will be met by the distillation of local material, which, though not so good for the purpose, yet would answer fairly well if eucalyptus oil were too dear."

A small amount of eucalyptus oil is now being produced in California, and in the event of the development of a market for the crude oil it is not improbable that the local output could be greatly increased.

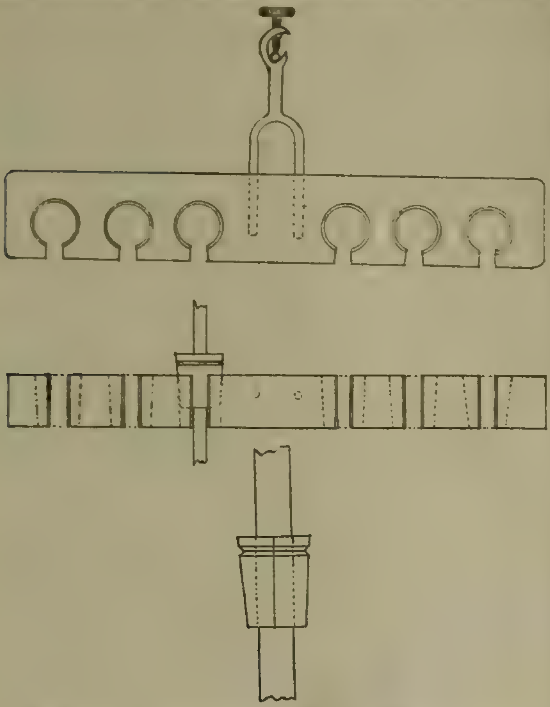
The Mount Bischoff Tin Mining Co. does not distribute its report broadcast, because it is still a close corporation, with a capital represented by the original expenditure and not watered for Stock Exchange purposes. This company is also suffering from scarcity of labor, so much so that it has been impossible to proceed with the erection of the additional treatment-plant, while prospecting and development work has been suspended. The report for the first six months of the year shows that 15,641 tons of ore yielded 156 tons of tin concentrate. The total yield was identical with that of the previous half-year, but the yield per ton was rather higher. In addition to this production, the smelter at Launceston treated 1041 tons of custom ore. The dividend absorbed £22,500.

A Handy Burette Holder

By N. Roberts and F. A. McDermott

Being obliged, on an occasion three years ago, to work with a small traveling outfit forty miles from a base of supplies, it became necessary to improvise a compact support for a considerable number of burettes. The resulting device was more satisfactory than the conventional article, and is now in constant use.

A piece of board of suitable size (50 by 8 by 2.2 cm.) is bored, a little in front of the middle, with a row of holes about 2.5 cm. in diameter and 5 cm. between centres. These holes are then connected with the front of the board by saw-cut slots about 1.7 cm. wide. All edges are rounded and sandpapered, the bored holes being filed out so as to be slightly conical, with the base up. Conical corks are then selected to fit the holes so that about 1.5 cm. of the upper end of the cork will project when snugly pushed down. The corks are bored with borers slightly smaller than the burettes they are to carry, and then split longitudinally with a knife into two equal parts. When the two halves of the cork are placed around a burette and wedged snugly down into a hole in the board, the burette will be held securely, but at the same time may be slid up and down much more easily than if held in rubber. There are no screws to rust or strip, and the burette is much easier to insert and remove (through the slot) than in a screw clamp. The burettes being held in a regular row at the most convenient intervals, a single stand will hold many more than is convenient with screw clamps. The arrangement may be further improved by cutting a shallow groove around the cork, before splitting, about 0.5 cm. from its larger end; in this groove are placed two or three light rubber bands. This arrangement adds to the ease of operation, as the cork is held on until deliberately removed and yet permits the burette to slip up and down easily; one also does not have to be so careful in placing the cork in the slots as when the bands are not used. The perforated board is supported by some form of bracket; we use a metal clamp sliding on an ordinary vertical support with a heavy base. A burner fork makes a convenient bracket, it being only necessary to bore two holes horizontally into the back edge of the perforated board at the proper distance apart to receive the prongs of the fork. The support may also be used with small funnels, and a similar device with larger holes for larger funnels. The slot in the front makes it possible to easily remove the funnel from the support without loss while it is still dripping rapidly, the stem of the funnel passing out through the slot while its lower end is kept in the receiving vessel.—*Jour. Amer. Chem. Society.*



SKETCH OF A CONVENIENT FORM OF BURETTE HOLDER.

Goldfield Consolidated Report

During the month of September, according to the report of J. F. Thorn, general superintendent of the Goldfield Consolidated, the total production was 26,760 tons, containing $676,383, or an average of $25.28 per ton, of which 26,679 tons was milled with an average extraction of 94.11%, and 81 tons of an average value of $77.12 per ton was shipped; the net recovery from all ore being $23.80 per ton. The total net profit of the company was $444,366, or $16.60 per ton. During the month 3192 ft. of development work was performed. The total cost of mining, development, transportation, milling, office, and general expense was $7.28 per ton, distributed as follows:

Mining:		
Development	$0.88	
Stoping	2.34	$3.22
Transportation		0.07
Milling		2.22
Marketing		0.93
General expense		0.42
Bullion tax		0.19
Marketing ore shipped		0.05
Construction		0.18
Total cost of operation		$7.28
Miscellaneous earnings		0.08
Net cost per ton		$7.20

In the Clermont the 466-intermediate between the 600 and 750-ft. levels, and just south of the 428 and 401 stopes, has been extended 80 ft.; cross-cuts driven in two places to the hanging wall, exposing 20 ft. of ore, and a raise started near the present face. This work produced 707 tons averaging 4.77 oz. This orebody has been cut by a raise from the 483 cross-cut, 16 ft. above the 750-ft. level. The 420-H raise has broken into the 413 sill floor. It intersected the 413 ore at a point 30 ft. vertically under the sill and produced 267 tons, containing 2.93 oz., through to the sill. The 488 cross-cut into the foot-wall under 428-C stope has exposed 6 ft. of 2-oz. ore. A new stope, 408-D, southeast of the old 428, has been opened and produced 215 tons containing 1.42 oz. The Grizzly Bear shaft has been cleaned out and equipped, and sinking is now in progress.

In the Mohawk the new 150-ft. level has been completed, and provides an efficient means of working the new ore uncovered in the upper workings. No. 21 cross-cut from No. 3 drift produced 103 tons, containing 1.31 oz. The new stope started from No. 13 drift produced 350 tons, containing 2.03 oz. The new sill floor on the 490 intermediate produced 101 tons containing 1.54 oz. The 490-A raise produced 309 tons of an average 1-oz. content.

At the Red Top the 101 sill, 200 ft. south of the shaft, has been considerably extended and produced 519 tons of 3.28-oz. ore. This connects with the 202 stope from the second level. The 305 drift in the Laguna was advanced and connected with the Hazel shaft. The Hazel shaft has been unwatered and repaired to a point 680 ft. deep. The low tonnage milled for the month was caused by shut-downs for the purpose of re-lining tube-mills, and repairs to Chilean mills. The foundations for the roasting plant and buildings have been practically completed, and the construction work is progressing at a satisfactory rate. Owing to the fact that all working faces in the Mohawk mine dropped below average the production was low for the past month, but the indications now point to the present month being somewhat above average.

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Technical Journalism and ——?

The Editor:

Sir—I wish to express my approval of your editorial in the issue of October 14, entitled 'Technical Journalism and ——?' I have been a subscriber and for many months an interested reader of *Mines and Methods*, and it certainly deserves credit for having induced greater publicity in the reports of prominent mining companies, but its persistent pursuit of the Utah Copper Co., and its monomaniacal harping upon the one subject, of the affairs of this company, has probably defeated the object at which *Mines and Methods* aimed, as do all vituperative publications. I, for one, have become so weary of it, that I discontinued my subscription and do not read that journal any more, because of the very reason you state, namely, that one cannot feel confidence in the statements appearing in a technical journal which is so evidently biased and prejudiced.

F. L. Sizer.

San Francisco, October 25.

Nicaragua and Its Gold Industry

The Editor:

Sir—I must express my appreciation of the charming description of Nicaragua and its advantages and disadvantages, in the story by T. Lane Carter in the *Mining and Scientific Press* of August 12, but must take issue with him on one or two points. Mr. Carter classes the laborers here as "on the whole better workers than the peons of Mexico." I am quite sure he is mistaken; in fact, in a brief description of this labor, presented at the Wilkesbarre meeting of the American Institute of Mining Engineers last June, I took the diametrically opposite point of view, and have had no reason to change my opinion since. I consider the class of labor available in Nicaragua as without doubt or exception the poorest native labor I have ever handled. The following figures are taken from our books:

Ramon Salinas, contractor, with three partners, during February drove 25 ft. in medium soft sulphide ore, breast 5 by 6 ft.; cost, $4 gold per foot, plus board, for labor alone; worked 18 shifts and laid off 38 shifts.

March, with four partners, he worked 22 shifts and laid off 40 shifts; made 38 ft.; same place, same price. Average driving for the two months 0.24 ft. per man per shift.

Juan Ruedes, contractor, and one partner, during February drove 32 ft. in soft oxidized surface porphyry, breast 4 by 6 ft.; cost $3.85 per foot, plus board, for labor alone; worked 18 shifts and laid off 38 shifts.

During March, the two drove 45 ft. in the same place and at same price, worked 29 shifts and laid off 33 shifts. Average driving for the two months, 0.6 ft. per man per day.

It must be borne in mind that these figures are for labor alone; the mine furnishes all tools, powder, fuse, caps, candles, trams the ore or waste, and feeds the men. In contrast to this I have repeatedly let contracts to Mexicans in flinty limestone for an adit 4½ by 7 ft. from $1.80 to $2.50 gold per foot, and they have trammed their own rock, furnished everything, and sharpened their own steel, and worked every day except Sundays, making seldom less than 1 ft. per man per shift. I have not at hand my notes on costs collected during my five years in Mexico.

Mr. Carter's estimate of feeding costs is a little high also; our normal cost is 43c. gold per man per day, which includes the table for the staff; it has been as low as 40c. and never higher than 57c., which it reached one month when a shipment of provisions from the States was delayed and we were obliged to pay exorbitant prices to local merchants.

I[1] have already gone into the metallurgy of these ores at some length in the paper previously referred to; it is but fair to mention that the Bonanza is not at present operating a decantation process, but a modern vacuum filter installation with absolute success. I do not feel at liberty to give the figures from the plant, as the manager, P. A. O'Brien, will probably describe it in the near future. I can not agree with Mr. Carter's ideas of the future metallurgy of these ores. That slime plants must be installed is, of course, obvious, but Mr. Carter attributes the failures he experienced in settling these slimes to the presence of hydrates of alumina as such; with this I do not agree. It is the fact of their assuming the colloidal state in the presence of sodium hydrate that prevents their settling and filtering properly; they settle readily out of distilled water, acid solutions, and solutions of calcium hydrate, but when once rendered colloidal by sodium hydrate they can not be completely ionized by the subsequent addition of an electrolyte such as lime. But the use of lime alone removes all difficulties and these slimes are as easily treated as any other slime. Regarding the comparative costs of lime and soda, the lime costs us 5% more than the soda; this is based on the cost laid down here at the mine, the relative efficiency as a neutralizer of acidity, the loss due to breakage of drums in shipment, and other factors. This difference is but slight and the lime is indispensable to good work; the slimes can not be treated without it.

When Mr. Carter says that tube-mills are not required, as there is no necessity of fine grinding, I presume he refers to the oxidized ore only; fine grinding is the only way the sulphide ores can be successfully treated. We are installing a tube-mill here, and there are two others installed in this district; our ores below the water-level are heavily sulphide and their content in gold is higher than in the oxidized zone.

Lastly, the acid treatment of zinc has been discontinued at this mine and we are employing the Mexican practice of washing the zinc in the boxes and running the sludge into the clean-up tank over 40-mesh screen; everything that remains on the screen is returned to the head-box. We have as yet observed no accumulation of shorts after six months; should they accumulate they will be handled as described by me[2] in the *Mexican Mining Journal*, dissolving them in KCN. Evidently Mr. Carter has been out of touch with Nicaraguan matters for some time, as I notice he speaks of "President Estrada," when as a matter of fact Estrada abdicated the chair many months ago; also many other things Mr. Carter writes of were true a couple of years ago, I am told, but have radically changed by now.

Henry B. Kaeding.

Surface Indications of Ore-Shoots in Depth

The Editor:

Sir—W. H. Storms in his contributions on 'Surface Indications of Ore-Shoots in Depth'—the issue of October 22, 1910, and in later issues—has certainly stirred up a great amount of discussion, and while I believe that his conclusions are true in general, there are scarcely any general laws in nature that do not have their exceptions. That orebodies are found under gulches has been demonstrated a number of times, but the ratio between orebodies found under ridges or hills to those found under gulches is so great that there must exist some definite reason for the exceptions. Every gulch formed has a definite reason for its existence. It either represents a general break in the formation, a faulting, a contact of two formations, or a soft place in ore formation. In many instances the evidence of the original cause for a gulch has been obliterated. After it was started and a water course made, it was continued to increase in size and length by the action of the elements and the original soft strata completely washed away and a hard bedrock of possibly another formation entirely is exposed. But usually a careful study of the topography and geology of the country will indicate the reason for its existence and its age with reference to the surrounding rocks and mineral veins of the district.

---

[1] 'Metallurgy of Nicaraguan Gold Ores.' Wilkesbarre Meeting of Amer. Inst. Min. Eng., June 1911.

[2] 'Short Zinc.' *Mexican Mining Journal*, March 1911.

In general, then, when following an ore-shoot in a vein, a change in the vein or a disturbance is unfavorable for a continuance of the ore-shoot, therefore a gulch representing a change in the formation or a disturbance, should certainly mark the end of the ore-shoot or a displacement. However, while the disturbance as evidenced by the gulch is responsible, the end of the ore-shoot does not necessarily occur directly under the gulch line.

The gulch *C*, shown in the sketch, formed on the faulting line *DE* or in the soft vein material between ore-shoots dipping rather flat under the hill *A*. The ore-shoot found in the hill *B* rakes in the same general direction as the fault plane and terminates on it. In this case the ore on the lower levels 3 and 4, would be found directly under the different causes of gulch formation and would probably account for some of the apparent exceptions, as given by F. L. Ransome and others.

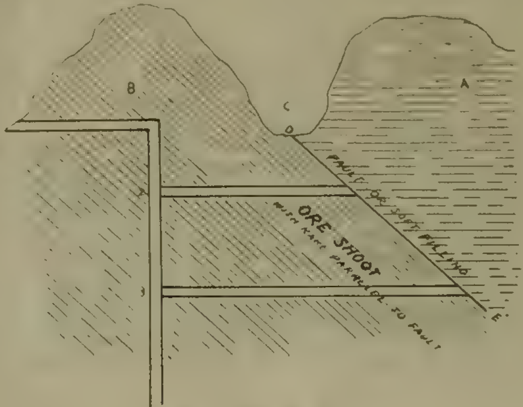
The character of the vein also exerts its influence in the surrounding topography. A hard silicious ore and gangue wears away slower than the country rock and forms a ridge or bold outcrop. On the other hand, a soft ore is eroded more rapidly and the vein is discovered in a depression or gulch. The latter case is the exception to the rule, however, and is seldom met. Occasionally such a case is found in the Tertiary where the vein is a soft talc and the walls hard.

The relation of the topography of the country to veins and ore-shoots can be seen more readily in the desert regions than in a country like California where the surface of the rocks is so heavily covered with loose rock and soil as well as a heavy growth of trees and underbrush. This is one of the reasons that makes prospecting in Nevada easier than elsewhere. In most instances, all of the different formations of an entire mountain range are exposed and the veins, usually outcropping, are easily found and prospected on the surface. Usually the reason for the existence of large gulches can be detected at once. Hills favorable for prospecting show their mineralized character very plainly and the experienced prospector can tell at a glance whether an area is worth prospecting or not. Very few mines have ever been found which did not exhibit some indication of ore on the surface—and the majority of them had 'pay ore' at the start.

In Goldfield I do not know of one pay-shoot that continued across a gulch, and in every case a gulch line is coincident with a fault line. Quite naturally it makes a difference whether the faulting is before or after the formation of the ore. If before, the ore will probably terminate entirely at the fault plane; if after, it often can be picked up again on the other side. There are times again when the merest knife-blade seam crossing the vein appears to have a decisive effect on the content in the ore. An incident of this kind happened to me in the Gold Hill mine in Madison county, Montana. We were driving on a four-foot vein of arsenical pyrite, carrying some chalcopyrite and about $16 in gold and silver. We struck a very narrow seam crossing the vein, showing about $^1/_{16}$ of an inch of oxidized material. The ore from the first round of holes on the other side of this averaged $115 in gold and silver, and from this point we had an ore-shoot several hundred feet in length that averaged throughout better than $40 per ton. There was no faulting of the vein whatever, and this seam continued to the surface. Although I was in the mine nearly every day for a year during this development, I was unable to determine the reason for this condition.

As another instance, I was lately informed by Emmett Boyle, an engineer who was born in Virginia City and has made a life-long study of the economic geology and conditions of the Comstock district, that the ore-shoots not only of the Comstock lode, but also of the Brunswick and Flowry lodes occur at the intersections of these lodes and east and west breaks formed subsequent to the ore deposition, and that these breaks are easily followed by certain topographical features of the country. The large areas of the lodes between these breaks are quite barren and although exploited very thoroughly have never produced ore. There is another series of east and west breaks which is post-mineral, and these breaks are in nearly every instance faults displacing the Comstock lode in several places as much as two hundred feet. These faulting breaks are coincident on the surface with the gulches and ravines on the east side of the mountain range.

At the Windfall mine near Eureka, Nevada, the main vein lies in a contact between the Hamburg limestone and a slate. The ore in this vein is a hard quartz and comparatively low grade. On the limestone side, however, there is a series of cross-fracturing nearly at right angles to the contact. This fracturing is quite prominent at the contact, but gradually fades away in the limestone. Each one of the fractures has been extensively mineralized and large bodies of the limestone replaced by silica forming an ore considerably higher in grade than that in the main vein. Many other instances of the influence of cross-fracturing in almost all formations, could be cited, but the occurrence of ore-shoots at the intersection of pre-mineral breaks is so frequent in the later eruptives, that it can not be attributed merely to coincidence and while, in all probability, no general law can be established, nevertheless, I always consider an intersection of this kind the most likely place to prospect for an ore-shoot if good ore is found in either one of the breaks. All these conditions have an influence in the creating of the topography of the surface, and I believe if it were possible to examine the surface closely enough and to correctly correlate the various exposures, we should find that in the majority of instances, there is a very close relation between the various features of the topography and the position of the ore-shoots beneath.



ORE-SHOOT BENEATH A GULCH.

H. C. Cutler.

Reno, Nevada, October 10.

The platinum market at Ekaterinburg appears as active as before, although there is an idea that such activity is less earnest. The demand on the part of dealers, although apparently as insistent as recently, leaves the price unchanged at 9 roubles 95 kopecks per zolotnik for 83% metal. Osmiridium is in strong demand, and Treuchovy Bros., gold and platinum dealers, have bought a small parcel from the Lower Isset factories at the price of 10r. 80k. per zolotnik. Throughout the Urals only 1½ to 2 funts of this metal is produced per annum. The total production of platinum in Russia in 1910, acording to the figures reported to the Imperial Mint, was 334.575 poods, but the actual production is nearly double this figure.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting.

TO cement brasswork to glass, mix two parts litharge, one part white lead, **three parts** linseed oil, and one part gum copal. Use immediately.

TO MAKE transfer paper, take 2 oz. tallow, ½ oz. powdered black lead, ¼ pt. linseed oil, and enough lamp-black to give the mixture the consistence of cream. Melt together and rub on white paper while hot.

THE following gives the rate of shrinkage in castings made from various metals: Bismuth, 5/32 in. per foot; tin, 1/12 in.; copper, 3/16; lead, 5/16; zinc, 5/16; thin brass, ⅛ in. per 9 in.; thick brass, ⅛ in. per 10 inches.

EXTREME hardness in steel can be produced by heating slightly, then immersing in a mixture of four parts water, two parts salt, and one part flour, till it is thoroughly coated. Then heat the metal to a cherry red, **and plunge into soft water.**

POLISH for silver, gold, or other fine metals is made by mixing a little vaseline with the ashes of burned-out or broken gas mantles. Apply with a rag or finger and polish with a clean rag. The result is a superb lustre, the best finish being obtained by using a soft rag.

A GOOD copying ink is made by putting into two gallons of clear rain water, ¾ lb. gum arabic, ¼ lb. clear copperas (ferrous **sulphate**), ¼ lb. powdered nutgalls, ¼ lb. brown sugar. Mix well, shake occasionally for ten days, and strain. If it is needed before ten days, steep it in an iron kettle until the desired strength is obtained.

NO MINER should ever start his day's work before he has carefully examined his roof by sounding it with a pick or steel drill. Cap pieces for mine posts should always be cut at least 14 to 18 in. long. It is advisable to have the caps cover the entire surface at the top of the prop. Many experienced timbermen advise placing the large end of the prop next to the roof.

CONTINUOUS elevator buckets, if possible, should be loaded directly from a chute, rather than having to dig the material from the boot. In this way, an even load can be obtained and an excessive strain on the belt is avoided. The intermittent or centrifugal discharge buckets, however, must always dig the material from the boot rather than being loaded by a chute.

ACETYLENE gives the hottest known flame, except that of the electric arc. The following figures for the temperatures of flames are the results of recent experiments: Bunsen burner, 1871°; acetylene flame, 2548°; alcohol flame, 1705°; Denayrouze burner, half alcohol half petroleum, [illegible]°; hydrogen flame in air, 1900°; gas **jet flame with** oxygen, 2200°; oxyhydrogen flame, 2420°. These figures all correspond to degrees Centigrade.

A COAL-DUST extinguisher, consisting of a combination of [illegible] the surfaces to be [illegible] the dust, and the simultaneous [illegible] of the dust by [illegible], has been given a demonstration by a Scottish colliery engineer, following a series of experiments extending during the past summer. The apparatus is designed to be operated either by electric motor or by compressed air. It is said it will soon be introduced in some of the coal mines of the Dunfermline district.

IN mixing plaster of paris, do not pour the water on the plaster, but turn the plaster gradually into the water, spreading it about and shaking it in, and not stirring until all the plaster has been added. If mixed in this manner a smooth cream or thin dough without lumps will result. The proper quantity of gypsum is usually enough to peep out over the surface of the water over the greater part of the area, that is, about equal volumes of each ingredient. The addition of glue water to the mixture retards setting.

THE Loetschberg tunnel is 47,678 ft. long and was first planned to be on a tangent. On July 24, 1898, when the main heading had reached a point 1.6 miles from the **portal, it met a cleft filled with sand, gravel, and water. There was a sudden and violent inburst of these materials,** which in a few moments filled up the tunnel for a length of 5000 ft., burying 25 workmen and all the drills and other installations beyond hope of recovery. It is estimated that about 8000 cu. yd. of sand and gravel entered the tunnel. To avoid any further irruption of the materials, **the tunnel was walled up by a 33-ft. wall at a point** 4075 ft. from the portal. The new line leaves the original line at a point ¾ mile from the north portal. No further serious difficulty was experienced in tunneling through the diversion.

WHEN oil is used for firing boilers, **an average of 4%** of the steam evaporated by the boiler is required for atomizing the oil (minimum, 2.39%; **maximum**, 7.4%). In designing a plant a consumption of 5% should be **assumed. In operation if the amount required is much** in excess of 5%, it may be concluded that the condition can be bettered. In certain metallurgical and industrial operations, especially where high temperatures are desirable, the use of air under pressure for atomizing the oil is to be preferred. A reverberatory copper-matting furnace, hearth 80 by 17 ft., with roof arch 30 in. above the surface of the bath on the hearth, required 36,472 lb. oil for smelting 182 tons. The **air was supplied by a Connersville** blower at 9 lb. pressure, and 1 lb. air was required for each 2 lb. of oil burned.

HANDLING of timber for its many uses in mines entails unnecessary waste. A portion of the material is cut away and lost in the process of framing, and if, through decay or fracture, a part of a piece is injured, the entire set is usually rendered useless. In certain situations the sizes of mine timbers could even be materially reduced provided they are kept sound; under present conditions the timber employed is often so much too large as to be still able to do its work after decay has progressed to a considerable depth. The whole theory of preservative treatment is based on the presumption that if decay may be prevented, the **sizes of mine timbers may be materially reduced without** reduction in necessary strength. John M. Nelson, Forest Assistant, United States Department of Agriculture, estimates that 10% of all the material going into underground operations is wasted.

LAND entered as a millsite must be shown to be non-mineral. **Millsites are simply auxiliary to the working** of mineral claims. To avail themselves of this provision of law, parties holding the possessory right to a vein or lode claim, and to a piece of non-mineral land not contiguous thereto for mining or milling purposes, not exceeding the quantity allowed for such purpose, the proprietors of such vein or lode **may file in the proper land** office their application for a patent, under oath, in the [illegible] manner, which application, together with the plat and field notes, may include, embrace, and describe, in addition to the vein or lode claim, such non-contiguous millsite, and after due proceedings as to notice, a patent may be issued conveying the same as one claim. The owner of a patented lode may, by an independent application, secure a millsite, if good faith is manifested in its use or occupation in connection with the lode, and no adverse claim exists.

FAIRBANKS, ALASKA

Chena Mill Makes Test Runs.—Crooks & White Lease McCarty Property.—New Mill on Newsboy.—Tanana Q. & H. Co. Sinks Shaft on Rhoads Vein.

The Chena custom mill has been running lately on several test shipments of ore from various properties. The largest clean-up resulted from 45 tons of rock shipped from the Rainbow quartz claim on Skoogy gulch, owned by Zimmerman & Gordon. About $1640 in free gold was taken from the plates, while the concentrate yielded about $205 per ton. A 10-ton lot of ore from the new find of Graham, Bush & McDonough on Fairbanks creek returned $500. The vein averages between 3 and 4 ft. in width. No further work will be done till pending legislation is settled. The first shipment of ore from the Ryan Lode group on Eva creek, amounting to 9 tons, yielded about $20 per ton in free gold.

The 5-stamp Joshua Hendy mill on the Rhoads-Hall property is busy cleaning up the dump of lower grade ore taken out in development work. As soon as the dump is milled, ore will be drawn from the two years ore reserve in the stopes. Crooks & White have taken a lease on the ground formerly known as the McCarty property. The Fairbanks Core Drill & Mining Co. is prospecting on the Newsboy property. The drill averages 17 ft. per day of one shift, and the 500-ft. level should soon be reached. It is hoped the vein will be cut at that depth. The 5-stamp mill on the Newsboy is almost ready to begin crushing.

A lease on the Rexall group is being worked by Cooper & Stillman. Although only shipping ore is being extracted, a large body of ore assaying about $35 per ton has been opened up that will be available when a mill is placed on the property.

The Tanana Quartz & Hydraulic Co. is opening up the extension of the Rhoads vein on the Bedrock-Chatham divide. The shaft is being sunk by contract. A fault carried the vein out of the shaft at 40 ft., but no cross-cutting will be done till the 100-ft. level is reached.

Jesson Bros., placer operators on Ester creek, have taken an option on the entire holdings of Fred Fay at the head of Chatham creek. These were located by Fay three years ago. Gieske & Nehrland have taken a lease on the Pioneer M. Co.'s property and are already at a good depth. In the effort to sink where water would not bother, two new veins were found. The 3-ft. Huntington mill at the Tolovana mine is crushing steadily, milling about 2½ tons per day of one shift. The rock is of good grade. A mess-house and a bunk-house are being built, and it is planned to do a large amount of development work this winter. Fisher & McGillvray have taken a lease on the supposed extension of the Newsboy vein.

The banner placer property of this season has proved to be the Niggerhead Association at the lower end of Dome creek. Two plants operated by Walter Fisher and Barney Sandstrom have been cleaning up from $15,000 to $25,000 per week each. Fisher has a 150-hp. plant. Hughie McDonald has taken a lease on 17 Goldstream and a 60-hp. plant has been erected. The ground to be worked has just been prospected by the Esby-Crooks Keystone drill. Another boiler of 40 hp. will be used during the sluicing season. Pay has been found on Eva creek and a large plant is working. The extension of the pay-ore has been found by Henry Crooks with a drill, and a plant will be erected there this winter. The dredge managed by Lemmons & Powell is handling a large amount of material. The dredge is on Fairbanks creek and will run until cold weather interferes.

The feature of the annual Tanana Valley fair, held here in September, was the exhibit of rock and minerals from the different quartz claims. All specimens were shipped for exhibition at the Land and Irrigation Exposition in New York. The low water in the rivers is causing great difficulty in landing late freight.

NEW YORK

Financial Uncertainty Depressing.—U. S. Steel Gives Up Lease.—Ray Cons. Copper Co.'s Large Output.—United Verde Reorganizing.—Rumor Goldfield Cons. Is to Reduce Dividends.

There is no occasion for surprise at the lack of interest in mining throughout Eastern financial centres. The uncertainty of the business situation has for the present halted the launching of nearly all kinds of constructive enterprise. This means not only that the promotion of new mining ventures is not being attempted, but that electrification of transportation lines, the construction of new inter-urban lines of transportation, new telephone lines, new hydro-electric power-plants, and countless similar lines of industry which consume copper and other metals are not making the usual demands made by healthy growth and expansion. The unsettlement of the corporate status of so many large organizations has brought about a strange condition of affairs, and the uneasiness which has prevailed for months has not been in any way allayed. The determination of the United States Steel Corporation to give up its lease on the ore lands acquired from the Great Northern railway is the strongest effort yet made by any of the corporations to come within the pale. Were our currency system operated on a different plan, or if we had in this country a system of discounts, it would in part relieve the present tension by allowing the fundamentally good conditions to exert their influence, and the commercial life of the nation would not be obliged to wait for the market pyrotechnics to entirely subside before gaining independent headway once more.

GREENE-CANANEA MILL.

Copper, both the metal and in the share market, has developed a distinctly bearish tone during the week, and it is apparently conceded on all sides that copper must work to lower levels and that nothing can now prevent a closing down of some of the higher-cost producers. There is a good deal of discussion of the commanding place achieved by the low-grade milling coppers, due in part to the new records made by the Utah Copper. The action of Utah shows how the handling of immense tonnages reduces cost and increases profit even on the present metal market. The August output broke all previous records for a single month, while September established a new high record of a little more than 9,250,000 lb. The present output is at the rate of 112,000,000 lb. per year. Not all of the improvements under way at the company's two mills are completed; when they are, a further increase in output is expected. The plants are now handling an aggregate of 15,000 tons of ore per day. The eventual capacity will be 20,000 tons per day. While the development of Utah and the similar properties must be acknowledged as mechanical and metallurgical wonders, it is to be regretted that such mines should be brought to perfection just at a time when the metal market is declining, consumption decreasing, and that the weight of the production so achieved should fall so heavily upon the world's markets.

Ray Consolidated, now recognized as soon to stand second only to Utah Copper in volume of output, is handling 3500 tons of ore per day, and the saving of copper is said to be all that can be asked. There seems to be something of a coincidence in the recrudescence of so many copper properties just at this time. Utah Consolidated, recently the subject of a drastic report by eminent engineers, is again a dividend payer. Granby has developed a fair ore reserve, has bought two properties, and is now held in check only by the strike in the British Columbia coalfields. Calumet & Arizona, once a sensation, then reported to have reached practically the limit of profitable operations, has consolidated with Superior & Pittsburg and has recently opened a large orebody. The old scrap heap of the Arizona Copper is to be replaced by a modern plant. Greene-Cananea has a new plant ready for immediate operation at capacity, and is now expected to pay a semi-annual dividend of 20c. per share about the first of the year. North Butte is developing on a large scale. Shattuck-Arizona is building a smelter. The United Verde is rebuilding on account of cave-ins. To say nothing of the new production, it is easy to see that the older properties could turn out a flood of red metal if the market demanded it. New mines in foreign countries are figuring more and more largely each year in the world's supply of copper; Russia's output has trebled in the past ten years, having increased from 18,681,000 lb. in 1901 to 54,302,080 lb. in 1911, which makes Russia nearly independent of imports, and, what is equally important, reduction works have been built with a view to increased production, prepared to handle all the metal produced without depending on foreign refineries. The product of Japan is increasing. American interests in South America are seeing the turning point in their investments. The vast amount of copper that could be produced almost immediately is stupendous. It would be a bold hazard to even attempt an estimate of the amount of copper that could be won from the earth in a twelvemonth under stimulus of high prices. Between the revamping of old properties and the creation of new ones, there is a staggering amount of copper awaiting a market.

Consolidation of copper properties is no longer the fashion. The Superior & Boston and the Arizona Commercial are to travel separate paths. The Arizona Commercial reorganization is to be effected independently, and Charles Sumner Smith, president of the Old Dominion company, will act as president and direct future operations. Ohio Copper is still suffering from too much Heinze, although the mill is handling 4500 tons of ore daily and apparently is winning a reasonable profit from its operations, the issue is dead and without any following. E. A. Wall, who has become something of a factor in Ohio Copper, has acquired control of the Daly Mining Co. at Park City, Utah, and has vetoed the merger of that property with the Haggin-Hearst mine, the Ontario Silver. Ontario is one of the few mining properties that has maintained a place on the New York Stock Exchange for many years. Homestake, also a Haggin-Hearst property, is on the 'big Board', but, like Ontario, trades are not recorded, except at rare intervals.

The market action of Goldfield Consolidated during the week has been much commented upon as foreshadowing a reduction in dividend rates. All surmise is based upon the only question involved, the actual ore reserves in the mine. The recent reduction in quarterly distribution made by the Kerr Lake, which, like Goldfield Consolidated, paid 50c. per share quarterly, has made the public uneasy as the impossibility of holding out to the last large dividend and getting out of the stock at the same time is gradually realized. A large part of the public, which follows mining enterprises, would continually enjoy eating its cake and keeping it at the same time.

The recent corner in tin has been a sore spot with the London Metal Exchange, and a new rule has been passed defining standard tin, which must be accepted as delivery as against sales of tin from the Malay Straits. The regulation is similar to that which exists in regard to copper and is expected to make it much more difficult to successfully engineer a corner in the metal. It is not only in the matter of production that the Guggenheim interests are assuming a commanding place. The American Smelters Securities Co. is encroaching steadily upon the United Metals Selling Co. in the matter of selling contracts, and in all probability will handle some half million pounds of metal in 1912, which will make this agency the largest copper broker in the world.

A special meeting of the directors of the La Rose Consolidated Mines Co. has been called for next week, and the shareholders are anticipating some definite action in regard to the distribution of the treasury's present cash surplus of about one and a half million dollars. Wettlauter, the silver property at South Lorrain, operated by the Lewisohn interests through Canadian Silver Mines Exploration Co., is building a mill to handle its low-grade ores, while continuing to ship its high-grade output as heretofore. Wettlaufer ores run from 2500 oz. for the high-grade ore to 200 oz. for the concentrating ores. The Porcupine Central fiasco seems to have been about the last gasp of the Porcupine market activity. So far as the market is concerned, the excitement is evidently all over. The era of exaggeration having passed, it remains to be seen what will be done in the way of actual mine development and making.

LONDON

Treasury Reserve Planned for the Levant.—Proposed Importation of Foreign Miners to Cornwall.—Botallack Mine Finds Forgotten Ore-Supply.

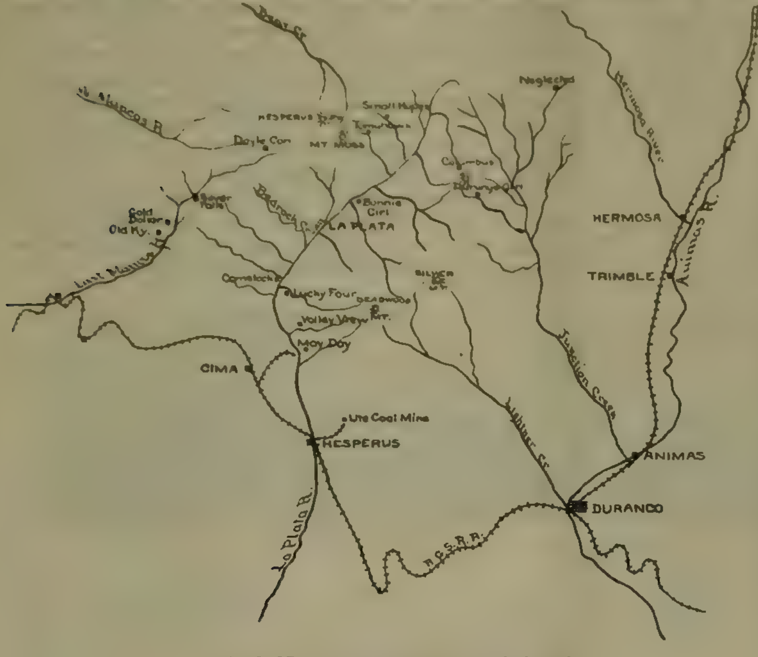
It has been proverbial during recent years that the Levant mine, near Land's End, has a more old-fashioned set of directors and shareholders than any other mine in Cornwall, not even excepting East Pool. To speak a word against the cost-book system within a mile of the count-house would entail serious physical consequences to the rash adviser and critic. There are indications, however, of the first faint dawn of a new era, and within the next four years great changes may be expected. The present guiding influence comes from Francis Oats, the chairman of the De Beers Diamond company, and from his son, F. Freathey Oats, the chairman of the committee of management of the Levant. For years it has been the practice to divide all the profits, and leave no margin for a rainy day or for the provision of extra capital expenditure. At the regular quarterly meeting held last week, Mr. Oats, senior, delivered an impressive address to his fellow shareholders, and recommended that quite half of the profit should be kept in hand. He pointed out that the lease of the mine expires in four years, and in negotiating for a renewal, plans necessitating the spending of much capital will be demanded by the lords. Many things are required urgently even now. A new shaft ought to be sunk vertically to meet the main vein at 2400 ft., and, from there, inclines sunk to follow the vein underneath the sea. Then a system of ventilation must be adopted, for the air in the lower levels is stagnant and humid, and work is done under depressing circumstances. Quite £50,000 will be required for this new work. But a further question at once arises, whether it will be worth while doing all this unless steps are taken to provide sufficient labor. It is the cry made by everybody desirous of reopening or extending the operation at Cornish tin mines, that sufficient skilled labor is not available. Twenty to thirty years ago, when the permanent depression set in, the miners emigrated in a wholesale way, and are now scattered over the face of the earth, doing better than they ever did or ever could in the old county. They will never return, and more will follow them abroad. Mr. Oats proposes that foreign labor be imported, and he braves local opposition by showing that the Cornishman is a foreigner when he is in another country. He argues that all sorts of heterogeneous communities prosper abroad in the mining districts, and that the founding of an Italian or Hungarian colony at Pendeen would be nothing very dreadful. There will, at first, be an almost unanimous opposition to the introduction of foreign miners, but the company will probably introduce the new idea gently, without raising unnecessary friction. The Levant mine has been working continuously since 1820.

The Botallack mine, adjoining the Levant, has apparently had a stroke of good luck recently, and it certainly wanted it. For three years, since its reopening by the Allen Meyerstein group, the results have been disappointing and the new stamps are only partly employed, working only on low grade dump material and cleanings from old workings. The average recovery is only about 12 lb. black tin per ton, which of course does not pay. It is now reported that in reopening one of the levels, a large amount of broken ore has been found, left behind as filling in days when copper was being followed chiefly. Frank Merricks, the consulting engineer, is making an examination. I am given to understand that there is a great deal of this ore, and the local opinion is that its presence will afford some indication of a workable lode. In all probability, important news on the subject will be published before long.

The news from the St. Agnes district of Cornwall is both good and bad. The pleasant event is the discovery of ore averaging 100 lb. of black tin per ton over a stoping width of 6 ft. at the Wheal Friendly section of West Kitty. This mine has had many misfortunes during recent years, and the production has fallen seriously. A year ago the property was provisionally acquired by the Schiff group, and their exploratory work was disappointing for a long time. The manager, T. H. Prisk, Jr., has made a close study of the geology and ore deposits of the district, and he decided to cross-cut at 320 ft. below the adit to intersect the West Kitty lode. The result was as described. The country at this point is dislocated by a cross-course, and in all probability the continuation of the lode will have to be sought at a lower level. For this purpose the shaft is being sunk deeper. The discovery will have a most encouraging effect on St. Agnes people. The bad news referred to at the beginning of this paragraph relates to the neighboring mine, Wheal Kitty. This has been worked successfully for several years on a small scale under the direction of J. H. Collins, and the prospects of continuing to obtain a regular supply of good quality ore have been consistently bright. It is disappointing, therefore, to hear that at all the working faces the content has decreased and that the average extraction is not higher than 20 lb. per ton. At this figure the balance between profit and loss will depend entirely on the price of the metal, and unfortunately this shows signs of falling from the high level to which we have been accustomed during the past year or so. The discovery at West Kitty will help to put heart into Mr. Collins and his friends, because it is for the express purpose of tapping this particular lode that they are now sinking the new Sara's shaft.

LA PLATA, COLORADO

Many Properties Active. Mines Tied Up by Litigation. Cumberland to Build Pipe Line.



MAP OF LA PLATA DISTRICT, COLORADO.

About 200 pack-animals are constantly employed transporting ore to the May Day spur, averaging two trips per day, from the various mines along La Plata gulch and its tributaries; and about 250 miners are engaged in actual production in this district, while many others are prospecting and doing a large amount of dead work in the old mines which are being reopened and explored. The Neglected, May Day, and Idaho, the three largest producers in the La Plata district, are still closed down.

Evidence is being taken before Judge Hinsdale at Denver in the suit between the May Day and the Idaho over the ownership of 300 ft. of rich vein from which the Valley View M. Co., owning the Idaho, has extracted a large amount of ore. One shipment of 11 tons from this vein is said to have brought $40,000 at the Durango smelter. Payments amounting to about $80,000 which were due the Valley View company at the commencement of litigation are still tied up at the Durango smelter pending the result of the suit. The suit is, of course, a decided detriment to the camp, for these two mines if worked to capacity would easily have produced $1,000,000 during this year. During the last seven months of operation, last year, the Valley View company paid $20,000 each month in dividends.

On the property of the Van Emmett M. Co., a short distance above these mines, the Price lease and the Incas lease are both making heavy shipments of ore averaging $25 to $75 per ton in gold. The Incas Leasing Co. is planning to erect a cyanide mill for the reduction of the lower-grade ores in the dumps and stopes. The Cumberland company has let a contract for the construction of a 7000-ft. pipe-line to supply water to the mill from the new reservoir. An 1100-ft. cross-cut is being driven to drain the old Columbus mine, not far from the Cumberland. The property has a 300-ft. shaft which has been filled with water for fifteen years.

The Lily lease on the Ten Broeck is making a small but steady production of high-grade ore; and the Blue Dick, situated on the ridge just east of the Bonnie Girl mill, is the scene of a recent discovery. Assays from 10 to 15 in. of the vein show results of $200 to $500, with a 2-in. streak which runs $3200 per ton. Hollingsworth & Reeber have opened a large body of $40 ore and have bonded the property to Price & Co., who have a rich lease on the Van Emmett ground. This is an old district, dating back to 1873, when the discovery of gold on the La Plata river created much excitement. Parrott City, which was built at the mouth of the canyon, was the first town in the county, and was for many years the county seat. Most of the orebodies so far discovered are small, but the ores are rich and a number of mines have made excellent records. If the district were not so remote it would have prospered much more than it has. But the steady output of the last few years has served to demonstrate the real worth of the district, and it is likely that progress will be more rapid in the future. The district is rather quiet at present, but the outlook is cheerful.

BLACK HILLS, SOUTH DAKOTA

Free Assays to Promote Prospecting.—Anaconda to Build Mill.—Denver Men Buy Forest City Group.—Record Bullion Output.

With the idea of encouraging prospectors the Deadwood Business Club has lately perfected arrangements whereby assays for prospectors are made free of cost. The matter was under discussion by the club for some time. Ore samples are received by the secretary of the club and forwarded to different mining company assay offices throughout the district. In this way the work is divided so that no office is burdened with an amount of work which would be troublesome. The operating companies were very glad to enter into this arrangement with the club, and the result has been a stimulation of prospecting throughout the Black Hills. The only restrictions which the club has placed upon the offer are first, no sample shall consist of more than five pounds; second, not more than ten samples shall be submitted during any month by any person; and, third, the offer is limited to prospectors only. The secretary of the club, when the mining companies make out their returns, issues a certificate in the name of the club.

Announcement is made by the Anaconda G. M. Co. that funds have been pledged sufficient to complete the blocking out of the ore and the erection of a large mill. This company's property is situated near Roubaix, Lawrence county. A. E. Hall is superintendent.

Denver men have bought the Forest City group of claims near Hill City, Pennington county, for $30,000. There will be three equal payments. The purchasers have bound themselves to sink a shaft to a depth of 400 ft. and have the privilege of erecting a mill and treating such ore as they may extract in the course of development.

During the quarter ended September 30, bullion purchases at the United States Assay Office at Deadwood amounted to $1,855,000. All of this was produced in the Black Hills district, and it is thought to be the largest amount ever produced in a similar length of time in the country. It does not, however, represent the entire output of the Hills, as there is ore shipped to smelters and some bullion produced which is not marketed at this assay office. As a whole the mining industry of the Black Hills is in a prosperous condition at the present time. The production is growing steadily and without doubt the output of the present year will surpass any previous twelve-month.

A judgment of $14,000 was given in the U. S. court in favor of the Portland and Clinton mining companies for trespass and extraction of ore by the Imperial Mining Co., and operations have been suspended by the Imperial company. P. H. Bertschy, who was leasing on the Imperial, also has discontinued operations.

A Wedge mechanical roaster is being erected by the Golden Reward company at its mill at Deadwood to handle a sulphide ore, recently discovered, which differs from anything previously found on the company's ground. The ore will be roasted for cyaniding, and if it proves successful in operation, it will form a portion of a large new plant. The mill will be close to the present plant. The ore, which is from the Astoria vein, is mined quite wet, and a drier at the mine is planned. The orebody is opened up to supply 500 tons per day.

The new mill of the Trojan M. Co. is handling about 150 tons of ore per day, half of the capacity which the plant will have when certain changes are perfected. A 7-ton gasoline locomotive is used for hauling the ore from the mines to the ore-bins, which are situated on the side hill at the rear of the mill. These bins are constructed of reinforced concrete and timber and have a capacity of 1000 tons. The ore is drawn from them to a No. 5 Gates crusher, which reduces the product to $1\frac{3}{4}$ inch, and it then drops to a belt-conveyor which delivers it to the mill-bins. The belt-conveyor is 110 ft. long, from centre to centre, and has an upward slope of 16°. The ore from the mill-bin is fed to 16 by 36-in. Eclipse rolls, the strong cyanide solution being added to the ore at this point. The product of the rolls runs in launders to two 7-ft. Trent-Monadnock mills, where it is crushed to about 30 mesh. Classifying is done in four Dorr-Duplex machines, the sand running in launders to five 200-ton sand-tanks which are 28 ft. wide and 8 ft. deep. The slime goes to a Dorr thickener, where the moisture is reduced to about 55%. The slime treatment is perfected in three Pachuca tanks and a stationary leaf-filter. Precipitation is accomplished in three zinc-boxes. The standard mill solution has a strength of three pounds KCN per ton, and the weak solution one pound per ton. Sand treatment consumes five days, and slime agitation five to six hours, which with the filtering makes about ten hours. The Dorr thickener is to be placed in a 40-ft. tank. It is now running in one of the 28-ft. sand-tanks, and in order to bring the capacity of the mill up to 300 tons per day it will be necessary to build this larger tank and move the thickener. When this change is made it will give the plant six sand leaching-tanks, or a total leaching capacity of 1200 tons. The slime department is sufficiently large to handle its share of a 300-ton run. Electric power is used throughout the plant. H. S. Vincent, of Deadwood, is general manager; W. H. Weigand, of Trojan, mill superintendent, and H. Slaughter, also of Trojan, mine superintendent.

The New Reliance Gold M. Co., near the head of Annie creek in the Bald Mountain district, is successfully operating its reconstructed 20-stamp cyanide mill, and plans are being prepared for an additional ten stamps.

BUTTE, MONTANA

Butte-Ballaklava Shuts Down Again.—Deer Lodge Valley Smelter Case Still Undecided.—Heinze Retirement from Davis-Daly Causes Surprise.

The Butte-Ballaklava company has stopped active mining again and the shipping of ore will not be resumed until some repairs to the shaft are made. The company did not make over one or two shipments of ore from the 1400-ft. level to the East Butte smelter and the ore did not run over 4% copper.

Many are watching for news from Washington in regard to the action on the part of the Deer Lodge valley ranchers when a motion will be made to bring up for argument on appeal the celebrated fume case, a notice of which was filed with the court a few weeks ago.

The announcement received here that F. Augustus Heinze had retired from the presidency of the Davis-Daly company came as a surprise to many people in view of the interest shown by him in the property while in this city a few weeks ago. A year ago, just before W. H. Wiley made an examination of the Colorado mine, Mr. Heinze stated that the Colorado was not of much value and that it would not pay to put any more money into development work. However, after Mr. Wiley had made his investigation and recommended development work, and some good orebodies were found, Mr. Heinze changed his mind, and during his examination of the property a few weeks ago he reached the conclusion that the ore blocked out was of a grade sufficient to warrant it being shipped. The ore is now going to the Washoe smelter and the returns are declared to be quite satisfactory. According to some persons here there is an element connected with the Davis-Daly which desired that Mr. Heinze be eliminated from the active management of the company. Boston interests are largely in control, as evidenced by the fact that the offices of the company are to be at once removed from New York to Boston.

The Butte Central Copper Co. is carrying on development on the 500-ft. level of the Ophir in the hope of finding the rich body of ore discovered on the 300-ft. level, from which all the shipments have been made for several weeks past. The big electric pump had been placed down at a depth of 1000 ft., but as the ground was too soft to cut a station down to 50 ft. below that point the pump has been taken to the 500-ft. level. It is intended to lower the water to the 800-ft. level and to develop the property down to that point. In the course of a couple of weeks the company intends to increase its shipments from 50 to 100 tons per week, getting some of the ore from the 500-ft. level.

General Mining News

ALASKA

Juneau

The net operating profit of the Alaska Mexican G. M. Co. for the month ended September 15 was $22,247, according to the regular report recently issued. The company crushed 18,763 tons of ore, from which 156 tons of sulphides was saved. The value of the free gold was estimated as $28,239, and the value of the sulphides as $32,850. In the report the value of 753 tons of United ore, $4278, is subtracted from the gross, leaving a total production for the company of ore valued at $56,811, with a realizable value of $56,243. Operating expenses amounted to $33,996. During the month $6202 was spent on construction. The yield per ton of the ore milled was $3.02. The stock of broken ore was increased 15,360 tons. One hundred and ninety-two feet of development work was done during the month.

The report of the Alaska United G. M. Co. for the month ended September 15 shows an operating profit of $33,597 for the company from the Ready Bullion and 700 Ft. Claim. For the Ready Bullion claim the report includes the following items: Tons of ore crushed at R. B. mill, 15,316; tons of sulphides saved, 352; estimated value of free gold, $22,935; estimated value of sulphides, $17,712; realizable value of production, $40,151; operating expenses, $29,224; net operating profit, $10,927; construction expenses, $7026; yield per ton of ore, $2.65; development work done, 156 ft. For the 700 Ft. Claim the report includes the following: Tons of ore crushed at 700 Ft. Claim mill, 20,916; sulphides saved, 390; estimated value of free gold, $28,537; sulphides, $27,426; total production, realizable value, $55,386; operating expenses, $32,715; operating profit, $22,670; construction expenses, $3730; yield per ton, $2.67; development work, 378 ft.; stock broken ore increased 7207 tons.

IDITAROD.

Prince William Sound

Peter S. Erichsen has sold his copper claims on Glacier creek, 12 miles east of the Bonanza mine, to Cappel, Radclyffe & Company.

The Ibex M. Co. stockholders held their annual meeting October 9, say reports from Valdez, and authorized the board of directors to acquire more property for consolidation with the Ibex mine, which is situated on the glacier. The company in the past season has expended $10,000, which was paid out for labor and supplies.

Al. Grigsby and T. J. Devenney have taken a bond on the C. G. Debney property on Solomon gulch. They will continue operations throughout the winter.

The Tanana

The probable production of Iditarod for the season will be about $3,500,000, according to the estimate of Thomas J. Nestor, an Iditarod banker quoted in an Associated Press despatch. The population of the camp is estimated by Mr. Nestor to be about 2500. A prosperous season is expected for next year.

ARIZONA

Gila County

(Special Correspondence.)—An attempt is being made by the Cactus Copper Co. to redeem some of its earlier promises by the purchase of new properties. Some negotiations were had recently looking to the purchase of certain gold claims near Radersburg, Montana, but nothing definite has been announced as yet.

Globe, October 23.

Fire on October 21 destroyed the timbering and equipment of the Kingdom shaft of the Old Dominion mine, state reports from Globe. The men were at luncheon on the tenth level and escaped through 'A' shaft. The shaft was 10 ft. below the tenth level, sinking was in progress, and connections had been made with the workings by cross-cuts on the sixth and tenth levels and by a raise from the twelfth level, according to the report, when the fire broke out. The men had just blasted a round of holes before going to their luncheon. Bulkheads were placed in the drifts and the fire was confined to the shaft. The building containing the transformers and the electric hoist was saved. The financial loss will be large, but the output of smelting ore will not be affected. The production of concentrating ore will be decreased temporarily by 40 per cent.

The Summit Copper Co., operating under lease and bond the Gibson mine, 16 miles west of Globe, has stopped work, but will retain three men to keep the mine free from water. The shut-down is thought to be temporary.

The Barney Copper Co. will resume sinking in its two shafts in December. J. D. Coplen, of Globe, made the announcement of the resumption of work. The property adjoins the Live Oak ground.

Maricopa County

Reports from Wickenburg state that A. J. Kellis has located placer claims covering 20 acres, on which the deposits assay $100 per cubic yard.

The concentrating plant of the Monarch M. Co. will have a capacity of 100 tons of ore per day by Christmas. The additional machinery is on the way. E. D. Akin is managing engineer and C. W. Platt superintendent for the company.

Pinal County

The Ray Con. Copper Co. will start shipping concentrate to the Ray smelter, which recently was acquired by the A. S. & R. Co., about January 1. The Ray at present is shipping its concentrate to the A. S. & R. Co. smelter at El Paso. The company's production for this year is estimated at 25,000,000 lb., while next year the output should be 40,000,000 lb. of copper. The output of refined copper for this year, it is estimated, will be 17,000,000 pounds.

Yuma County

J. E. Kreeps, of Los Angeles, has taken a lease and bond on the Red Paint group of seven claims from J. F. Raney, according to recent reports from Parker. The claims are about nine miles northeast of Parker. The lease and bond run for five years, with monthly payments. The property is on a hill of iron oxides, according to press reports, the mineral content being of special value in the manufacture of paint and as a flux. Kreeps will start work about November 1.

CALIFORNIA

Nevada County

The Union Hill company has intersected the Lucky vein at the 300-ft. level. At the point of intersection it is about 7 ft. wide. As below 400 ft. the Lucky vein is in virgin ground, never having been worked below that depth, much interest is shown in the discovery by the Union Hill company, which will thoroughly develop it. In the early days the Lucky mine was one of the principal producers of the district.

SACRAMENTO COUNTY

(Special Correspondence.) Dredge No. 8 of the Natomas Con. of California was damaged and possibly destroyed by fire on October 20. The extent of the loss is not known at present, and an investigation is under way to see what can be saved. The fire was caused by an explosion in the oil transformer used in connection with the motor. The explosion threw burning oil over the walls of the room, and the flames made such quick headway that the efforts of the crew to put out the fire were ineffectual. The fire occurred early in the evening.

NATOMA DREDGE NO. 8.

The Natomas company is building, at Natoma, dredge No. 10, which will have a hull of steel throughout, instead of wood, as in former dredges. It will have 15-cu. ft. buckets, and may be in commission in the spring. It will be equipped with Bucyrus machinery.

Sacramento, October 23.

SIERRA COUNTY

Press reports quote C. C. Derby, manager of the Tightner mine at Alleghany, as saying that the new 10-stamp mill recently built there is running smoothly and has been operated steadily excepting a few brief stops for repairs incident to starting a new plant. The mill will be run during the winter months on ore that has accumulated on the lower dump and that which has been stoped from the newly opened vein. It is reported there is ample water for operating. There will be no cessation of activity in the winter months.

COLORADO

CLEAR CREEK COUNTY

Work was resumed last week at the Linn mine and mill. Stephens Bros. & Olds have a lease on the property.

SAN JUAN COUNTY

It is rumored that electric power may be used in the next few months at the Frank Hough mine, according to reports from Ouray. Electric power would necessitate the construction of only two miles of power-line. Work was to be started last Monday on driving a 500-ft. contact on the 3500-ft. development adit planned for the mine. A good start on development adit already has been made and steady progress is expected.

TELLER COUNTY

The Kavanaugh mill at Cripple Creek will be doubled in capacity in the next three months, and five or six more tanks will be installed. The mill can handle at present about 1000 tons per month.

Carl Johnson, lessee of the Maggie mine on Raven hill, Cripple Creek, has purchased the steam-hoist, compressor, and other machinery of the Rittenhouse mine on Gold hill, and is erecting it at the Maggie. He will purchase another boiler. The shaft, now 300 ft. deep, is to be sunk 100 or 200 ft. in the near future.

The five No. 2 R. Draeger helmets and the pulmometer ordered by the Portland Gold M. Co. will be delivered about December 1. At that date the mine-rescue car of the U. S. Bureau of Mines and a corps of men under J. C. Roberts will be sent there. The Portland employees then will be given expert instruction in mine-rescue work. Frank Smale is manager at Victor for the Portland company.

Ore assaying about $30 per ton has been found at the surface on the Comet claim of the Isabella estate, Bull hill, where Lees & Co. are working. The Requa Savage shaft, on the east slope of Beacon hill, has been temporarily shut down by the lessees.

The Lewis Mining Co. has been incorporated to conduct mining operations, principally in the Cripple Creek district. The incorporators are F. E. Brooks, M. B. Hurley, and G. W. Bierbaum. The corporation is capitalized at $150,000 and has its principal place of business at Colorado Springs.

The Portland G. M. Co. paid a dividend of 2c. per share on October 17. The new mill, during the quarter ended September 30, treated 29,599 tons of low-grade ore at a net profit of $33,111. The total net profit of the company from the mill during the first nine months of the year was $100,939. It is rumored that tube-mills will be added to its equipment. Additional tanks and machinery are now being erected there and excellent results are being obtained in the mill.

Messrs. Starkweather and Wilson, lessees of the Ingham claim of the Doctor-Jack Pot estate, on Raven hill, last month shipped 12 cars of ore, from a chimney opened on the adit level. The Hahnewald brothers, of Leadville, have installed machinery at the Old Gold mine, on which they have a long lease and propose to start active working at an early date.

IDAHO

BONNER COUNTY

William M. Ridpath, of Spokane, reports that the Pittsburg Mining Co.'s property near Lakeview has returns from several hundred tons of ore from the No. 1 tunnel ranging from 80 to 127 oz. of silver per ton in carload lots.

SHOSHONE COUNTY

With the price of spelter, lead, and silver as at present, it is reported that the Federal M. & S. Co.'s common stock will not be on the dividend list for some time.

Charles McKinnis, manager for the Caledonia Mining Co., operating in the Coeur d'Alene district, says in a letter to the shareholders that the lower adit, run from Deadwood gulch to tap the vein at a depth of 800 ft. below the present lowest working, has passed through the Osburn fault and is now making good progress. The compressor-building and a dry-house, 16 by 30 ft., have been completed, and the foundations are in place for the machinery at the adit mouth.

Robert Sheffels, president of the Jack Waite M. Co., operating a property of the same name near Murray, reports that the face of the main adit shows 3 ft. of clean shipping ore and 30 in. of fine concentrating ore. The adit is now in 1450 ft. and at a depth of 600 ft. has penetrated the shoot for 45 ft. and the orebody is widening. Frederick Burbidge, formerly manager of the Bunker Hill

& Sullivan mine, is looking over the Jack Waite and other properties to determine if the Washington Water Power Co. shall extend its transmission lines to the district. Pending the construction of a mill, the company will resume the shipment of its first grade ore, though it involves a wagon haul of 12 miles to the Oregon Washington Railroad & Navigation Co.'s line at Eagle.

Twenty thousand dollars' dividend, at the rate of 2c. per share, paid October 21, brings the disbursements of the Hecla M. Co. to $210,000 for the first ten months of 1911, and to $2,220,000 in the total amount paid. The cash surplus on hand amounts to $216,471. Profits for the year ended July 31 were $238,850, according to the report submitted to the stockholders at the annual meeting at Spokane, when it was decided to pay an extra dividend quarterly so long as the present earnings continue. The shareholders also arranged to end the fiscal year on December 31, instead of July 31 as heretofore, and changed the date of the annual meeting from October 6 to the second Tuesday in April. The report of the directors states that the ore reserves in the Hecla mine at Burke, Idaho, are sufficient to last five years at the present rate of production. The mine now is well developed to the 1200-ft. level. Sinking of the main shaft to the 1500-ft. level is in progress, 120 ft. of this work already having been acomplished. The officers and directors were re-elected.

BUNKER HILL MILL.

The Bunker Hill & Sullivan M. & C. Co. has paid its 169th dividend. It was the usual monthly disbursement of $65,400, bringing the total to date to $13,028,850. The Bunker Hill mine and mills are situated at Wardner and Kellogg.

MONTANA

LINCOLN COUNTY

(Special Correspondence.)—F. C. Schrader, of the U. S. Geological Survey, who during the past summer made an examination of the placer ground on Libby and Kennedy creeks, in northwestern Montana, has made his report, and estimates that there is $100,000,000 worth of gold in the deposits, much of which, he states, to judge from the attention which the district is receiving, will probably be mined in the near future.

The report states that "tests made of the deposit in six different shafts, fairly well distributed over about half a square mile in the southern part of the basin, show the gold content of the deposits to range from 20c. per cubic yard near the surface, to about $5 per cubic yard in the bottom foot of gravel next to bedrock. The deposit in the southern part of the basin seems to contain on the average about 80c. per cubic yard, including everything from the surface down to bedrock, or about $4 per cubic yard at bedrock. This would amount to about $17,360 per acre."

Two companies are now operating in the Libby creek district, and at least two others are expected to install plants during the coming year. Some of the ground is admirably adapted for dredging operations, but no dredges have as yet been installed.

Libby, October 17.

MISSOULA COUNTY

Frank Thomas, of Missoula, has reported that the $100,000 gold dredge of the Kennedy Creek gold mine has started operations. The dredge has a daily capacity of 2500 cu. yd., and it is estimated that the gravel will yield large returns, as a recent report upon the district by F. C. Schrader indicates that the gravel is very rich.

MONTANA

SILVERBOW COUNTY

The North Butte M. Co. has paid a quarterly dividend of 30c. per share. The report of operations, accompanying the dividend checks, states that a total of 4053 ft. of development work has been done. The ore reserves have decreased, as the amount of ore blocked out in the Snowball vein has not kept up with the ore in the stopes, and the development work practically has been confined to this vein. The opening up of the three lower levels of the Edith May and Jessie veins will be rushed. Several months will be required to block out these orebodies.

NEVADA

CLARK COUNTY

Work was resumed last week in the Duplex mine at Searchlight. Most of the week was devoted to repairing damage due to the failure of former operators to draw out the water in the pipes and to safeguard the condition of the machinery when the property was shut down. The machine drills were used on October 20. G. F. Colton is the present owner of the property.

Work has been resumed at the Searchlight-Parallel mine, near Searchlight, and extensive development work will be done, according to recent press reports. T. D. Forney is in charge of the property.

A vein of ore assaying about $50 per ton has been discovered at the Luisa claim, owned and operated by Nels Nelson, state reports from Searchlight.

ELKO COUNTY

Sixty-five per cent of the capital stock of $1,500,000 in shares of a par value of $1 each of the Bluster Mining Co. of Jarbidge has been taken on option and bond by Patrick Clark of Spokane at 50c. per share. Development work will continue under the present management until Mr. Clark takes charge of the property. The company has $20,000 and 700,000 shares of stock in its treasury.

ESMERALDA COUNTY

The Goldfield Florence company has reduced its working force by 28 men, the reduction being due to a shortage of ore. The mill will be operated eight hours per day, with a production of about 100, instead of 170 tons, per day. Seven power-drills will be kept going. The shaft will be sunk deeper and other levels will be developed.

The rich vein on the C. O. D. Con. property from which some $15,000 was taken about three years ago, but which was lost, has been rediscovered by Elmer Lowden and Howard Hardwick, lessees on the Victor claim, according to reports from Goldfield. The ore is said to assay between $250 and $500 per ton.

HUMBOLDT COUNTY

The Yellow Dog Mine Co. has been incorporated to develop the Yellow Dog Mining Co.'s property in the Dyke section of the Pine Forest range. The company is capitalized at $1,000,000. The entire issue is treasury stock and is assessable. S. L. Baker and L. K. Baker of Winnemucca lead the board of directors.

Rich ore has been discovered on the Golden Horseshoe property in Wild Horse canyon by Stall Brothers, according to a recent report from Lovelocks.

NYE COUNTY

The Fairview mill is to be moved from Shoshone creek to the mine, to eliminate the cost of transporting the ore. The Blue Jacket mill is to be ready for crushing ore in a few weeks. C. E. Rice is manager of the property.

Construction has been commenced on the Round Mountain Tungsten M. Co.'s mill on Shoshone creek. The lumber and first load of machinery are on the ground, and the rest of the machinery is reported to be at Tonopah. Carl Goblin is superintendent of the mill.

Development has been resumed at the Hoosier property. The shaft is down 335 ft. Tom Baker is superintendent.

The construction of the new customs mill and smelter to be erected at Tonopah by capitalists of that place will be started at once. The mill will be equipped with ten stamps, two tube-mills, and a cyanide plant with Dorr classifiers and Trent agitators, and will be built according to plans prepared by John G. and Charles Kirchen. A sampling plant will be constructed in connection with the mill, which is to be operated by electric power. To handle the project the Associated Mining Co. has been organized under the laws of Utah, capitalized at $50,000. It is a close corporation. J. G. Kirchen, who is manager for the Tonopah Extension M. Co., is one of the principal stockholders, and will be in charge of the new mill, which will be situated on the property of Manhattan Con. M. Company.

ROUND MOUNTAIN.

The quarterly report of the Round Mountain M. Co. shows a saving of 30% in ore-treatment, or $1.90 per ton. The mill is running well. R. H. Ernest is superintendent for the company. J. A. Stephenson and Chester Small, who own a quicksilver claim four miles east of Round Mountain, are negotiating with several companies to supply their mills with quicksilver, according to recent reports from Manhattan.

Storey County

The production of the Comstock mines last week amounted to $42,158, or nearly $3000 more than the previous week, according to the reports of the superintendents of the various properties. The Ophir was in the lead with a production of $21,392, the output being 400 tons of ore with an average assay value of $53.48 per ton. The Mexican hoisted 230 cars of ore with a gross assay value of $15,562. The Crown Point produced ore valued at $5204. The total production of the North end mines was $36,954. The Mexican output included the largest amount of high-grade ore ever extracted in one week from the south end of the stope above the 2500-ft. level, 129 cars, averaging $116 per ton.

White Pine County

The large bunkhouse of the Nevada United M. Co. at Ward was destroyed last week by fire, the origin of which is not known. The total loss is estimated at $4500. The company's loss was $3000, one-third of which is covered by insurance.

NEW MEXICO

Socorro County

(Special Correspondence.)—The Ernestine M. Co. milled 740 tons of ore during the week, yielding 56 sacks of concentrate. In addition, 9250 oz. of gold and silver bullion was smelted. New mortars for the battery are on the way from Silver City. The power-plant building with foundations is completed and in readiness for the De La Vergne high-compression oil engines, which will be delivered at an early date.

An average of 60 tons per day is being hauled to the Treasure Mining & Reduction Co.'s mill by wagon. A wire-rope tramway will be built at an early date, saving $1.50 per ton in transportation expense. When the tramway is built, the capacity of the mill will be doubled. The development in the lower levels continues in good ore.

During the week 300 tons of ore were milled at the Deadwood mines, which yielded 20 sacks of concentrate in addition to the gold-silver precipitate. Mine development was advanced 45 ft., opening up new ore. At the Gold Dust Mines property three shifts are advancing adit No. 3, which is 468 ft. lower than adit No. 1, where an oreshoot 530 ft. long has been developed. More than 1000 tons of ore was milled in the seven days by the Socorro Mines Co. The framework for the new power-house is being erected. The working shaft on the Pacific of the Oaks Co. was sunk 7 ft. The workmen's dwelling was completed at the main adit.

Mogollon, October 20.

OREGON

Baker County

The mill of the Blue Mountain M. Co., near Baker, has been set up and tested. Water for the mill is pumped from the shaft. A tramway is being built from No. 3 adit to the mill, a distance of 225 feet.

The season's work of the placer properties on Boulder creek, near Sumpter, has been completed, and all preparations have been made for next summer's run.

Sidney C. Love, formerly of Chicago, owner of the Mormon Boy mine, near Bourne, who was in Spokane a few days ago on the way to Europe, says the property is sending high-grade gold ore to the smelter at Tacoma. He reports that the Ben Harrison and Dixie Meadows, owned by Eastern people, also are in good shape.

UTAH

Kane County

G. T. Holladay, of Salt Lake City, owner of deposits of uranium ore about six miles from Pahreah, is quoted in the press as saying that preparations for mining are being made and that a mill undoubtedly will be erected on his claims.

Salt Lake County

Press reports from Bingham Canyon state that E. A. Wall and J. E. Bamberger have agreed upon terms by which Mr. Wall is to take over 50,000 shares of the Daly West M. Co. at $2 per share. This will give him control and puts an end to reports that the company will be merged with the Ontario Silver Mining Co., adds the report, as he already owns 25,826 shares of the stock issue of 150,000 shares.

The net profit of the Utah Con. Copper Co., taking copper at its present price, for 1911 will be about $300,000, according to an estimate in a report recently sent to stockholders. In the report U. H. Broughton mentions his resignation as president. He recapitulates the development done since the annual meeting in March, and mentions the discovery of two new lead orebodies, and sinking of the 3-compartment shaft from the No. 7 to the No. 11 level and its equipment with an electric hoist.

Summit County

The report of the Daly West M. Co. for the quarter ended September 30 shows cash on hand, after disbursing $54,000 in dividends, amounting to $306,250, making a net gain of $24,009. The orebodies mentioned in the previous report have proved to be persistent. The development work done includes a winze from the 1900-ft. level to the 2100-ft. level for ventilation, safety, and prospecting, and which revealed an orebody supposed to be a continuation of that found at the 1900-ft. level. A drift on the 1700-ft. level, at a point 800 ft. from the shaft, has been in ore of good value for 60 ft. In order to avoid trouble with ranchers, as noted in another column of this issue, the Silver King Coalition M. Co., the Daly-Judge M. Co., and the Daly West M. Co. have jointly bought 700 acres of land for impounding tailing.

WASHINGTON

Ferry County

(Special Correspondence.)—The first two units of the mill of the North Washington Power & Reduction Co. will probably be running on ore by November 10. All of the machinery but two boilers for the power plant has been received and adjusted to its place. The boilers have been shipped and are about due in Republic.

The Hope company has installed a gasoline engine and compressor for four drills at the Black Tail mine. On the 300-ft. level at new drift has been started on the north side of the fault, to pick up the main Black Tail and the cross-vein.

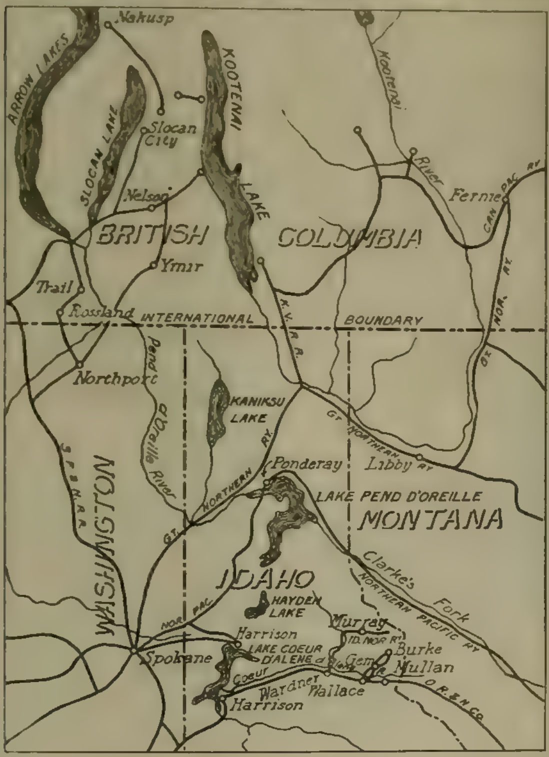
The San Poil Consolidated and Knob Hill companies are planning to join in the construction of a cyanide mill for the San Poil, Trade Dollar, and Knob Hill mines.

Republic, October 23.

CANADA

British Columbia

Jay P. Graves, vice-president and general manager for the Granby Con. M. S. & P. Co., announced on returning to Spokane from New York, that $1,500,000 will be expended in constructing and equipping a 2000-ton smelting plant at Hidden Creek. This includes a tramway, ore crushers, and ore docks at tidewater. Two hundred men are at work on the grading. He also said that the Hidden Creek properties, which have been taken over by the Granby company, will be on a producing basis in a year. Mr. Graves estimates that between 12,000,000 and 20,000,000 tons of ore is in sight at Hidden Creek aand Phoenix. The company has just completed a new plant for disposing of slag at Grand Forks, at a cost of $50,000. The Granby works are practically idle because of the coal miners' strike at Fernie, called last April. The company's coke supply was exhausted in August.



BOUNDARY AND COEUR D'ALENE DISTRICTS.

Ontario

E. Hargraves and W. H. Wright, both of Haileybury, have discovered free gold on their claims in Teck township, Swastika district, according to recent reports from Cobalt. The gold was found in a large dike of quartz and schist.

The Sutherland Cobalt Silver Mines, Ltd., is to continue sinking its shaft, now down 115 ft., to a depth of about 125 or 150 ft. before cutting a station. No change in formation has been found so far in the shaft, which is in conglomerate formation. At the mine there is a small compressor supplying air for two drills. A party of the directors of the company has just completed an inspection of the property.

The quarterly statement of the Temiskaming company says that the diabase sill intrusive into the Keewatin formation, has been found in the west cross-cut on the 575 ft. level, and in the main shaft at a depth of 585 ft. The company had on hand, October 1, $305,547, and a surplus, after deducting wages and taxes payable, of $251,559. The regular quarterly dividend of 3%, amounting to a disbursement of $75,000, was paid October 17.

Free gold has been found on the property of the Boston Development Co., Deloro township, Porcupine district, according to recent press reports.

The Beaver Con. Mines, Ltd., in southeastern Coleman, is to build a concentrator, according to recent reports from Cobalt. The mill will have a capacity of 50 tons per day. The plant will be the sixteenth of its kind in the Cobalt district, assert press despatches. The concentrator is to be in operation by February.

A spectacular showing of free gold has been found on the Brydge claim, in Deloro, Porcupine district, say newspaper reports. The Brydge claim has been purchased by a Klondike miner named Weatherby. It originally was under option to Proctor Smith and associates of New York, but they let the option expire.

A spectacular discovery of ore in a dike of porphyry about 300 ft. wide was made last week on the East Dome claim, according to press reports.

MEXICO

Chihuahua

The report of the Batopilas M. Co. for the year ended Dec. 31, 1910, recently issued, shows that operations were carried on at a loss of $106,258, while the year before there was a profit of $52,782. The shipments of silver amounted to 703 bars, containing 738,730 oz. of silver, against 1027 bars containing 1,047,625 oz. of silver for the previous year. A total of 43,612 tons of ore was treated during the year, against a total of 31,258 tons during 1909. Development work done amounted to 28,908 ft., against 26,491 ft. the year before. On June 30 some of the leased properties were taken over by the Batopilas M. S. & R. Co., a British subsidiary company. Of its 300,000 shares, Batopilas owns 225,000 shares.

The Terrezas smelter of the Rio Tinto Copper Co. will reopen about November 1, according to reports from Chihuahua. About 800 men will be employed. The smelter has been shut down for several months, owing to the unsettled political conditions.

The Chihuahua smelter of the A. S. & R. Co. is to resume operations immediately, according to late reports from Mexico. The present capacity is 650 tons per day. If labor troubles can be avoided two more furnaces will be added to the present equipment.

The new steam-plant at the Apodoquina mine, in the Parral district, is now in commission.

Sonora

Work on sinking the shaft of the Alacran mine of the Moctezumo-Arizpe company was resumed last week. It was about 100 ft. deep when work was stopped several years ago. The mine is one of the Mexican Metals Co.'s properties.

A 20-stamp mill and cyanide plant are being erected at the Oro Colorado mine, south of the Penn Sonora, according to recent reports from Cananea.

A carload of ore shipped to the Copper Queen smelter by the Agua Buena mine is reported to have yielded $4274 net, states a Cananea despatch. C. B. Bell is operating the property.

Rich ore has been discovered at the Penn Sonora property, near Nogales, states C. W. Phillips, who is heavily interested in the mine. The company is to build at Aguascalientes, three miles west from the mine, an electric power-plant for the mine, and a mill may be constructed there, according to recent rumors.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

O. B. PERRY was in San Francisco last week.

HOWARD D. SMITH has returned to San Francisco.

FRANCIS DRAKE sailed for Mazatlan on Monday last.

Inquiry is being made for the address of ERNEST G. LOCKE.

GEORGE H. GARREY has gone to Plumas county, California.

W. J. LORING will sail from New York for London on Tuesday.

VICTOR E. TULL, of Seattle, is at the Palace hotel, San Francisco, for the winter.

R. L. MANN, of Cazadero, was in San Francisco this week on his way to Idaho.

E. C. B. HEDEN is at Southampton, England, having returned from Newfoundland.

ELI T. CONNER has been appointed a delegate to the American Mining Congress held at Chicago.

S. F. SHAW has completed a two months investigation of the Porcupine district, and has returned to New York.

E. R. HAGGIN has accepted the position of chemist for the Cananea Con. Copper Co., at Cananea, Sonora, Mexico.

LEWIS F. JOHNSON has gone to Sierra county on mining business, and expects to return to San Francisco in about a month.

E. R. BUCKLEY has opened an office as consulting mining geologist and engineer at 1364 Peoples Gas building, 122 Michigan avenue, Chicago, Illinois.

FRANK H. PROBERT has left for Ray, Arizona, where he will be engaged in the interests of the Ray Central Copper Co. for the next two or three weeks.

HOWLAND BANCROFT has returned from a five months trip through Chile, Peru, and Bolivia, and will remain in Denver until the first of November, proceeding then to New York.

HERMAN KELLAR is in charge of an inspection trip to Ducktown, Tennessee, by the members of the Board of the Tennessee Copper Co. The party includes RICHARD SUTRO and H. M. KILBORN.

P. B. McDONALD has resigned as assistant engineer for the Munro Iron Mining Co. at Iron River, Michigan, to take charge of exploration work on the Marquette Range for the Heidelbach banking interests of New York. His headquarters will be at Negaunee, Michigan.

GEORGE E. FARISH will succeed CHARLES E. WATSON as manager for the Dobie and Tisdale companies of Porcupine, Mr. Watson having resigned to become identified with Plenaurum. Mr. Farish will assume his new duties on October 31, and will represent the Armstrong-McGibbon interests in the Porcupine district.

Obituary

MALCOLM L. MACDONALD, of Tonopah, Nevada, died suddenly of heart disease on October 23, in New York. He was born at Moundhouse, Nevada, and has been prominently identified with the development of that State. In the protracted litigation between the Amalgamated Copper Co. and F. Augustus Heinze he had a prominent part and later was a leading figure in the early development of Tonopah, where he was associated with T. L. Oddie, George A. Bartlett, W. Brougher, and others. In organizing the First National Bank of Tonopah and the Southern Nevada Telephone & Telegraph Co., as well as in promoting the construction of automobile roads across the desert he contributed materially to the development of the mining industry of his native State.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press.

Mining Monazite—Water Rights

Monazite is found in gravel in beds of streams and adjoining the bottom lands under the top soil. In mining it the top soil must be removed and the gravel thus exposed is shoveled on a perforated steel plate and water is then turned upon it so as to work the smaller material into the trough and the coarser gravel and rock shoveled out and thrown aside. The highest percentage of monazite is obtained by washing several times. The right to mine monazite under a lease of minerals and mineral rights for a fixed period as a stated royalty necessarily involves and carries with it such water rights as are reasonably necessary for the proper conduct of such mining operations, and the performance of such an agreement will be specifically enforced by a court.

National Light & Thorium Co. v. Alexander, (S. C.) 67 Southeastern, 310. March 1910.

Construction of Contract for Sale of Mine

A contract for the sale of a mine provided that before final payment the purchaser should keep constantly employed on the premises not less than four men; and it also provided that on his failure to do so all his rights under the contract should be forfeited, including all tools, machinery, and equipment of every kind on the premises. The purchaser on failure to perform the contract and in anticipation of the forfeiture removed the tools and machinery from the premises and executed a bill of sale for all such property. The subsequent seizure of such tools without the purchaser's consent was held in an action of replevin not to confer such a legal title as to authorize a suit in replevin without demand, as there might be a valid claim to the tools under the contract of sale.

Albright v. Brown, (Ore.) 107 Pacific, 458. Feb. 1910.

Gas and Oil Lease

A gas lease provided that the lessor should have free gas to light and heat his dwelling; and it also provided that the lessee was to furnish the gas on or before a stated date, and that the lessee should have twelve months to drill a well or thereafter pay a certain annual rental until the well was drilled. In an action on the lease the covenant as to the free gas was held to be independent of the covenant as to the time of drilling the well, and that the well must be drilled in a reasonable time and what is a reasonable time was said to be a question of fact and not one of law. It was also held that the lessee could not defend an action for a breach of the covenant on the ground that the lessor had forfeited the lease, as a party will not be permitted to take advantage of his own default and defeat a liability created solely by such default.

Indiana Natural Gas & Oil Co. v. Ganiard (Ind.) 91 Northeastern, 362. March 1910.

Performance of Assessment Work—Contiguous Claims

The statute of California requires $100 assessment work to be performed on mining claims. It also provides that where claims are held in common the work may be done or the money expended on any one claim. A failure to perform the required assessment work renders the ground open for re-location. Under this statute the Supreme Court of California has decided that where several contiguous claims are held in common, the necessary work to keep them all alive may be done on any one of such claims, if the labor or expenditure of money is equal in value to that which would be required on all the claims if they were independent. But such assessment work cannot in any event be treated as a performance of the necessary assessment work on another claim, where the claims are not contiguous in the sense of being attingent, but are separated, as example, by ravine, so that work done on one claim would not naturally benefit or have a tendency to uncover minerals in another claim.

Morgan v. Myers, (Cal.) 113 Pacific, 153. Feb. 1911.

Company Reports

BROKEN HILL SOUTH SILVER MINING COMPANY

This company is capitalized at 200,000 shares of £1 each. The report for the half year ended June 30, 1911, shows that during that period 175,472 tons of ore averaging 14.6% Pb, 6.5 oz. Ag, and 13.6% Zn was produced, and 175,041 tons was milled yielding 26,617 tons of concentrate, containing 71.6% Pb, 23.2 oz. Ag, and 5.2% Zn, and 95,990 tons of zincy tailing, containing 3.7% Pb, 3.8 oz. Ag, and 17.6% Zn. All the zincy tailing and 16,721 tons from the tailing dump was treated by Amalgamated Zinc (De Bavay's), Ltd., and 8991 tons from the tailing dump was treated by the Zinc Corporation, Ltd. The operating costs were as follows:

	s.	d.
Mining	10	8.6
Filling stopes	1	7.7
Development	1	3.0
Concentration	3	6.4
	17	1.7

The operating cost for the preceding six months was 16s. 2.8d., the increase being chiefly due to a 10% increase in wages which took effect January 1, 1911. The yield from the mine was £209,113, and from sale of tailing £41,945, a total of £251,058. The cost of mining was £108,193; concentration, £30,888; exploration and development, £10,948; freight and commission, £17,673; general charges, £1096; balance to profit and loss account, £82,260. Dividend 47 and 48, amounting to £60,000, were paid; £5087 was written off as depreciation on plant; £5090 was paid for office expenses, taxes, royalties, and other general items, leaving a balance on hand of £66,000. The property of the company consists of 69 acres, Block 7 and 8, at Broken Hill, New South Wales. The main shaft has a depth of 1150 ft., the milling plant has a capacity of 1500 tons per day. The Zinc Corporation has a contract for the accumulated tailing at 3s. 10d. per ton, and Amalgamated Zinc (De Bavay's), Ltd., has a seven-year contract for the current tailing at 3s. 9d. per ton. The shares were quoted in London on September 15 at 6$^5/_{16}$ to 6½.

CONSOLIDATED MERCUR GOLD MINES COMPANY

This company, which has been operating mines at Mercur, Utah, is capitalized at 1,000,000 shares of $1 each. During the year ended June 30, a total of 239,190 tons of ore was treated, from which an average recovery of $2.32 per ton was made, at a cost of $1.29 per ton for mining and $1.04 per ton for milling, a total of $2.33. The average content of the tailing was $0.88 per ton. The itemized treatment costs are as follows:

	Per ton.
Crushing	$0.1082
Roasting	0.9201
Leaching	0.4687
Precipitating	0.0532
Refining	0.0419

The operating loss was converted into a small profit by miscellaneous sources of income. During the year bullion to the value of $550,696 was produced; miscellaneous receipts amounted to $7933. The total cost of mining was $310,110; milling, $247,974, and $49 for the Manning mill, leaving a net profit on the year's operations of $496. During the year 5558 ft. of prospecting work was done at a cost of $4.40 per foot, but the results were disappointing. Several of the stopes are now practically exhausted, and the end of the life of the mine is obviously near. The management is endeavoring to acquire a new property, in order that the company may continue its existence.

Utah Consolidated has declared a dividend of 50c. per share, the first paid since January 1910. The resignation of Urban H. Broughton was accepted at the meeting. Roscoe H. Channing is the present general manager.

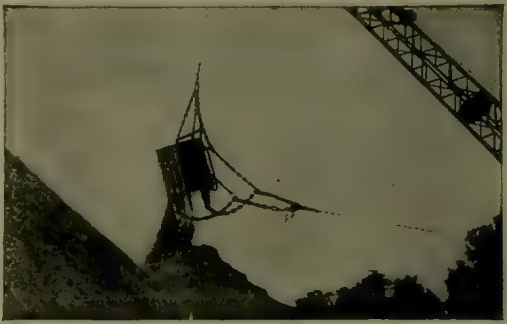
Hayward Drag-Scraper Bucket

The Hayward Company, manufacturers of the well known Hayward orange-peel and clam-shell buckets, has recently added a bucket of the drag-scraper type to its line. This bucket and its method of operation are easily seen in the accompanying illustration. It has been developed under the personal supervision of Judson Hayward, who conducted a long series of experiments under actual operating conditions, and the manufacturers claim that the new bucket is superior to others intended for like work, by reason of the greater speed with which it may be operated, greater capacity per single operation, and the ability of the bucket to work equally well in soft and hard material. It is said that it takes two men less than three minutes to change this bucket from a hard-digging bucket to a soft-digging bucket.



DRAG-SCRAPER BUCKET DUMPING IN VERTICAL POSITION.

In the mining field, the new drag-scraper bucket will be found particularly useful in placer mining, where the area of the property is so limited as to prohibit the economic use of a dredge of the California type. Inasmuch as a careful study of the conditions surrounding placer mining contributed to a considerable degree to the design of the drag-scraper bucket, careful attention having been paid to the work of machines heretofore employed in this work, the Hayward Company feels confident that it is now offering a type of bucket peculiarly well suited to placer mining. The digging and suspended mechanism, together with the arrangement for discharging the load, are positive in action, and the control of the bucket in a manner which insures great capacity is therefore possible even with a comparatively inexperienced operator.

Ernst Wiener Co., 46 Church St., New York. 'Carrying the Burdens of the World,' describing its line of cars, barrows, etc. 8 pages. Illustrated. 6 by 9 inches.

The Watt Mining Car Wheel Co., Barnesville, Ohio. Catalogue G, 'Ore Buckets and Skips.' 8 pages. Illustrated. 5½ by 8 inches. Catalogue H, 'Mine Car Wheels and Axles.' 16 pages. Illustrated. 5½ by 8 inches.

Denver Fire Clay Co., Denver, Colo. Bulletin No. 41. 'Case Gas Furnaces, Etc.' 16 pages. Illustrated. 4¾ by 7¼ inches. Also pamphlet, 'The Donaldson Tilting Crucible Furnace.' 6 pages. Illustrated. 3½ by 6¼ inches.

Edwin Yawger, Denver district manager for the Westinghouse Machine Co., read an interesting paper on 'Condensers and Cooling Towers' before the ninth annual convention of the Colorado Electric Light, Power, and Railway Association, at Glenwood Springs, recently. The article has been printed in pamphlet form.

EDITORIAL

BULLION is becoming popular in financial exchange and nearly half a billion dollars in this form is now stored at the Denver Mint.

LENDING money to Europe, though not an unprecedented action for the United States, is at least unusual enough to deserve attention, and $10,000,000 in Prussian Government notes is not a small sum.

THE son of Charles Dickens has come to America to lecture upon his father's works and personality, and if he receive a welcome from every lover of the creator of *Mr. Pickwick*, *Agnes Copperfield*, *Mrs. Wilfer*, and *Nicholas Nickleby*, his ovation will be a hearty one indeed.

COMPLAINT has been made that the New York Edison Company has been furnishing power at a wholesale rate below the cost of production, the rate charged the small consumer amply repaying the deficit. This is one of the causes of popular demand for the regulation and control of public service corporations.

IN OUR issue of October 14 we quoted from *The Cement Age* a description of a battery foundation, which was there credited to Mr. F. E. Perkins. We are now informed that this article was actually written by Mr. F. E. Shepard, the president of the Denver Engineering Works Company, and are glad to bestow credit where much credit is due.

JOHN MARSHALL HARLAN, late justice of the Supreme Court of the United States, was a notable figure in many ways. Appointed to the Supreme Bench in 1877, his acts throughout his long term of service exhibited a man as big in mind and soul as he was in physique. Simple and kindly in tastes, staunch and uncompromising in intellect, hater of injustice and oppression, he was of the type of man which the Nation can ill afford to lose.

INDIANA held a conservation congress last week at the call of the governor, Thomas R. Marshall. Many notable speakers addressed the gathering, and permanent committees upon soil, natural resources, water and waterways, forestry, and vital statistics were appointed. The arousing of intelligent public interest in these vital problems of community life must result in great benefit to the body politic, and the precedent set by the Hoosier State should be followed by others.

OFFICIALS of the American Mining Congress were elected at the meeting in Chicago last week, and Mr. S. A. Taylor will be the new president, Mr. D. W. Brunton being first vice-president, and Messrs. E. A. Montgomery and Carl Scholz being the second and third, respectively. Mr. J. F. Callbreath, who has done such notable work in the upbuilding of the Congress, remains as secretary. The meeting was a notable one, both in the list of speakers and in the interest aroused, and on another page we give two of the more important papers of the session, which will be of interest to our readers.

MINE SAFETY was the subject of a demonstration by the Bureau of Mines at Pittsburg, on Monday and Tuesday of this week. The first day was occupied with demonstrations of explosives, safety lamps, and fuel testing, and on the following day visiting teams competed in first aid and mine rescue work. President W. H. Taft presented the prizes to the winning teams, and much interest was aroused.

POWER of things seen, as compared with things unseen will be utilized in the special train which will leave St. Louis on November 17 for an extended tour through Eastern States. The governors of California, Colorado, Idaho, Montana, Nebraska, Oregon, Utah, Washington, and Wyoming will be attended by exhibits of the agricultural and mineral products and wealth of their respective States. California will have double space, in order that the Panama-Pacific Exposition of 1915 may be adequately represented. Aside from the advertising value to the States represented, the plan of sending peripatetic exhibits to the East is one of great educative value, and should be warmly commended.

PERPETUAL restrictions often prove in the end a source of disadvantage. Sailors Snug Harbor, in New York City, owns real estate worth $21,500,000, a bequest made over one hundred years ago with the restriction that the land could never be sold. The trustees, overwhelmed with their holdings, are now endeavoring to devise a method by which the will may be broken and the property sold, so that more remunerative investments may be made. To foresee all the future is impossible, and here may be seen one of the disadvantages of a constitutional form of government, as compared with a monarchy. With new centuries come new kings and emperors, who are reasonably up to date; a constitution persists, even though the form of society which it was framed to govern has changed beyond all recognition.

THE Colorado Scientific Society has recently, in conjunction with the State School of Mines at Golden, arranged for a series of joint meetings in the larger mining towns of the State, for the purpose of awakening among miners a keener interest in the technology of mining. The application of sound business methods to mining and the increasing of the efficiency of metallurgical processes are the chief topics under discussion, and the movement deserves to meet instant success. The outcome will be awaited with interest, for the problem of retaining the attention of 'practical men' is a difficult one whenever discussions advance beyond topics of immediate usefulness. Since the days when Emmons, Van Diest, and Richard Pearce, to name but a few, made the meetings of the Colorado Scientific Society notable it has made a record of achievement, and we rejoice in this new evidence of service to the interests of the profession.

ELSEWHERE in this issue Mr. H. J. Stevens gives interesting data upon the past, present, and future of the copper industry, which will be of much interest to many. Extrapolation is at best a hazardous method of computation, however, and is subject to the error incurred by the proud young father who announced that his three months old son was the finest boy that ever existed, for if he kept on growing at his initial rate he would, at the age of 21, be fifteen feet tall and weigh six hundred pounds. Mr. Stevens concludes with a review of the copper mines of Alaska, discussing them from the business standpoint, and writers for the popular magazines will profit from its perusal. It is interesting to note, in passing, that in a thoughtful article on the Bering river coal-field, in the November *Popular Science Monthly*, Mr. G. W. Kay, professor of geology in the University of Iowa, similarly concludes that, so far as this part of Alaska is concerned the coal resources have been greatly overestimated.

CHINA continues to hold the forefront of public attention, and rightly so, for the changes which are taking place in that huge country are of world-wide importance as well as interest. The most notable development of the week has been the demand of the National Assembly for the immediate institution of a constitutional form of government, and the support of these demands by the army, now under the command of its old leader and creator, Yuan Shih-kai. It now seems certain that the Manchu officials must go, and with them the Chinese officials who, like Shêng Hsuan-huai, have been identified with the program of foreign loans that has incurred popular disapproval. The institution of a republican form of government in China is both improbable and unnecessary, as in constitutional monarchies, such as Great Britain, the will of the people finds quite as free exercise as in republics, such as our own. Meanwhile the fighting between the insurgent and imperialist forces is sharp, with heavy losses on both sides, emphasizing the fact that this is no opera bouffe revolution.

THE seamy side of mining finance has been in evidence in New York this week. In the Federal courts, a judge and jury are trying to unravel the devious methods of George Graham Rice and his adventures with other people's money. Rice has been exposed time and again, and his history has repeatedly been printed in the papers of the large cities. Though a clever and unscrupulous student of human nature, he is erratic and in times of prosperity suffers from an exaggerated ego. In another instance of criminal investigation there is some cause for sympathy. For some months there has been a great deal of comment concerning the promotions of a certain Albert Freeman, who in some way managed to associate with himself Julian Hawthorne, son of Nathaniel Hawthorne, the noted novelist. The younger Hawthorne had already made for himself a name in the world of letters, when he unfortunately turned his pen to the task of preparing glittering prospectuses and letters offering mining shares for sale. Josiah Quincy, ex-mayor of Boston, was an associate of Freeman in these ventures, another being J. B. Hanna, a nephew of the late Mark A. Hanna of Cleveland, Ohio. Nothing could have less to do with the real industry of mining than the operations of such gentry, and it is unfortunate that the legitimate industry should suffer as it does from such promotion jobbery, or that so-called mining ventures should be so frequently used as lure for the unwary, the avaricious, and the overtrustful.

Filling Mine Stopes

Filling of mine stopes is given added present interest by the recent caving in of the stopes of the App mine, in Tuolumne county, California. The damage in this case seems to have been small, owing to the absence of surface improvements in the area affected. But where mine workings underlie towns and other works of man the problem often becomes a serious one. Where timber is employed the cost is great where the ground is heavy and, in addition, as in this case, there soon comes a time when the decay of timbers is so far advanced that they can no longer perform their duty. If the ground yields slowly, swelling as it breaks, all may be well, especially if the workings are so deep seated that the disturbance does not extend to the surface. The filling of excavations with rock may be practised, but is expensive and open to the objection that the shrinkage is considerable where the volume of the stopes is great. In coal mining culm is often used for this purpose, and in the October issue of *The Mining Magazine* Mr. Edgar Pam describes the filling of workings with sand and gravel, which can be transported by water and exhibits a comparatively slight shrinkage. This method is attracting much attention upon the Rand, and is worthy of attention here. At the La Belliere, at St. Pierre Montlimart, in France, the sand from the cyanide plant is flushed into the stopes, at once serving as filling and solving the problem of securing sufficient storage room for tailing, a method that could easily be imitated at other mines. If no other purpose than the conservation of the dwindling supply of timber were served by the more general use of filling methods, their development would be amply worth while, to which safety from mine fires and cave-ins lend an additional advantage.

Industrial Unrest

At the close of a long civic struggle that marked an epoch in our national development the sentiment of the Nation was voiced by a great leader when he said, "Let us have peace." After years of industrial unrest in which efforts, in response to a popular demand that enterprises which directly affect the prosperity and safety of the entire body politic be subject to public scrutiny and control, have exhibited themselves at least as notably in the hampering of development as in the attainment of useful results, we are again nearing a state of mind where both the regulators and the regulated are becoming desirous of peace rather than a continual struggle. That changes, and important changes, are necessary cannot be gainsaid. Once during the Civil War General U. S. Grant is said to have desired to move his army across a river, and calling to him one of his engineer corps, a bridgebuilder of long practical experience, directed him to obtain working plans from the chief of the engineering staff and to construct the bridges as rapidly as possible. Later in the day, seeing the engineer approaching, he inquired what progress was being made in the preparation of plans. "General," was the reply, "the bridges are done; I don't know whether the pictures are or not." The enormous amount of rapid work that has been done in the industrial development of America in the last half-century has made necessary the not waiting for pictures in many cases, with the inevitable result that much has been done which will not meet the final specifications, nor does it all join into one harmonious whole.

Industrial evolution has now ushered in an era of operation of large units to secure economic efficiency, bringing new problems in its train. A 30 horse-power motor-car can be started and stopped at will, and if it is often necessary to adjust and repair it the individual owner is more annoyed than seriously discommoded. But a 3000 horse-power gas engine, which furnishes the electric energy to light a whole city, is a different affair. If adjustments and repairs are necessary, not one but many are affected; the aggregate discomfort and inconvenience forms a total which must be seriously considered. In the mechanical world a comparatively simple solution is available—duplication of machinery makes alteration and adjustment easy. In the economic world we have no such simple recourse; we cannot obtain our twenty-five million tons of steel products elsewhere while the Steel Corporation is being taken apart and reconstructed in accordance with what are the ideas of the moment. Every consideration calls for haste in the repair and readjustment of the industrial-social organization, yet the problems involved are so little understood that there is little consensus of opinion as to their proper solution. The suggestion is made that we need successful business men as legislators, to which the reply is that most of our present difficulties are due to the fact that so many of our legislators already are the covert or avowed representatives of business interests. We have had in the past too much individualism in our social development. The cure for this is not Socialism, but enlightened individualism—less of individualism and more of enlightenment.

The Market Value of Knowledge

For some months past the discussion columns of contemporary journals devoted to civil engineering have contained letters complaining of the low salaries paid to surveyors and civil engineers engaged in similar lines of work. The correspondents appear to believe this an abnormal and adventitious state of affairs, and are loud in their complaints. Yet nothing seems more obvious than that the ordinary laws of supply and demand are applicable; the low salaries paid to surveyors are due to the fact that a sufficient supply of capable men can be obtained at the rate of payment now in force. In the comment made upon the situation two important points seem to have been overlooked. One of these is that the average graduate of a technical school is, immediately upon graduation, incapable of performing most of the duties of engineering work without a preliminary period of training. Surveying is one thing which he can do satisfactorily, providing he has received his college training at any one of a large number of efficient schools. As a result the post of surveyor is the accepted starting point of the young engineer in the larger number of cases. The supply is therefore ample, the demand limited; the result follows naturally. The second point is one that is often overlooked and is frequently the cause of the belief by a young engineer that his merits go unappreciated. It is a fact that the mere possession of knowledge has little earning capacity, only skill in the application of knowledge to the attainment of some useful purpose has earning power, because it is from such application that useful results flow. To put it briefly, the manager draws the large salary because he makes or mars the profits of the enterprise. The horses furnish the strength and speed to haul a dray and receive their board and keep; the man who hitches them in their proper position and guides their efforts in the proper direction receives a wage. The simile is a crude one, but it cannot be denied that knowledge is only the 'basement complex' in which the rich veins of responsibility, initiative, and insight occur, from which golden dividends are won. Complaint is often made that there are few technical men at the head of large enterprises, but nothing is more certain than that if technical men as a class exhibited notable ability in the management of large enterprises their services would be in urgent demand. Frequently men have attained distinction in one branch of knowledge by ignoring the claims of everything outside the circle of their interest. The head of a large enterprise becomes perforce a clearing-house of knowledge, rather than a treasury of information; the demands made upon him are so various that he must of necessity rely upon others as sources of information; only the sifting, collating, and transmuting into useful form are his province. For a comparatively small sum the latest revision of the Encyclopedia Britannica can be secured, and special books of reference are equally available. Such being the case, the human encyclopedia can scarcely expect to receive a princely salary. On any subject there are available scores of men competent to collect data; the man who can see straight through the mass to the essential fact and set it in its right relations is the man who produces results and is rewarded accordingly.

Brazil as a Field for the Prospector

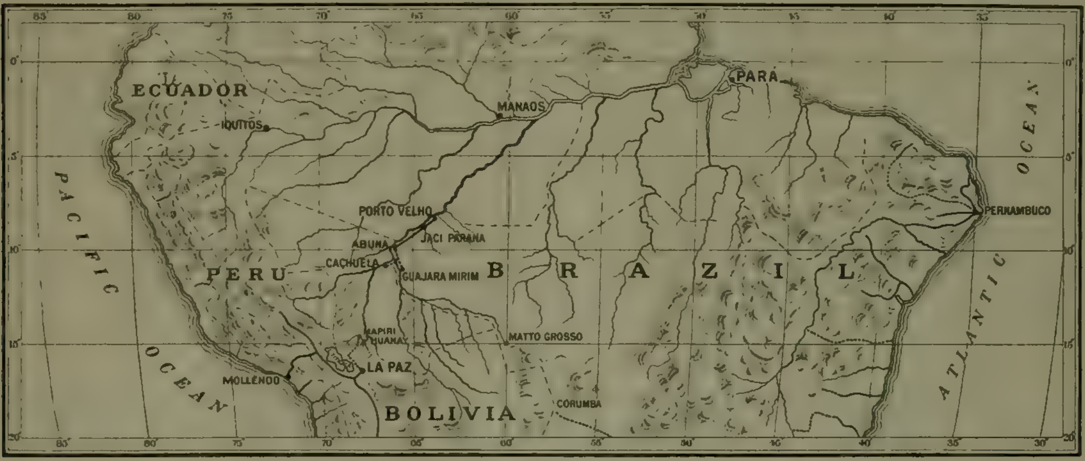
By Alexander P. Rogers

South America was a fruitful field for the early Spanish adventurers. Their cupidity drove them forward with a superhuman zeal to make most astounding trips in the quest for gold through a tropical country which was fairly bristling with all kinds of dangers. To one who ventures in those regions today it comes as a revelation to be confronted every now and then by the evidences of their travel, and you wonder how they ever had the courage to attempt such trips two and three hundred years ago. I am referring especially to the region lying upon the eastern slope of the Andes in Bolivia and Peru. The famous wealth of the Incas is supposed to have come from there, and at the present day the old ditches are still visible in certain places. To the average man this is a *terra incognita*, and few mining engineers are much more familiar with it.

Although the existence of gold has been known for a long time in this locality, the great difficulty of entering the country has deterred most people from making any attempt to look for it. In recent years it has been possible to go to La Paz and the Lake Titicaca region by rail, and several adventurous mining companies have even pushed on over the main range of the Andes to the eastern slope and erected dredges upon some of these rivers. The cost of transportation, however, is almost prohibitive, and the extremes of altitude and climate to be met are enough to lay the average man low in short order. A mine must be in the bonanza class to stand the strain. For these various reasons, the country has been very little explored to date.

Now, however, a route is being opened which should offer a great stimulus to exploration in this field. Most of the rivers upon the eastern slope of the Andes flow into the Amazon sooner or later. In the region in question they first flow into the Beni, which flows into the Madeira, and that river empties into the Amazon, forming an extensive river system through an enormous tropical jungle; but the point which is not generally understood is that this river system is largely navigable throughout the year. Ocean steamers from Europe and America go right up the Amazon to the city of Manáos—a distance of 980 miles from Pará—and many of them go up the Madeira river, 700 miles beyond. From that point a series of rapids extends upstream for 220 miles before navigable waters are again met. Above these rapids, however, the Beni, Mamoré, and Guaporé rivers are navigable another thousand miles for light-draft river steamers; in fact, steamers have been in operation here for many years; but the rapids upon the Madeira have presented a serious obstacle to intercommunication between the two sections.

Realizing this fact, the Brazilian Government undertook to build a railroad around this point. Their first attempt was a failure, but later on they secured powerful financial help and experienced American contractors, with the result that the line is now nearing successful completion. This road ranks with the Panama railroad as one of the great works of man. To the casual observer who travels over its 220 miles in a comfortable coach, this statement may appear unfounded, as he cannot realize the difficulties which had to be overcome, nor does he know what it has cost in human life. They say at Panama that for every tie in the railroad a life was lost. Upon the Madeira-Mamoré railroad this would also have been true, except for the fact that an enormous sum was spent, and is still being spent, upon the most up-to-date sanitary arrangements. It reminds one of the sanitation along the Panama Canal upon a smaller scale. At the time the work was started the death rate from fever and other tropical diseases was appalling. Out of the first 52 men sent to work on the line, 49 died in a short time, and later on when fever again broke out, the whole force became panic-stricken. By a lavish expenditure of money, a system of sanitation was established which has been steadily developed, until today there is a minimum amount of sickness and the end of the great work is close at hand.

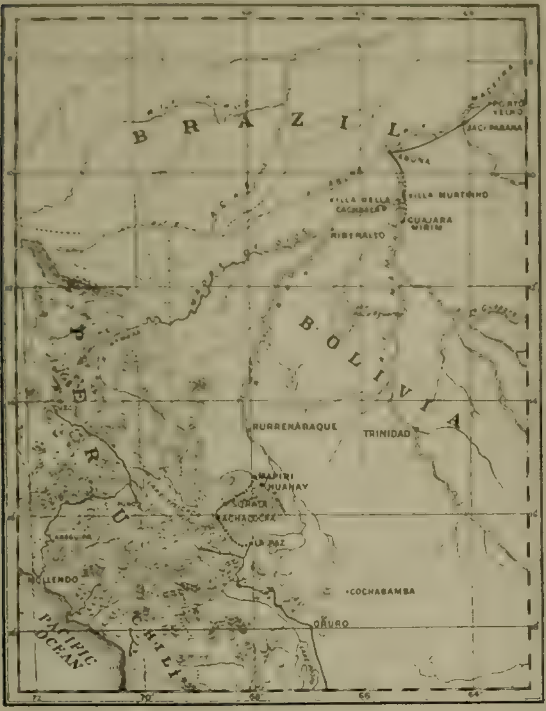


CENTRAL SOUTH AMERICA.

As already mentioned, the road is approximately 220 miles in length, starting from a point on the Madeira river, called Porto Velho, which large ocean steamers touch during most of the year. The upper terminus is at Guajara-Mirim upon the Rio Mamoré, where river steamers can be taken for 1000 miles up the Mamoré or Guaporé rivers. From a place called Villa Murtinho, a branch line crosses the Mamoré and goes to Cachuela on the Rio Beni, at the head of the rapids, where steamers belonging to the railroad company can be taken upstream for seven or eight hundred miles to Rurrenabaque. This is a pleasantly situated little town, about 1000 ft. above sea-level. You are still 100 miles below Huanay, in the gold country at the foot of the mountains, but this is as far as the steamers can go, and rafts must be resorted to beyond.

Just above Cachuela the Rio Madre de Dios empties into the Beni. Another line of steamers run up this river to the Inambari, which is known to contain considerable gold. In fact, a dredge has been installed and is working there now. By reference to a map of South America, it will be seen what a tremendous region is opened up to the prospector. Let no one imagine, however, that it is a playground, because it is not.

The railroad and river steamers have smoothed out the most dangerous and unhealthy places along the line, and have solved the question of transportation as far as they go, but beyond those points it is still rough sledding. It is no worse, however, than the pioneers encountered in going to the Klondike, and there is no extreme cold down here. Perhaps that may not be considered a great inducement to enter the country, but good mines are not found on every hill and the world has been so much explored already that it is necessary to go to these out of the way places in order to find new ones. Until some are found, there is no inducement to the transportation companies to extend their communications farther afield. What they have done is to offer a new point of attack, which cuts down the cost of transportation to more reasonable limits and avoids the necessity of hauling supplies over the tremendous altitudes of the Andes. Up to the present time all freight brought to Rurrenabaque has been much more expensive than that hauled from the Pacific over the mountains to Mapiri or Huanay. With the advent of the Madeira-Mamoré railroad and its system of river steamers, these costs will be reversed, and it remains for the prospector to find the mines before the railroad can be induced to push forward local means of communication. I believe, however, that the railroad would assist any legitimate undertaking throughout the region. A short account of a trip taken from La Paz over the mountains and down the Beni may be of interest to explain the difficulties encountered by travelers.



MAP OF PART OF BOLIVIA.

La Paz lies at an altitude of 12,000 ft. From that city a good wagon-road extends to Achacocha on the eastern shore of Lake Titicaca—a distance of 110 kilometres. From Achacocha to Sorata, the journey must be made on muleback over a rough trail between 35 and 40 kilometres in length. Beyond Sorata the trail crosses the main range of the Andes at an altitude of over 17,000 ft., and then drops down by a series of steep descents to the small settlement of Mapiri, only 2000 ft. above sea-level. It takes four days of strenuous effort to cover this distance of 160 kilometres, camping out each night wherever you may happen to be, but the experience can only be fully appreciated by actually making the trip. Once arrived at Mapiri, the mules are discarded and travel by raft is resorted to.

From Mapiri to Huanay is 60 miles by the river, or one and one-half days travel on a raft, and from there to Rurrenabaque, a distance of 100 miles, requires six days more over a series of rapids and through canyons, where the dangers are largely dependent upon the season. The best time of year to travel over this section is between July and November, when the river is low. After November it becomes very dangerous on account of the heavy rains. The cost of hauling in freight over the Andes is necessarily high, as everything must be sectionalized and carried on muleback.

In contrast to this journey, the route from the Atlantic, by way of the Amazon river, presents a marked advantage in the cost of transportation. It will take somewhat longer, but that is unimportant where freighting costs are in question. From Pará to Porto Velho is a trip of eight or ten days, depending upon the steamers. Traveling over the Madeira-Mamoré railway to the Cachuela on the Rio Beni will take another day, and up the Beni to Rurrenabaque about a week more, when the regular service has been inaugurated; probably before the end of the year, as the steamers are now being built on the river. From Rurrenabaque to the gold country about Huanay and Mapiri the trip is made on rafts, which are hauled up over the rapids. It is slow work, but pieces of freight weighing as much as five tons can be transported in this manner, an impossibility over the Andes. To enter the Inambari country, by way of either Tirapata or up the Amazon, will require about the same length of time.

At Mapiri there is some fever, but this country as a rule is not afflicted by the bad fevers found upon the lower Amazon. Anyone going in there, however, should carry a folding bed and finely woven mosquito net, as well as a plentiful supply of quinine, bismuth, and other necessary medicines. These things, as well as canned food and prospectors' outfits, can be purchased at Rurrenabaque. It must also be understood that the country is difficult to prospect on account of the dense tropical jungle covering everything, but the small rivers are numerous and the best opportunities at present will be found in placer deposits suitable for dredging or hydraulic purposes upon the borders of these streams. There is a vast region here awaiting hardy pioneers, which has been lying untouched for years, simply because it could not be easily reached. The point of this article is to draw attention to the fact that a short stretch of railroad along the Madeira river on the western boundary of Brazil has changed these conditions to such an extent, and will change them still more in the future, that a new field has practically been opened to the prospector.

Rediscovery of Lost Mines

An account of the rediscovery of certain lost emerald mines in Colombia is given by Douglas B. Sterrett in an advance chapter from the 'Mineral Resources of the United States.' When the Spanish took possession of that country in the sixteenth century the emerald mines of the Indians were seized by them. Excessive cruelties were practised by the Spanish mine workers on the Indians employed in the mines. In the war of independence of 1816 the country was so desolated that the mines of Cosquez and Somondoco were entirely lost. A Colombian named Francisco Restrep, guided by a few hints given in ancient Spanish parchment maps, and with little or no knowledge of geology or emeralds, undertook the search for the lost emerald mines. In 1896 he found traces of ancient workings and later the large workings of the lost mines. These mines are situated on a ridge of the great eastern range of the Andes, at an elevation of about 9000 ft. above sea-level. The great open-cuts and tunnels were scattered over an area 6 miles long and 3 miles wide. Some of the working faces of these mines measure 700 to 800 metres on steep slopes; of this, about 100 metres is emerald-bearing and the rest non-productive.

The Valuation of Oil Lands

By William Forstner

Among the several problems which a consulting engineer has to solve when examining an oil property, that of a proper valuation of the property, which will afford a basis for its financing, is undoubtedly one of the most difficult. The same question is considered one of the most important in examining a mining property, and in the case of oil properties the difficulties are much greater. In recent issues of *The Mining Magaine* M. H. Burnham has presented a series of articles bearing on 'The Finance of a Mine,' and I shall try to apply his ideas as far as possible to oil properties.

Mr. Burnham bases the capitalization of a mining property upon the rule that: "The requirements from the yearly return on capital invested in any undertaking with a terminable life are, that a portion be set aside to redeem the capital, another to provide such interest as is paid by Consols, and a third to meet the risk of loss. Expressed in simplest algebra this may be written:

[1]$D = r' + r'' + r'''$."

For American conditions these terms would express: D, the yearly net profit; r', the general rate of interest on money invested in high-class securities; r'', the yearly contribution for capital redemption purposes; r''', the portion set aside to meet the risk of loss of either capital or interest.

In estimating the value of mines, r' and r'' are covered by the net profit on the ore actually blocked out in the mine, in the case of gold ores, a known quantity, while in the case of other metals the value of the product must be conservatively estimated according to its market value and the general market conditions at the time, and the variations in its selling value must be included in determining the risk rate r'''. In estimating the value of an oil property the known factor is missing, or only exists to a small extent. Oil properties may be subdivided into the following eight classes:

Class 1: *Properties with producing wells and surrounded by producing properties.* Here we have the most favorable conditions to deduce a valuation. The value of an oil property consists in the profit that can be obtained by extracting the oil existing beneath its surface. This profit depends upon: the amount of oil which can be extracted; the outlay required to extract and market this oil; and the market value of the oil at the time of the sale thereof.

The amount of oil which can be extracted from a given territory can at the best only be approximately estimated. The oil-bearing parts of the underlying strata occur in lenses, which vary greatly in size, and are not of regular thickness. Besides, the degree of coarseness of the granules forming the material wherein the oil accumulates varies considerably in most of the lenses, as is proved by the microscopical study of the oil sands in neighboring wells. The degree of cementation in each individual lens also varies. The degree of saturation of the oil-bearing material is then a constantly varying factor. The pressure under which the oil exists is also variable, especially in those fields where the oil contains occluded gas. When we further consider that the production of a well is greatly influenced by slight imperfections either in drilling or completing the well, which may cause interrupted access of the oil to the sump which forms at its intake, it is clear that the production of each individual well, even within the restricted area of a property, is a variable factor. For instance, take the records of three properties, one in the Kern River field, one in the Coalinga field, and one in the Sunset field. In the first, covering 160 acres, the thickness of the oil sands varies from 95 to 404 ft.; the monthly output varies 26%. In the second, covering an entire section, the thickness of the oil sands varies from 110 to 547 ft., and the daily production per well from 20 to 636 bbl.; neither is the production of each individual well constant; it varies in some extreme cases 70%. In the third, covering 160 acres, the thickness of the producing oil sands varies from 32 to 247 ft., and the monthly production varies 33%. These figures show how irregular the production is on individual properties.

As to larger areas, for the year ended June 30, 1911, the daily average production of the wells, taken month per month in the different fields of the State, vary as follows:

Field.	Highest month, bbl.	Lowest month, bbl.	Per cent of highest.
Kern River	26.6	24.4	93.8
Coalinga	84.2	64.5	76.6
McKittrick	96.0	75.4	78.5
Midway	207.1	122.6	59.2
Santa Maria-Cat Canyon	185.6	119.6	64.4
Salt Lake-Sherman	38.1	29.1	76.4
Whittier-Coyote	24.9	18.4	73.9
Fullerton-Brea Canyon	75.8	45.7	60.3

I do not include the Sunset district in this list because its production during the last six months of the year 1910 included the shipment of the oil from the Lakeview well accumulated in the prior months. The figures for the Coalinga field are influenced by the very high production of the month of July 1910, and the extraordinarily low production during February 1911, which latter was due to the destruction of the pipe-lines caused by heavy storms. Eliminating these two months the figures would be:

Highest month, 79.4;

Lowest month, 68.2; 85.9% of the highest month.

In the Santa Maria-Cat Canyon field I eliminated the month of June 1911, because the production of that month was abnormally low, due to the sanding up of the Palmer wells, which had been temporarily suspended as the storage capacity of the company was filled with surplus oil. The above table shows that the average daily production per well in the different fields varies very largely except in the Kern River field, where it remains remarkably steady.

The only way to arrive at a satisfactory estimate of the production is to study the conditions of production and the behavior of the different wells on the property, and on those surrounding it, the conditions of the underground water, and other factors, and to base upon these data an estimate of the daily average production. The net profit to be derived from the sale of the oil will depend upon the market value of the oil and the cost of its production. The former is again to a large extent a matter of estimate, depending upon the future condition of the market. The probable minimum price for the next year will be a safe estimate, and the risk of a drop in the price will have to be taken into account when determining the value of r'''.[2] If the books of the company operating the property are well kept, the cost of production can readily be ascertained. This item includes only the care of the producing wells and their repair, the cost of handling the product, and general expenses, but does not include new development work. Unless some of the wells are in bad shape, and will require considerable work, perhaps redrilling, the cost of production can be closely estimated. In this manner we arrive at the figure of the net returns from the actually developed resources of the property.

The operation of an oil property consists in the extraction of the resources therein contained, and in most cases after these are extracted the value of the property may be considered zero. It is therefore necessary to provide for an amortization fund, which at the time of the depletion of the oil resources will at least equal the amount originally invested. The length of time within which the resources of the property will be exhausted determines then the value to be assigned to r″. Here the engineer meets another difficulty. Oil development in California is of too recent date to furnish reliable data in regard to the longevity of the wells in the different fields, and more so in the different portions of each field. In the Kern River field wells 11 years old are still producing, at a rate indicating but a slight yearly decrease in the production. In the Coalinga field, wells 10 years old are still producers; and in Los Angeles and Ventura counties older wells are still active, but the latter are small producers. Assuming, as is generally the case, that the property is only partly developed, it will be safe to allow it a productive life of 15 years, and assuming the rate of interest at 5%, then figuring at compound interest, a yearly sum equal to 4½% of the investment will at the expiration of that time refund that investment.

[2] *Loc. cit.*, p. 362.

The risks incurred in the fluctuations of the market value of the oil, and the risks of loss either in capital or interest to be taken in the operation of the property are combined in the terms r‴. The market value of the oil depends on so many conditions influencing the relation of production to consumption, that it is impossible to predict the course of its fluctuations with sufficient certainty to allow anything but an approximate value to the term representing that risk. The influence of the fluctuation of the market value on the net profits depends upon the relation of the value of the oil to the cost of production. For instance, considering the reduction in the prices paid by the Standard Oil Co. made a few months ago, from 65 to 45c. per barrel for oil above 22° B., and from 50 to 30c. per barrel for oil below 22° B. Assuming the cost of production at 10c. per barrel, this meant for the high-grade oil a reduction of profit from 55 to 35c. per barrel, or of 36.4%, and for the lower-grade oil from 40 to 20c. per barrel, or 50%, although in each case the reduction was 20c. per barrel. The engineer will have to give his term a value based on his conception of the existing conditions, and those he considers most probable to arise in the future. In my opinion, from 3 to 5 will cover the different cases.

The risk of loss either in capital or interest during future operations depends largely on the conditions of the oil occurrence in the territory within which the property is situated. In some parts of the California oilfields these conditions are very regular, so that the wells can be kept on production at little expense. In other parts water has invaded the oil sands, or may be expected to do so within a short time, and will cause great expense, and may materially affect the production of the wells. In other parts the character of the oil sands and the heavy gas pressure in the oil measures render the production of the wells irregular, necessitating a great amount of repair on the wells, often requiring them to be redrilled, and sometimes to be abandoned; and in the case of new wells causing them to be failures, or to cost an excessive amount of money. The value to be allowed for this portion of the term r‴ varies, then, within wide limits; which I suggest as from 3 to 10.

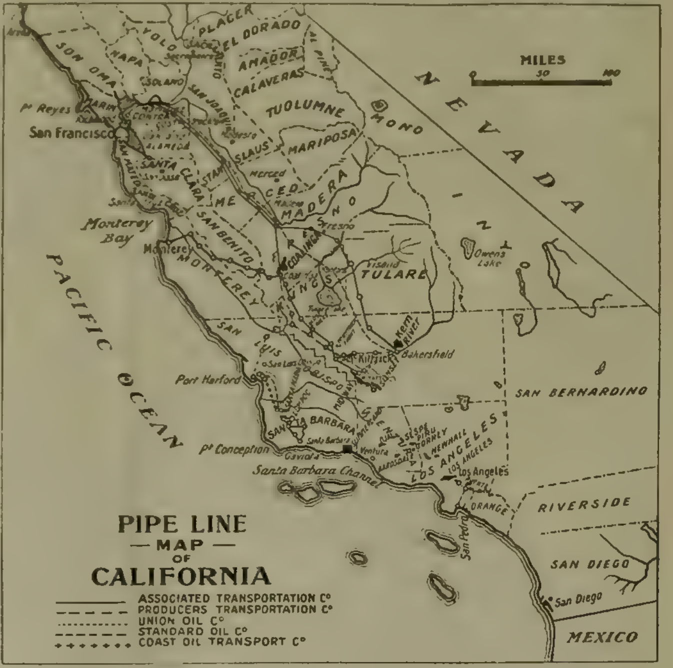
The values in the equation

$$D = r' + r'' + r'''$$

then vary from D = 16 to D = 25. In words: the investment in a partly developed oil property surrounded by producing properties, must be based on a capitalization of the estimated net profits, at rates varying from 16 to 25%. This investment consists of two parts; one covering the purchase of the property, and the other covering the money set aside as working capital for the proper development of the property. The revenue on the first must be covered by the net profits of the property at the time of the purchase, and must then represent these profits capitalized at rates varying from 13 to 15%, r′ + r″ + that portion of r‴ representing the risk of the fluctuation in the market value of the oil.

CLASS 2: *Properties surrounded by producing properties, but not developed.* In this case we have no net profits. A study of the conditions of the surrounding properties will give the engineer data on which to base an estimate of the probable capacity of the wells to be drilled. In this case profits will only begin to realize after a certain lapse of time; the risks due to possible fluctuations in the market value of the oil are greater than in the first class, and ought to be placed at the higher value, 5. The risks of loss of either capital or interest during development work are also somewhat larger, and may be estimated to vary between 5 and 10.

As the net profits will only be realized after a certain amount of development work has been done, we have in this case to consider deferred dividends. Let the term r⁗ represent the rate necessary to make up the loss of interest during the deferred period. For instance, assume it will take two years before the property can be placed on a dividend-paying basis, and assuming the life of the property at 15 years, then:



PIPE LINE
— MAP —
OF
CALIFORNIA

$$r'''' = r' + r'' + r''' \frac{15-13}{13}$$

At least a portion of the working capital will have to be expended before profits can be realized; the total capitalization will be estimated upon the basis of 23 to 28% for the estimated net profits after two years operation, and after deducting from this figure the working capital, we obtain the investment in the purchase of the property.

CLASS 3: *Properties with producing wells, but only partly surrounded by producing territory.* In this case the risk of loss of either capital or interest during development has to be placed higher than in the first class; I suggest the limits at from 5 to 12. For the other terms the values suggested for the first class can be used. A producing property only partly surrounded by producing properties must be based on a capitalization of the estimated net profits, at rates varying from 18 to 27%, and that part of the investment representing the purchase of the property must represent a capitalization of the net profits at rates varying from 13 to 15 per cent.

CLASS 4: *Properties partly surrounded by producing territory, and undeveloped.* In this case, as in that of the second class, the risks due to the fluctuations in the market value of the oil have to be placed at a higher rate than in the first class. Those of loss of either capital or interest during development are higher than in the third class, and I suggest placing the limits at from 6 to 14. The term providing for deferred payments, as explained in the second class, will also have to be introduced. The total capitalization will be estimated upon the basis of 24 to 33½% of the estimated net profits after two years operation, and the investment for the purchase of that property shal only represent that sum less the working capital.

CLASS 5: *Properties with producing wells, but at a short distance from other producing territory.* In this case the risks of loss of either capital or interest during development are much larger than in the former cases, and ought to be allowed figures varying from 8 to 16. Generally the number of wells in this case is small, and the production relatively small. The facilities for marketing the oil are also generally insufficient, so that the net profits at the moment of purchase cannot be given the value allowed to them in the first and third class; in other words, r''' will have to be increased, and r'''' will have to be allowed a certain value. The basis of capitalization will then be:

$r' = 5$

$r'' = 5$

$r''' =$ from 13 to 21.

r'''' on the basis of 1 year until dividends are paid $=$

$$(r' + r'' + r''')\frac{1}{14}$$

Consequently this varies from 24½ to 33% on the estimated net profits after one year's operation, while at least part of the working capital will have to be deducted to arrive at the investment allowed for the purchase of the property.

CLASS 6: *Properties at a short distance from producing territory, but undeveloped.* In this case the risks of loss of either capital or interest during development are larger than in the fifth class, and should certainly be allowed figures varying from 10 to 20. The deferred dividends ought to be figured for a period of 2½ years, and the basis of capitalization will then be varying from 30 to 42% of the estimated net profits after 2½ years of operation, from which amount the working capital has to be deducted to arrive at the investment allowed in the purchase price.

CLASS 7: *Properties with producing wells, but at a great distance from other producing territory.* This case is governed by the same considerations noted in the fifth class, except that the risks of loss of either capital or interest are larger and ought to be allowed figures varying from 12 to 20. The probable time before the property will be on a dividend-paying basis may be placed at two years, and the deferred dividends figured accordingly. The capitalization will then vary from 31 to 40½%, based on the estimated net profits after two years' operation, from which amount the working capital has to be deducted to arrive at the investment allowed for the purchase of the property. It may often be necessary to include in the working capital at least a part of the expenditure required to connect the property with a line of transportation of the oil.

CLASS 8: *Properties at a great distance from other producing territory and undeveloped.* In this case the property has no actual value, as J. R. Finlay remarked in his report to the Board of State Tax Commissioners of Michigan: "It is plain that where no deposits have been worked and none have been even proved to exist, the definite factors which can be applied to the valuation of an active property are lacking. In this case no definite appraisal can be made. A figure only represents a guess. I can see no way to come to any conclusion about such lands, other than to attempt such analysis of the facts as may limit the range between which guesses will be reasonable."[3]

In the foregoing I have tried to lay down some lines along which an approximate estimate of the valuation of oil lands can be made. I hope that other consulting engineers will criticize my work, and thereby help to clear up this question, which is, in my opinion, a very difficult problem for the consulting engineer when called upon to report as to the advisability of the purchase of an oil property.

Oil-Mixed Portland Cement Mortar and Concrete

By L. W. PAGE

*In October 1909 I made the discovery that oil in considerable quantities could be combined with wet portland cement paste by a simple mixing process. It was noted that when oil was added to wet cement it disappeared completely when mixed for a few moments, and, furthermore, that there was no apparent separation of the ingredients upon setting. Experiments were at once begun with various kinds of oil, to ascertain which was best adapted for the mixture. After these preliminary inquiries were completed, tests were conducted, or are now in progress, in order to investigate the properties of oil-mixed cement, mortar, and concrete. The materials used consisted of portland cement, river sand, and ¾-in. crusher-run gneiss. The oils selected for use were seven varieties of fluid residual oil, varying in viscosity from 2.5 to 65 and in specific gravity from 0.893 to 0.945, and one sample of cut-back oil asphalt. The cement complied with the specifications recommended by the special committee on Concrete and Reinforced Concrete. Of the sand 17% was retained on a No. 10 screen and 96% on a No. 80. Of the stone 28% passed a ¾-in. mesh screen. The sand contained 37% voids, the stone 43 per cent.

Time of Setting.—The addition of oil retards both the initial and final set. The effect of 10% of oil is to increase the time of initial set about 90%, and the time of final set about 60 per cent.

Crushing Strength.—Concrete, like mortar, when mixed with oil, shows a decrease in strength, that containing 10% of oil having roughly 75% of the strength of plain concrete when stored in water. Air-cured concrete, mixed in proportions of 1:3:6 and 1:3:5, containing 10% of oil, has 65 and 75%, respectively, of the strength of the plain concrete mixtures. At the completion of the one-year tests on compression, a marked increase in strength is shown over similar tests at six months. The next tests will be made at the expiration of two years.

Toughness.—Cylinders of concrete, 6 in. in diameter and 6 in. high, were tested in the Page impact machine under blows of a 10-kg. hammer, falling upon a 5-kg. plunger from successively increasing heights of 1 cm. The results of this test indicate that the toughness or resistance to impact of oil-mixed concrete differs but slightly from that of plain concrete.

Modulus of Elasticity.—Tests for the modulus of elasticity were made on specimens of the usual size, 8 in. in diameter and 16 in. high. The results indicated that the addition of oil to concrete has very little effect on its stiffness, the initial modulus of elasticity, with a few exceptions, showing but little change. The effect of storing in water is to increase the modulus of elasticity to more than that of air-cured specimens, and is as true with oil as without it.

Permanent Set.—In the endeavor to discover the effect of oil on the elasticity of concrete, micrometer readings of permanent set were taken after releasing the load to its initial value of 500 lb. In 1:3:5 concrete, containing as much as 10% of oil, the permanent deformation existing after the application of 500 lb. per square inch was less than that in the specimen containing no oil. This was true of both air-cured and water-cured specimens. The elasticity of 1:3:6 concrete appears to suffer with the addition of oil, the permanent set of the 10% oil mixture, air-cured, being 0.00076 in. per inch of length, as against 0.00019 in. for the plain concrete specimens. The corresponding ratio appears to exist for the water-cured specimens. The permanent set of the 10% oil mixture was 0.00017 in. after the application of 500 lb. per square inch. Here, again, the beneficial effect of storing in water is well marked, the permanent set being very small for water cured concrete, when compared with that cured in air.

---

*Abstract of a paper presented before the Amer. Soc. of Civil Eng., November 1.

Absorption. In order to determine the waterproofing qualities of oil mixed concrete, compared with those of a plain mixture, absorption tests were made on 1:3:6 concrete cylinders, 6 in. in diameter and 6 in. high. The cylinders were dried to constant weight in an oven, after being cured for 15 days in air. They were then completely immersed in water, and were weighed every day until they had attained constant weight. The addition of oil decreases greatly the percentage of absorption, the cylinder containing 10% of oil absorbing but 1.7% of water, based on the dry weight, while 6.25% was absorbed by the cylinder containing no oil. In almost every case the maximum absorption was attained within one day after immersion, and, furthermore, the rate of absorption seemed to be inversely dependent on the quantity of oil added. It will be noted that there is approximately only 0.5% difference between the absorption of the cylinders containing, respectively, 10 and 25% of oil. The inference to be drawn from this fact is that 10% of oil is nearly as effective as 25%, as far as waterproofing is concerned.

Four vessels of 1:3 mortar, each 2½ in. high, about ½ in. thick, and having an outside diameter of 8 in., after hardening in moist air for one week, were immersed in water to a depth of 5 cm. Vessel No. 1 was made with no admixture of oil. A damp spot appeared inside about 1 min. after immersion. In one hour it was completely water-soaked, the moisture having climbed by capillarity above the level of the surrounding water. Within a few days after immersion, water had penetrated the plain mortar vessel until its level inside was the same as that outside. Vessels No. 2, 3, and 4 contained, respectively, 5, 10, and 20% of oil. After an immersion of six months, the interiors of the oil-mixed vessels are as dry as they were on the day they were placed in the water. A corresponding series of tests was made on mortar vessels, made to contain water, with like results. The plain mortar vessels leaked, and those of oil-mixed mortar were perfectly tight. These results show with certainty the waterproofing qualities of oil-mixed mortar and concrete.

Permeability.—The following tests were made on specimens of 1:3 mortar, 3 in. thick and 6 in. in diameter: Plain 1:3 mortar, at the age of 28 days, under a pressure of 30 lb. showed dampness in about ½ hr. Under a pressure of 40 lb., applied for 24 hr., the leakage amounted to 146 c.c. Specimens of the same mixture, but containing 5 and 10% of oil No. 4923, remained perfectly dry for 24 hr., under a pressure of 40 lb. A ½-in. coat of 1:3 mortar, containing 10% of oil No. 4923, applied to the surface of a very porous concrete, was absolutely effective in preventing all leakage, even under comparatively high pressure.

Bond Tests.—Tests were made to determine the relative strength in bond of oil-mixed and plain concrete. Specimens were made of 1:2:4 concrete, mixed with 23.5% of water, based on the weight of cement and dry sand, making a rather wet mix. Rods 12 in. long were embedded in the centre of cylinders 8 in. in diameter and 8 in. long, one end projecting about ½ in. through the bottom. The specimens were bedded in plaster of paris on a cast-iron plate mounted on a spherical bearing block. The test consisted in pushing the rods through the concrete, the point of failure being taken at the drop of the scale beam. Two kinds of bars were used, plain and deformed. All specimens were tested at 28 days. The results show that the effect of oil is to decrease the bond strength, the decrease depending on the quantity of oil added. It is evident that the bond between plain bars and concrete is affected so seriously by the admixture of oil that it would be extremely inadvisable to use such a combination. The bond of deformed bars is not affected so seriously. With an admixture of 10% of oil, which is as much as is necessary to use, the bond strength is 84% of that attained by the mixture containing no oil.

Service Tests.—During April and May, 1910, two bridge surfaces of oil-concrete were laid at Ridgewood, N. J. In the Borough of Richmond, New York City, during May and June, 1910, about 400 ft. of street surface was laid with different aggregates. About 300 ft. of street in Washington, D. C., was surfaced in June 1910. Numerous inspections of this work have been made, and, up to the present time, it is all in very good condition. About ½ mile of roadway, laid with 10% oil-concrete in the suburbs of Harrisburg, Pa., in the summer of 1910, is also reported to be in very good condition. A vault, 112 ft. long and 18 ft. wide, in the United States Treasury Department, was built in the autumn of 1910. The side-walls of this vault contain 10% of oil. Its roof was constructed of ordinary reinforced concrete with about 3 in. of 10% oil-concrete on top. For several months this roof was subjected to a head of water of several feet without showing any signs of leakage. Another vault, in the north end of the Treasury, on account of leakage, has never been available for storing anything of value. Its roof was treated with oil-concrete, and is now perfectly dry. Numerous floors in the sub-basement of the Treasury Department, and a floor in the Office of Public Roads, have been constructed with 10% oil-concrete, and have remained absolutely free from dampness. A tank, about 12 ft. long, 4 ft. wide, and 4½ ft. high, constructed in the Office of Public Roads during the winter of 1910, has been continually full of water, and has not shown the slightest signs of leakage.

Summary of Conclusions.—The following tentative conclusions as to the effect of the oils used in cement and concrete may be drawn from the foregoing investigations:

1. The tensile strength of 1:3 oil-mixed mortar differs very little from that of plain mortar, and shows a substantial gain in strength at 28 days and 6 months over that at 7 days.

2. The times of initial and final set are delayed by the addition of oil, 10% of oil increasing the time of initial set by 90%, and the time of final set by 60 per cent.

3. The crushing strength of mortar and concrete is decreased by the addition of oil to the mix, concrete with 10% of oil having roughly 75% of the strength of plain concrete at 28 days. At the age of one year the crushing strength of 1:3 mortar suffers but little with the addition of oil in quantities up to 10 per cent.

4. The toughness of resistance to impact is affected but slightly by the addition of oil in quantities up to about 10 per cent.

5. The stiffness of oil-mixed concrete appears to differ but little from that of plain concrete.

6. The results of tests for permanent deformation do not indicate that a law is followed by oil-mixed concrete.

7. Oil-mixed mortar and concrete containing 10% of oil have very little absorption, and, under low pressures, both are waterproof.

8. Oil-mixed mortar containing 10% of oil is absolutely water-tight under pressures as high as 40 lb. per square inch. Tests indicate that oil-mixed mortar is effective as a waterproofing agent when plastered or painted on either side of porous concrete.

9. Bond tests show the inadvisability of using plain bar reinforcement with oil-concrete mixtures. With deformed bars the bond is not weakened seriously by the addition of oil in quantities up to 10 per cent.

A patent has already been granted to me for mixing oil with portland cement concrete and hydraulic cements giving an alkaline reaction. All citizens of the United States are at liberty to use this process without the payment of royalties.

The latest practice of some of the best mining companies involves the use of steel timbering in place of the wooden elements formerly used, and the development of reinforced concrete as a building material for the structures underground. Stables, for example, are made of reinforced concrete, and are not only more sanitary, more easily kept clean and sweet, but are practically noncombustible, and a fire, once started, can be closely localized.

Workmen's Liability Insurance

By C. O. Bartlett

*During the last few years, and especially last year, much has been said about workmen's liability insurance, and a number of States have enacted laws bearing on this important question. The bone of contention is, who shall pay the bill? It is certainly nice for every workman in a mine, factory, or on a farm to have a workmen's insurance policy, especially if some one else pays the premium.

There seems to be a general impression that insurance companies are robbers, that they have made vast fortunes out of the employees' insurance business, and if the State or general government would go into this business, the rate would be very much less. Now the fact is, judging from the past, that all business done by a city, State, or general government costs nearly twice as much as when done by private corporations or individuals, and there seems no reason why there should be any variation from this general rule in the insurance business. I think it is fair to assume that when any State, or the United States as a whole, engages in the liability insurance business, the cost will increase as in other lines, and the idea that a lot of money may thus be saved is only a myth.

In taking up this question, it should be considered most carefully that where there is one large mining corporation, or other corporation, there are hundreds of smaller ones doing business in every State, and I wish to speak especially of these medium-sized corporations or companies. The large companies, like the Philadelphia & Reading Coal & Iron Co., the United States Steel Corporation, the Pittsburg Coal Co., the Standard Oil Co., the International Harvester Co., and some others of similar type, control very largely the selling prices of their products; in other words, when they say 'Thumbs up!' up they go, and when they say, 'Thumbs down!' down they go. But the medium fellow, with competition on every corner, cannot do this, and if we add to the expense of these companies, even at the rate of 1% a year on the capital stock, it will mean that thousands will go to the wall.

Take the case of the State of Ohio, which is one of the largest manufacturing States in the Union, one of the best situated for manufacturing purposes, with plenty of coal at a low price and of a good quality, with cheap iron ore of a good quality, the best of water and rail transportation facilities, the best of farming lands from one end to the other to supply bread and meat, altogether, perhaps, more advantages than any other State in the Union. Two years ago a tax of one-tenth of 1%—that is, a special tax of one-tenth of 1%—was put on all corporations, and last year this was increased by 50%, making a yearly tax of 1½ mills on every dollar of the capital stock. In other words, a company of $60,000 capital stock is now compelled to put in the State treasury as a special yearly tax $90. This may seem like a small amount, but last spring more than 1200 of the Ohio corporations were delinquent in this special tax, the delinquency amounting to more than $2000.

To further illustrate, if a tax of 1c. per ton were put upon all coal mined in the United States, it would mean nearly 1% on the selling price of all the coal mined in the United States; according to E. W. Parker, the output of coal in the United States in 1910 was 501,000,000 tons, and at 1c. per ton means over $5,000,000. I do not hesitate to state that the 33 million tons of coal mined in the State of Ohio last year did not pay dividends to the owners of the mines of more than 2%, and a tax of 1% would mean ruin to many of them, for I assure you that a great many mines in Ohio are paying only small dividends.

According to this same report by Mr. Parker, the average price of bituminous coal is a little over $1 per ton. It has never been estimated by any actuary that the workmen's liability insurance tax against a mining or other company would be less than this amount, and probably it would be very much more, possibly 200% more; in fact, insurance companies state that it will be fully as much, and there is no reason to believe that the insurance companies are untruthful. At any event, so important a measure as this should receive the most careful consideration. Looked at carefully, and boiled down, it simply means that all workmen in mines and factories will have a liability insurance policy, so that in case of accident they shall draw a certain amount per week, say 60% of the amount of their wages; that in case of death their families will draw a certain amount per week, up to a certain maximum, say $3000 or $4000.

So far this seems easy. It is certainly a good thing for each workman to have insurance against injury or death, but the question then arises, who shall pay the bill? Naturally the workmen are anxious for the employer to pay the premium and the employer is naturally loath to do it. The fact that over 80% of the men engaged in business, mining or other kinds of business, do not meet with success should not be forgotten. Again, I wish to say, to miners and manufacturers, that if it is legal to insure the workmen in the mines and factories throughout the cities and towns, it is equally as important to the workmen on the farm.

That all manufacturers are much interested in this question and are anxious to have some law enacted, there is no question, and I feel I am voicing the sentiments of a large number of the manufacturers in Ohio when I state that they do not feel that they should pay the premium. It seems to me that the only right way to do this is for the employer to pay half and the employee pay the other half, and let the government, either State or National, bear the expense of the burden of carrying out the provision of the law. The true object of liability insurance should be to prevent accidents, and from an experience of many years, I feel absolutely confident in making the assertion that if any mine or factory insures its employees and pays for the entire insurance, the number of accidents will increase rapidly. But if you say to the workman, you may pay half of this and I will pay the other half, then you will have prevented to a very large degree all accidents, for the reason that the workman will be equally as interested and will try in every way to prevent accidents as well as the employer.

Another important point, and by far one of the most important of this whole question, is that this will bring the employer and employee into a close and friendly relationship. This is one of the great questions which the manufacturers are trying to solve today for, say what you will, all are in the same boat and should work in harmony as much as possible. It is a terrible thing for the head of a mine or factory to learn that one of his workmen has met with a serious accident, and it is certain that manufacturers are only too glad to do anything in their power to prevent these things. But accidents will happen, and the effort is to prevent them, so far as possible. In other words, I wish to emphasize the fact that prevention should be the main object in any workmen's liability insurance law. That should be the goal at all times, in all places, and under all conditions.

Much has been said about the splendid laws regarding liability insurance in European countries, and especially is this true of Germany; according to the addresses and articles in the magazines it is almost a paradise to work in Germany. But, like all other questions, there are two sides to this one, and of the other side not so much is heard. They do not tell us that the taxes in Germany are two to four times as much as they are here. It might be expected that many workmen would immediately go back to work under these favorable conditions, but how many mechanics from your town left for Germany last year? I venture to say that you would count the number on your four fingers, and I can furthermore venture to say that when you can divide it by four in many cases you can subtract one from this amount. On the other hand, how many of the workmen from that country have come

---

*Abstract of a paper presented at the American Mining Congress, October 1911.

to this country to better their condition? Over 180,000 German people came to America last year. In Germany the employers pay only one-third of the cost, and I repeat that it must be considered most carefully before our mining operators and manufacturers are burdened with the tremendous cost of workmen's insurance. If agitation and legislation against the business industries of America keeps on at the rate of the last two years, serious consequences will surely ensue.

Where the Horse-Whim Fails

By Dennis H. Stovall.

Our mutual friend, the mine foreman, will tell you that the horse-whim is good enough for a 'jack ass property.' By which we are to infer that beyond mines of this class the horse-whim has its limitations. After knocking round through Western mining camps, and visiting all sorts of mines, I am willing to state that it is an easy matter to estimate the management of a property when you see its hoist. This prominent feature of the mine's equipment does not always indicate the worth of the deposit, but it is a certain indication of what results are being obtained. Go into almost any mining district, and you will find one or more good properties abandoned, the camp deserted, the mill turning to rust and decay, simply because the management 'made a mistake.' You soon discover the mine is filled to the collar with water, flooded beyond hope. The 'mistake' was in placing an inadequate hoist and pumping plant. A good hoist, operating a skip, either by single or double-compartment shaft, will keep the wettest mine dry, should the pumps fail.

GASOLINE HOIST FOR A SMALL PROPERTY.

The horse-whim is not altogether to be despised. There are times and places when it plays a most important part. Equipment of this sort costs but little, and does excellent work in prospecting when only a few men are employed. But in this day of cheap gas-engine power, the horse-whim is becoming more and more a useless adjunct. As a general rule, the intelligent mine manager can make a close estimate on the real worth and stability of his property when a depth of 200 ft. is attained. Then is the time to place an adequate hoist. Enlarging this feature of the equipment every time a deeper level is tapped will prove an expensive business, therefore it is better to place a large hoist at once, or install one of the unit type, which can be enlarged with each stage of development, without the removal or replacement of the original parts.

At an Oregon property that was originally equipped with a horse-whim, hoisting by this method cost 25c. per ton. Then a small steam plant was installed, and hoisting was reduced to 15c. per ton. Finally this proved inadequate, and a double-drum hoist of the latest type was erected. With this equipment the expense of lifting the ore from the mine dropped to 5 or 6c. per ton. Had this plant been placed at the time the horse-whim was thrown aside, much unnecessary expense would have been saved. A plant of this type costs between $5000 and $8000, depending upon the situation of the property, but it will serve the mine for all time. With a 150-hp. engine, and with a lifting speed of 500 ft. per minute, operating double-decked cages, it not only removes all the ore as fast as the men break it down, but takes care of all up-and-down transportation, such as the moving of stulls, tools, powder, and men.

Where the ore is low grade, every item of expense must be cut down to the lowest possible minimum. If the property is opened by vertical or inclined shaft, hoisting and pumping are two items that must be carefully calculated. Failure in this has proved to be the principal reason why a number of properties never reached the producing stage. To again quote our mutual friend the boss, "pumpin' and hoistin' are just like interest on a mortgage—grinds away day and night."

HORSE-WHIM FOR PROSPECTING WORK.

Barytes, or barium sulphate, is a heavy crystalline mineral, white when pure, which is very little affected by acids, alkalies, or corrosive gases. In 1910, according to E. F. Burchard, of the United States Geological Survey, the United States produced 42,975 short tons, valued at $121,746, a considerable decrease as compared with the figures for 1909. Barytes is an interesting and useful product. By far the greater part of the mineral produced, says Mr. Burchard, is consumed in the manufacture of mixed paints. It is not satisfactory as a pigment if used alone in oil, for its crystalline nature renders it too transparent to give good hiding power, and to be of any advantage it must be used in only moderate percentages in mixed paints, which consist principally of the lead and zinc-white pigment. Its use as an adulterant in white lead or in any other pigment or commodity is not legitimate and should be discouraged by the producers. There are sufficient legitimate uses for this valuable mineral to create a healthy market for it if properly handled. Barytes is used also in the manufacture of lithopone, a very white pigment that is suited most particularly to interior use and is employed in enamels and wall finishes. Barium salts are reported to be used in brickmaking in order to overcome the efflorescence of bricks. Other uses for barytes are in the manufacture of rubber, wall paper, asbestos cement, and poker chips, and in tanning leather.

The Past, Present, and Future of Copper

By Horace J. Stevens

[*]The great copper industry of the present day is a thing of small beginnings. In 1811, the world's production of copper was a trifle under 10,000 long tons, an amount smaller than was secured last year by any one of more than twenty different mines. During the present year the Anaconda mine at Butte has produced, during nearly every month, as much copper as was supplied by all the mines of the world in the entire year of 1811.

Fifty years ago, in 1861, the world's output of copper was but a trifle more than 100,000,000 lb., a production exceeded, in 1910, by the Anaconda Copper Co., American Smelters Securities Co., and Phelps, Dodge & Co. The production of the year 1900, the last of the nineteenth century, was just fifty times as great as that of the year 1800. Should the same ratio of increase be maintained during the twentieth century, the output of the year 2000 would be 24,318,150 long tons of copper, twenty-five times as much as the present production, and even a fifty-fold increase for the twentieth century would allow an average increase of less than 4%, while the average annual increase, for the decade beginning 1900 and ending 1910, was almost exactly 7%, compounded yearly. Those who foresee a complete collapse in the copper industry would do well to give consideration to the actual figures of increase during the past. The copper industry does not move forward at even an approximately steady rate, from year to year, but is given to advancing by great leaps, almost inevitably followed by periods of quiescence, or even of actual retrogression. High prices for the metal stimulate production, while curtailing consumption, and, as a direct consequence, output is increased, which decreases prices, which in turn brings about decreased production, due to the inability of small and weak producers to stand the strain of low prices. Decreased production again brings about high prices, and the cycle is begun anew. Much the same conditions existed in the American iron and steel industry for fifty years, until the formation of the United States Steel Corporation, which, while unable to prevent periods of depression, as its sponsors fondly hoped, has proved a wonderfully steadying factor in the iron and steel market, serving the purpose of a gigantic balance-wheel.

The growth of the copper industry is best shown by the following figures of the world's production, by decades, in long tons: 91,000 tons in the decade ending 1810; 96,000 tons in 1820; 135,000 tons in 1830; 218,000 tons in 1840; 291,000 tons in 1850; 507,000 tons in 1860; 900,000 tons in 1870; 1,189,000 tons in 1880; 2,373,000 tons in 1890; 3,708,000 tons in 1900; 7,390,000 tons in 1910. The influence of the electrical industry upon the consumption of copper is plainly shown by the figures since 1880. The production of the seventh decade of the nineteenth century was only 900,000 long tons, or a trifle less than ten times the output of the first decade of the century, while the production of the last decade of the century, ending 1900, was more than forty times the output of the first decade, and was more than four times as great as that of the decade ending in 1870, only thirty years before. The output of the decade ending 1910 was more than six times as great as the output of the decade ending in 1880, and was almost exactly double the production of the previous decade ending in 1900. The production of copper by the world, amounting to approximately 7,390,000 long tons, for the decade ending 1910, amounted to more than three-fourths of the total world's production of copper for the entire preceding century.

Figures of production and consumption of any given commodity in universal use may differ from year to year, according to whether a surplus is accumulated, or a preceding surplus is drawn upon, but over long-term periods production and consumption necessarily are the same, and, figured by decades, it is safe to say that the figures of production are practically the figures of consumption. At present there is a copper surplus, of which much is heard, but to show how comparatively unimportant the present surplus is, when compared with the figures of output for the preceding decade, it may be stated that the world's surplus of copper, at the present time, is slightly less than 300,000,000 lb. of finished metal, or a trifle under 135,000 long tons, an amount less than 5.5% of the total production of the decade, and equivalent to only about eight weeks supply of copper at the present time, measuring the supply either by productive capacity or by consumptive demand.

Exact figures are available regarding production, dividends, costs, and metal prices of the mines of the Lake Superior district since the first production was secured, in the year 1845, the total ouput for that year having been only 24,880 lb. of finished copper. The total production of fine copper, by Lake Superior mines, from 1845 to 1910, inclusive, a period of sixty-six years, or two-thirds of a century, was 5,122,478,402 lb., having a gross value of $726,849,840, from which were paid dividends of $182,824,770, the ratio of dividends to gross values, for this entire period, amounting to 25.1%, and dividends, divided by copper production, show average dividend payments of 3.56c. per pound. The average price received for all Lake Superior copper, for this period of sixty-six years, was 14.19c. per pound, which, after deduction of dividends, leaves an estimated cost of 10.63c. per pound, for all years. By adding the figures of expenditures on unproductive mines, amounting to about $60,000,000, the cost of Lake Superior copper would be made almost 11½c. per pound, and by adding a further $15,000,000 for assessments on mines that have since repaid in dividends the original assessments, the cost of copper would be made about 11.85c. per pound, leaving a net margin of profit, for the entire production, of almost exactly 2c. per pound, plus the present aggregate value of the various active mines.

Omitting the production of mines that have not proved profitable, the average cost of Lake Superior copper yielded by dividend-paying mines, has averaged about 9.5c. per pound, for all years, and the present cost of making copper, by all of the producing Lake Superior mines, probably is slightly above 9c. per pound. The actual average cost of making copper, in the leading producing fields, probably is between 9 and 10c. per pound, at the present time. Some of the newer fields, which are skimming their cream, show lower costs, but it is difficult to see where the world will be able to produce its copper, in years to come, at an average cost materially under 10c. per pound, this figure excluding the limited production of badly planned and badly managed mines, which yield only a small fraction of the total copper output, but secure their metal at an average cost very much higher than the average cost of all mines.

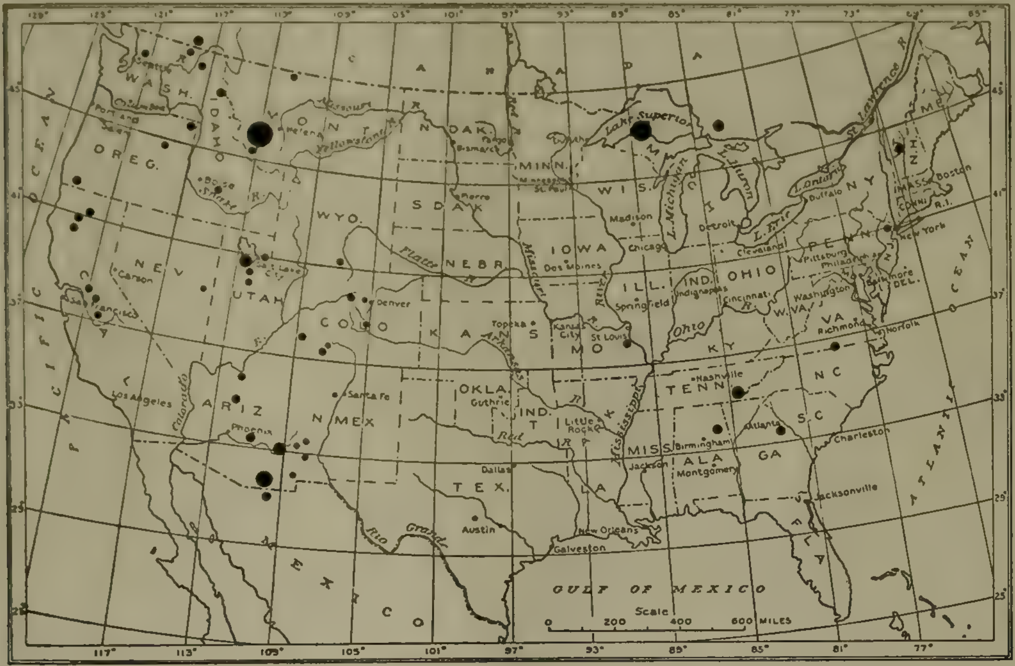
For the immediate future, the supply of copper in sight is fully adequate, and no unduly high prices need be anticipated, but the figures clearly foreshadow another boom period, within the next two to four years, at which time the alarmists will be as badly scared, for fear that the copper supply is petering out, as they now are for fear that the production is so much greater than consumption that nothing but permanent disaster is in sight. Allowing an average increase of consumption of 7% yearly, the figure that has ruled during the first nine years of the present century, the world's requirements of copper will amount to approximately 1,650,000 long tons in 1920; 2,975,000 long tons in 1930, and 5,350,000 long tons in 1940—the last named year, now only 29 years ahead, calling for a copper output almost six times that of the present rate. Twenty-nine years ago, or in the year 1882, the world's production of copper was 181,622 tons, or about one-fifth of the present output. Allowing for even a five-fold expansion during the next three decades, to correspond with the five-fold expansion in the three decades past, the world's copper requirements in 1940 will be more than 4,500,000 long tons. Should the ratio of increased production and consumption remain at an average of 7%, for the balance of this century, the world would yield and consume, in the year A. D. 2000, about 175,000,000 long tons of copper, a quantity of the red metal more than double the tonnage of the world's present production of iron and steel.

---

[*] Abstract of a paper presented before the American Mining Congress, October 1911.

A survey of the progress made by the copper industry during the first decade of the twentieth century, now lacking only a few weeks of completion, shows no revolutionary changes, but does show steady and in some cases phenomenal progress, in nearly every division of the industry. In the matter of mines, the old districts of Butte and Lake Superior remain the largest producers, but Arizona, with a half dozen important copper fields, passed Montana in output in 1908, though again taking second place in 1909. In copper mining, the most important development of the decade has been the making of the so-called porphyry mines, in which disseminated copper sulphides are mined from schistose or porphyritic country rocks. The development of such important new producers as the Utah Copper, Nevada Consolidated, Miami, and others of this class, has alarmed many people, who jump to the conclusion that the so-called porphyry mines must close down the older mines, developed on veins in Butte and other areas, and on the stratified trap beds of Lake Superior. There is no real occasion for this alarm, as the porphyry mines, while highly important, are not apt to be developed in large numbers. In fact, the entire western part of the United States has been scoured, by the keenest and strongest aggregations of capital in the copper business, for promising deposits, with a net result insignificant in the number of properties developed, though highly important in output already secured, and even more important in promise of future production. When the Mesabi iron range was opened, eighteen years ago, a similar wave of pessimism swept over the mine-owners of the older iron ranges in Michigan and Wisconsin, but time has proved that the high-grade ores of the Mesabi, capable of being mined by steam-shovel, at wonderfully low costs, are absolutely necessary in furnishing an adequate supply of ore to the iron and steel works of this country, and similarly it will be found, as time passes, that the production of the porphyry mines is absolutely essential in supplying the copper needed by the world, at anything like a fair figure to the consumer. Processes of actual ore extraction have been modified and improved, in many fields, with a resultant increase in safety to miners, and decrease in cost of ore extraction. The steam-shovel has come to stay, in copper mining.

Strange to say, the copper mines, which are vitally interested in extending the use of copper, were somewhat slow in adopting electric power, but rapid progress has been made in this direction during the past decade, and all of the mines of Butte are now electrified, while there has been a great increase in the use of electric energy in the Lake Superior district. The constantly increasing use of hydro-electric power is now restrained, and further restraints are threatened, by the conservationists. The newly adopted system at the Anaconda mine, at Butte, which combines the utilization of hydraulic, electric, and pneumatic power, offers great possibilities of pliancy and economy, and the lead of the Anaconda is likely to be followed by many other important mines.



MAP OF COPPER REGION OF THE UNITED STATES.

Perhaps the most striking progress made during the past decade, in any division of the copper industry, has been in smelting. No new principles have been adopted in either reverberatory or blast-furnace work, but reverberatories of a gigantic size hitherto unknown have been adopted at many plants, while even more striking progress has been made in the capacity of blast-furnaces. Ten years ago a 300-ton blast-furnace was considered exceptionally large, and near the possible maximum of size, but the Washoe works of the Anaconda Copper Mining Co., again blazing the way, now has two furnaces, each 56 in. by 51 ft. in size, with a maximum daily smelting capacity of 1800 tons each, and a third furnace that is 56 in. wide and 87 ft. long at the tuyeres, this mammoth furnace actually having smelted 3100 tons within 24 hours. It has been my privilege to see this great blast-furnace with smelting in progress at the western end, while the eastern end was frozen, and repairs in progress within the bosh.

The past decade has seen a further extension of the electrolytic process of refining, and the great bulk of the world's copper now is refined by electrolysis. In fact, very little finished copper, other than electrolytic, reaches the market, except from the Lake Superior mines, the product of which commands a premium by reason of its extra toughness and superior adaptability to drawing and stamping. With depth, many of the Lake Superior mines have shown a marked increase in arsenic, and for this reason a considerable part of the Lake Superior copper now is refined electrolytically, and sold as electrolytic and not as Lake copper. [Further data regarding the refining of copper will be found on another page in this issue.]

The price of 26¼c. per pound, reached in March 1907 by Lake copper, was not the result of any corner, but came about through an ill-advised scramble by consumers, who feared that they could not secure the metal. As a result of the high price, consumption was curtailed sharply in all directions, as happens inevitably under such unsatisfactory price conditions, and the copper industry of the world still suffers from the existence of a surplus of slightly under 300,000,000 lb. of metal, remaining from a surplus that, including both visible and invisible supplies, reached about 450,000,000 lb. at the end of 1909, since which time there has been a small but steady decrease in surplus, from month to month. [Statistics of production and marketing of copper throughout the world were given in full in the *Mining and Scientific Press* of October 28.]

The leading copper producers of the world are now operating under check, a 10% reduction in output having been put into effect in August of last year. Under the Sherman Anti-Trust law, this checking of production would be considered criminal, if it could be proven, yet the reduction of output was absolutely necessary in order to save the copper industry from a prolonged period of utter demoralization, during which scores of millions of dollars would have been lost by investors, and a quarter million or more working men would have suffered severely, many of them losing their jobs, and the remainder suffering severe cuts in wages. We have the authority of eminent statesmen, totally devoid of business experience, that the Sherman act is a panacea for all ills of the body politic, yet no sensible business man would do otherwise, if he had the power, than to reduce production at a time when a surplus product threatened not only the small remaining profits, but the very foundations of the copper industry. The issue thus is drawn very plainly between our present politico-criminal law and all the laws of business and political economy.

The tendency in copper mining, as in all other branches of industry, is toward combination in ever-larger units. This tendency is based upon and governed by purely economic laws, and the laws of political economy are so much stronger than any law ever devised by a parliament, or any ukase ever promulgated by a despot, that it requires no spirit of prophecy to forecast the ultimate outcome of the present clash between the laws of political economy and the laws of congress.

The Guggenheims are the bogey-men with which the public are most frequently alarmed. We have had it dinned into our ears, by innumerable patriots seeking office, and repeatedly set before our eyes, in every yellow newspaper and muckraking magazine, that "the Guggenheims are stealing Alaska." As a matter of fact, the Guggenheims control a copper mine in the interior of Alaska, that is a wonder in its way, yet which cannot be rated at more than a third-class property. This mine, the Bonanza, is a sort of copper-plated gold-brick, in that an interior core of limestone is surrounded by phenomenally high-grade bornite and copper glance. No competent mining man who has visited this property ever has estimated the amount of ore developed, and safely inferred, as capable of yielding more than 100,000,000 lb. of finished copper; a total production equivalent to only one year's maximum output by any one of the six leading copper mines of the world. In order to get this ore out of a wilderness, the Guggenheim interests have built the Copper River & Northwestern railway, a line of 195 miles length, variously estimated to have cost from $13,000,000 to $25,000,000. The gross value of all the copper contained in the Bonanza mine, taking the outside estimate of tonnage, is considerably less than the lowest estimate of cost of this railway, and the net profits derivable from the Bonanza mine, cannot, by the most liberal figuring, be estimated at more than $4,000,000 to $5,000,000. Instead of being commended for their enterprise and courage in building this railway through an arctic wilderness, the Guggenheims are held up to public scorn as thieves and robbers. This railway cuts through workable beds of coal, but is prohibited, by the Federal authorities, from developing or using this coal, and is compelled to import inferior coal, from British Columbia, at a cost more than double that of domestic coal, if its mining were permitted. Not only does the railway suffer from this arbitrary action by the Federal Government, but the 50,000 unfortunate American citizens who live in Alaska are compelled to pay double or triple the price they should pay for fuel, through the efforts to "save" the coal for some future use, at an indefinite date.

Purifying Water by Coagulation

The practice of using certain salts for the purpose of accelerating water clarification is of great antiquity. It originated in China, in all probability, thousands of years ago. It was used in Egypt for many centuries prior to its use in numerous plantations in the southern portion of the United States as an aid to the clarification of highly colored or very muddy waters. Coagulants have not had an extensive use in western Europe owing to the comparative absence there of muddy or highly-colored waters, but are now being used in quite a number of slow sand filtration plants in Belgium, Holland, and northern Germany.

The use of coagulants was not looked upon with favor ten or fifteen years ago, either in this country or in Europe. Careful scientific investigation into their use at a dozen places during the past fifteen years or more, particularly at Louisville, Pittsburg, Cincinnati, and New Orleans, and a complete absence of ill effects upon the health of the communities using regularly water treated in this manner have eliminated this feature. Coagulating processes are now recognized as not only necessary for the treatment of certain classes of waters, but as permissible for use with perfect safety.

The process has been carefully studied by the Royal Prussian Testing Station, and its merits are now recognized throughout the civilized world. The use of coagulants in connection with the preparatory treatment of water prior to its application to slow sand filters of the Pittsburg type is successfully practised in this country at Springfield, Massachusetts, Ferncliff and Poughkeepsie, New York; Indianapolis, Indiana, and is proposed for use in a number of larger cities. At Washington, D. C., for instance, provisions are being made to apply a coagulating chemical to the unfiltered water during muddy-water periods. Coagulants are also used in the preparatory treatment of water going to slow sand filters at Tokyo, Japan, Calcutta, India, and elsewhere. In connection with mechanical filter plants coagulants are always used, and it is safe to say that there are over 400 such plants in actual operation. A careful study of the practices of water purification in this country develops the fact that fully 12% of the urban population of the United States are being supplied with water purified by some process in which coagulation plays an important part.

At Cincinnati and New Orleans careful investigation with a view to ascertaining the advisability of using coagulants in connection with the clarification of water passed through quite large settling basins before application to filters of the Pittsburg type have shown the process to be entirely feasible, although somewhat expensive. It was found necessary to have a settling capacity following the application of the coagulating chemical equal to about 24 hours, otherwise some of the gelatinous precipitate would remain in the water as it entered the sand filter and would clog the layer immediately at the surface so frequently as to make the cleaning abnormally expensive.—*Engineering Record.*

Many salts have the property of causing the coagulation of the colloid silicates and hydrates which exist in dilute solutions such as river water. Lime and sulphate of soda are the cheapest and most convenient of these.

Along Mexican Trails

By Alexander J. Fraser

The completion of the Southern Pacific railroad along the Mexican west coast, with its branch to Alamos, and the building of the coast end of the Kansas City, Mexico & Orient railroad to El Fuerte in Sinaloa, marked the passing of the old order in muleback transportation and the closing of the coast trails of Sonora and Sinaloa. The completion of the latter road will completely eliminate the mule as a factor in freighting, and put an end to a picturesque phase of Mexican life along many historic trails of the interior. The advantages of the several railway towns as outfitting points for southwestern Chihuahua, the Sonora country adjacent to it, and northern Sinaloa, and the trails leading thereto, was the subject of discussion by some mining men while enjoying the refreshing evening breeze in front of the Hotel Central, at El Fuerte, after an uncomfortably warm December day.

El Fuerte is the headquarters for a large mining area, embracing such districts as the Lluvia de Oro, Calabacillas, Morelos, and others of less importance. From these districts, and from the haciendas—with their peon population—a large trade is derived. The little town lies along the east bank of the river, which, at this point, it is presumed, takes its name from the town. Seventy miles up stream the river is known as the San Miguel; still farther north and to the east, where its course is wildest and most crooked, the Indians baptized it Uruachi; while, near its source, in the wild country of the Sierra Madres, it passes under the name of Verde. This confusion of tongues and names may act as a stimulant to its, at times, excessive turbulence and irritability.

The town has its road, the Kansas City, Mexico & Orient railway, and wagon-trails, one of which, a broad thoroughfare, now partly covered with grass and weeds, deserves mention. Its beginning in Mexico is at the northern frontier, and its southerly route passes through Hermosillo, Alamos, Culiacan, and so on to Mexico City. In the days of the early settlers this trail witnessed scenes most picturesque and interesting. Two hundred years before the first panning of gold was done on Sutter creek, California, an endless succession of mule trains passed over this highway, each train with its conductor in the saddle and his crew *a pie*—a shouting, perspiring lot af sandalled brown humanity. Wares from the then distant lands across seas, brought over in barks and brigantines, and full rigged ships; silks from India and Japan; champagnes from France and Switzerland; fabrics from the looms of England and Persia; silver bullion southward bound, mingled with common products of the land on their final journey inland. The campfires on the hills at night; the laughing, singing *arieros;* the mules and burros, feeding, fighting, and neighing, are part of the memories of a great highway whose glory has gone forever. In those days such names as the Promontorio, Zambonia, Millionaria, Zapote, and others were famous, not only throughout Mexico but across the seas. Two centuries before the quartz lodes of Colorado were first discovered.

The Stilwell or Orient road, as the Kansas City, Mexico & Orient railway is called locally, makes a daily run from Topolobampo, its coast terminal, to El Fuerte, connecting at San Blas with the Southern Pacific system. Splendid things are promised for this road in the way of passenger comfort, when the gap between Choix and Sanchez is closed. A dozen cabs may be found backed against the station platform on the arrival of the train at noon, ready to absorb the passengers who wish to drive to town, six miles away. Seen from the mesa, as the cabs approach it, the town is rather attractive in appearance. The long low buildings, tinted pink and blue, with the tall cathedral spire in the centre, suggests some Oriental town. This pleasant impression is somewhat dispelled on entering the pueblo, by the usual monotony of Mexican architecture. The houses, mostly one storied, of adobe or brick, are typically Spanish. Their architectural evolution has been the same as that of houses in a majority of small towns in the country, over two centuries ago Spanish pioneers piled the adobe walls of their enclosure, four square, thick, and strong to withstand attack. It was then an Indian country, wild and unexplored. The sides and ends of the dwellings formed part of the walls in which narrow holes were cut to serve as windows and incidentally as port-holes. In some of the larger enclosures, large circular towers (*torreones*) were built at each end, in which the families lived when the haciendas were attacked.

Two hundred years later their descendants are found designing the brick or adobe walls of their squares and dwellings much on the same lines as their ancestors of frontier times. The bare enclosures of early days have given way to beautiful courtyards in the centre of the squares; yet the Spanish idea is still dominant in the low, flat-roofed houses, built flush with the narrow sidewalks; in the unattractive square-cut doorways and windows with their iron gratings, giving the impression of a cell. Where the houses are more pretentious and some attempt is made to lessen the severity of design, the iron gratings are rather ornamental, and the effect is not unpleasant. Graceful outlines seem to have been reserved for the Government buildings and cathedral. The color scheme, the interestingly narrow cobble streets, and the plaza with the cathedral fronting it, neutralize, in some degree, the plainness in architecture. The town in white would be unpicturesque; in pink and blue it is interesting for a day at least. The interior arrangement of the homes of the higher classes is in delightful contrast to their exterior plainness. Every square or home of pretention has its courtyard or *patio* with its abundance of plants and flowers. The effect is extremely pleasant. The furnishings are often elegant, and the characteristic high ceilings lend a distinct charm to the apartments. The three hotels at El Fuerte have their courtyards with their foliage; the rooms, thick-walled and cool, surrounding them. The floors are of brick, which also makes for coolness. The method of cleaning these is to sprinkle them with water and brush them with a coarse rush broom—a backbreaking enterprise. Because of its dissolving effect on the brick, washing them is not countenanced.

The cooking is good, particularly if the appetite finds zest in Mexican dishes. Cereals do not long remain wholesome in the tropics, and to this, in part, may be attributed the absence of breakfast foods. Pastry depends on stoves, and because of their absence, cake and pie are seldom in evidence. More meat courses, therefore, are indulged in to engage the attention, always terminating—breakfast, lunch, dinner—with the national dish—beans. A little jelly and sweet bread make up the dessert. At one hotel, where are a few permanent American guests, the menu, owing to the presence of a small stove, is a little more elaborate. The rate charged, ₱2 for board, is very reasonable.

The town has its electric lights, and the steady current suggests ability in the engineering department of the plant. It is refreshing to enquire about the climate in the semitropics. The inhabitants—native and American—particularly the land promoters, will lie about it with cheerfulness and a healthy assurance. It is excellent, señor, especially in winter it is excellent. When malaria is mentioned, the suggestion is received with a shrug—pooh! And yet, sooner or later the inevitable happens. On one trip, going through, I found five cases of *calenturas* in one hotel, three Americans and two of the daughters of the lady of the house being the victims; all of them in the throes of alternating currents—arctic and equatorial. To the credit of the place, be it said, mosquitoes of the *Anopheles* breed were little in evidence, and that scourge of foreigners, the small black fly, seemed to be entirely absent. The water system in use is of an antiquity antedating the advent of the Spanish pioneers. The supply is brought to the dwellings in canvas sacks, on burros. A writer in the *Mexican Herald* describes the burros of El Fuerte as "living under water." That they are living under difficulties is evident from the sadness and distressing mournfulness of their appearance.

The water front, when business is thriving, is interesting. The burros are driven into the river and each boy hustles to fill his sack, dipping the water with a small bucket and pouring in at the top. In the haste of loading, half of the water flows over the burro; that, of course, being a small matter. A small horn at the bottom serves as a plug to the outlet for discharging the cargo. Whether the water be red or white, or of a limpid clearness, into the sack it goes at five *centavos* the sack.

A little farther down the stream a long line of women are seated on the banks and beach, sousing and wringing the clothes or pounding and rubbing them on the worn surfaces of the larger rocks. A few pretty women may be seen among them, but none beautiful. Early in life these women tend to *corpulencia*, then adieu, *la figura hermosa*. Addicted as they are to washing, eternally washing clothes, there is among them an uncleanly superstition, that washing the face and hands in the early morning will make them ill. The origin of this unhygenic creed can not be determined. Some 'medicine man' among the Indian tribes of the waste places may have promulgated the doctrine. *Muchas platicas* (gossip) and many a jest and laughter break with the wavelets up and down the river front. Seafoam and soap-foam meet and mingle and eddy round the bodies of the little brown shavers splashing in the river.

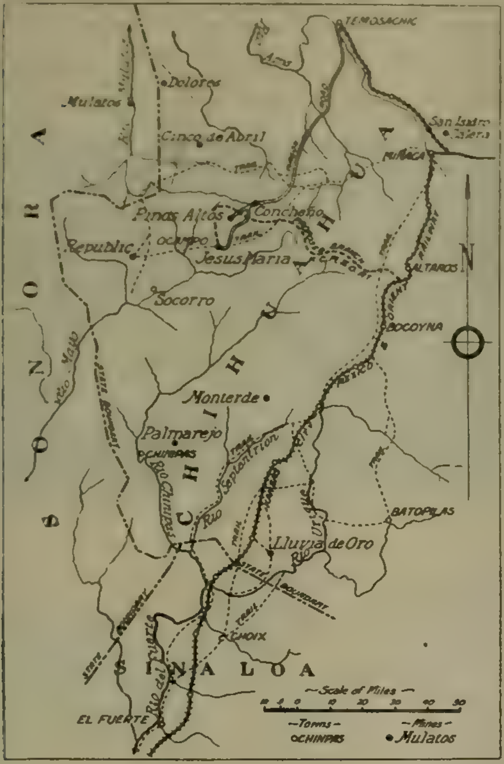
You may voyage upstream to the San Miguel and above to the Urachi, and beyond to the Verde, where the Tarahumare Indians dress in visions; something on similar lines may be found being enacted each day almost, decreasing in importance as the Indian encampments on the river increase. Into the beautiful river, at all seasons, goes the refuse—soluble and insoluble—from all the villages along all its banks. In times of flood, dead horses and dead cattle jostle together in their merry journey to the sea, traveling swifter in death than in life. The red on its face, it is said, is the blushing tinge it receives when passing the Batopilas virgin mineral belt above San Miguel. Small wonder is it that the roaring of the troubled stream may, at times, be heard for miles along its course. The concentrated product, taken inwardly, would not, in effect, differ greatly from that of the tailing solution flowing from a cyanide plant, but diluted as it is, it has a flavor that, to the thirsty, seems divine. The advice of physicians to boil the river water when used for drinking goes unheeded. The town has its plaza, with its abundance of plants and flowers. It is the preëminently charming feature of Mexican life—the plaza—with its flowers and shrubbery and foliage, the bandstand in the centre with its music, and the evening promenade of fashionably dressed people.

Good mules and a good mozo are important factors in the success of an expedition in the Sierra Madres. With such a combination to begin with, a host of evils are avoided. Dreams and slumber of the sweet variety attend the man whose *bestias* are in good trim. A few days, a week if necessary, is time well spent in the finding of decent saddle and pack animals. Horses are seldom used in Chihuahua or Sinaloa, and owing to the heat and long journeys burros are somewhat tedious. There are, usually, a number of corrals in the town or at the nearby ranches where mules can be purchased. The commission merchants usually have animals for sale. I had the good fortune to find excellent animals at the San Lucas ranch, near Las Casas Viejas, on the trail to Calabacillas. If a person's experience with mules has been limited, or if his Spanish is on the same footing, it will be found most satisfactory to have a friend along whose accomplishments include both. At the corral or ranch, or if brought to your hotel for inspection, the animals, you will be informed, are perfect specimens of their kind. All the virtues resident in mules have their abiding place in the pack before you. Whether or not you have previously engaged in a horse trade, you are aware of the ethics current among some of the votaries of the profession and what happens when trading begins.

A few miles ride on the saddle animal that looks good to you is advisable; after which you may prefer some other mule. Their sides should be examined for old sores. These old pack or saddle sores are very hard to heal, and although scarcely noticeable after a few months rest, often develop after the first day's packing or riding, if not attended to. When the mules have been brought to the hotel corral, the mozo should be instructed to wash their backs with soap and hot water, after which a bath of salt and water is advisable; the effect of the latter being to toughen the skin. Frequent washing and bathing for a time may prevent the recurrence of an old sore, besides insuring against new complications. The standard remedy carried by mule-train conductors, for saddle sores, is beef tallow, in which a little bluestone (copper sulphate) has been mixed. It has the virtue of quick healing. Too heavy blanketing, owing to the heat, is harmful, but the other extreme is worse. No matter how trustworthy the mozo may be, your personal attention should be given to seeing that sufficient blankets are provided and that the *aparajo* is plentifully stuffed with fine, light hay. Inattention to just one of these details resulted in my having to lead a pack mule six weeks while his back healed, hiring another to do his share of the packing. Good saddle and pack mules cost from ₱60 to ₱100.

The mozo should be a fairly good cook, although a highly artistic sense in that line is not always desirable. In the presence of a chef of distinction, saturated with a high art consciousness, the humble Mexican bean would shrink to nothingness. If you are in favor with the gods, you will know it by the mozo's refusing to look upon the mescal in the half-bottle. A word about this Mexican product. The mozo *par excellence* that is, the mozo of the mine manager and engineer, is a distinct prototype of his class. The northern Indian approaches him in one qualification only—that of guide. Compared to him the latter is slippery and unreliable. A Shoshone, or Piute, if he took it into his frowsy head, might leave the camp on the desert, miles from water, without so much as an adieu, or a word of warning. Centuries of peonage has impressed the peon with the idea of dependence, and a consequent respect and loyalty for his superiors. It is not an uncommon thing to send them for money, sometimes long distances. While in a district in southwestern Chihuahua, I had occasion to send to get a draft cashed. The manager of the mine at which I had stopped, needing currency, sent one of his mozos. The trip took four days, and the man had over $1000 with him on his return. At the same time another mozo was sent quite a distance to buy corn, carrying with him $500. Later, when I wished to hire one of them, I was told that under the system of peonage in vogue, I could not take him with me without the consent of the manager, to whom he was in debt. This trait of loyalty is significant, in view of the fact that the foreigner, especially the *gringo*, is looked upon by Mexicans generally, and by the higher classes particularly, as one to be 'worked.' In his high sombrero and white cotton pants rolled to the knees, shoeless, sockless, this sandalled son of the tropics has elements worth cultivating. Neither heat nor cold seems to affect his perennial good nature. I stood with one on the crest of the Sierra Madre at 2 a.m., under a small strip of canvas, hurriedly thrown over a rope stretched between two pines, with the rain pelting us unmercifully. We had gone to sleep under the brilliant illumination of the southern constellations and were slapped awake by heavy drops of rain in our faces—the forerunner, in these altitudes, of a deluge. Two hours later the brawling furies of the night had passed, and Orion, again resplendent, looked down on two sodden and shivering *hombres*, one of them apparently saddened, the other a grinning Mexican mozo. Initiative is not his. Rest assured if foresight is necessary, someone other than the mozo must possess it. His wages are from ₱1 to ₱1.50 per day with food. While not munificent, they suffice to impress him as being a rich man compared to his brother of the hoe, who is paid from ₱6 to ₱8 per month, with a small allowance of corn. But note the effect of a northern civilization, when he evolves to a certain point, he begins to lose in efficiency. This period in his culture is noted by a slight acquisition of English, and a desire to clothe his protesting feet in leather. When, finally, he becomes saturated with modern impulses, that which made him desirable has vanished and the fellow's occupation is gone. It was such a product that I had with me for a time. He talked volubly on Chartreuses, Vinos de Francia, Canadian Club, etc. He had submerged statistics and unholy descriptions of every town we stopped at over night. On the trail he wore *guaraches* (sandals), but carried a pair of shoes in his pack. He explained that *guaraches* were not allowed on the floor of some dance halls, and he wished to be prepared for any fandangos that might come his way along the trail.

The matter of supplies for the Mexican trail is one of easy arrangement. The small towns of the mining districts, through which the main trails pass, carry fair stocks of provisions. For instance, in traveling from El Fuerte to Morelos in Chihuahua, at least five supply points along the route can be utilized. This permits of light packing, an important matter when affairs are urgent. The more desirable things, such as coffee, dried beef, and rice, should be purchased at the railway towns; the best is not always sold in the interior. When the semi-tropics are reached, you bid adieu to cereals. Quaker Oats is sold at a few stores, but, owing to insects, is not desirable. Dried fruits suffer in the same way. Canned stuff, because of its weight, is out of the question on the Mexican as well as on the Alaskan trail. Potatoes are not grown extensively; for that reason few stores handle them. Those for sale are little larger than marbles. The price of bacon varies with the temperature; the shrinkage, due to the heat, being met by an advance in the price per pound, thereby making it an unpopular article of commerce. It is not easily obtained in the interior. As for pork, you will have none of it if you are a wise *gringo*. Eggs may, by diligent searching, be found at the ranchitos; the supply is uncertain. Cheese, beans, dried beef, and rice are always obtainable. The necessity of a plentiful supply of lard will become evident as the journey progresses, and a can with a tight fitting cover will prevent its anointing the pack. The *Mujeres* will look at you askance if a multitude of grease is not forthcoming, wherewith to fry the pounded jerked beef. You may carry flour and a small Dutch oven, but the chances are these will be dispensed with, and you will find yourself flirting with the native *tortilla*, the cornbread of the inhabitants. Things that add weight to the pack are soon discarded. A good appetite and a better imagination are aids in acquiring a taste for *tortillas de maize*, or *tortillas de harina*. The former are in vogue always in Chihuahua; the fashion in Sonora inclines to the latter. The simple life is in evidence largely on the Mexican trail, and some profess to enjoy it, for a time. A year or so of its simplicity, mingled perhaps with a bit of malaria, relegates it to the nether world, or some such locality.



PART OF MEXICO.

In regard to the pack: the standard weight of the tropics is 300 lb., and the day's journey is 12 miles. Therefore, should you wish to travel 25 or 30 miles per day, the pack ought not to exceed 150 lb. Two shallow boxes in which to carry the grub and cooking gear; a cot and a blanket; a quilt in addition for the winter months; a sack wherein to carry a change of garments, and a tarpaulin are all that is necessary. A mattress, because of its bulk, is a nuisance; the large palm-leaf saddle blankets are an excellent substitute. In winter the ground is preferable to a cot, as the wind has less surface to work on. A tent is seldom used, because of the necessity of stopping each evening at some ranch to purchase *sacate* and corn for the mules. The people, as a rule, especially those of the interior, are very kind, and an invitation to sleep in the *portale* is always extended. Even when camping in the open a tent is seldom raised. A stout tarpaulin answers the purpose admirably. Mosquito netting, a generous supply of quinine, and plenty of small change are indispensable. If it is not advisable to carry much currency, certified deposit checks of the Banco de Sonora, or the Banco de Minera, in the sums of ₱10 to ₱100 each will be found most convenient. These deposit checks are accepted at the mining agencies, where Wells-Fargo money orders or American bank drafts are refused.

PATIO OF THE ITURBIDE.

They are accepted readily at the stores at their face value for supplies, and can usually be cashed in the interior, less a small discount.

Two wagon-roads lead out from El Fuerte, one traveled extensively by those heading for the districts tributary to the El Fuerte river—the Lluvia de Oro in particular. The more easterly route is taken by those who wish to reach the Calabacillas or Morelos districts in Chihuahua. The first mentioned road passes through Choix, a journey of 15 hours from El Fuerte, and ends at the Mesa Colorado, from which point the districts are reached by trail. Choix is the local supply point for an extensive mining area, embracing in part the territory through which the El Fuerte river and the surveyed route of the Orient road passes. It is pleasantly situated in a small valley encircled by vari-colored rhyolite and andesite hills. Granite is much in evidence along the road from El Fuerte and east of the river to within a few miles of San Miguel. The high range twenty miles north and east of the town, over which the old Batopilas trail leads, is composed of that rock. Much of the eruptive formation overlying the granite is, apparently, of shallow depth. East of San Ignacio, where erosion has been particularly active, many dikes of diorite, andesite, basalt, and rhyolite may be seen cutting the granite. The contacts, although discouragingly barren in this vicinity, should not be interpreted unfavorably, as important orebodies have been opened along diorite intrusions in granite a few miles east of this point. The first and greatest mining boom of Mexican history, that of the seventeenth century, found a fertile field in this part of the republic, particularly in the great Alamos and Arteaga districts to the east and north.

A remarkable event of the period was the plunge of the Church in mining. Soul-saving and gold-saving were the ecclesiastical rivals of the boom, the latter, for once, being sanctified and blessed. With her sacerdotal robes tucked tight about her, the Church waded deep into the mysteries of metallurgy, and with brilliant financial results. To its spiritual astonishment, the Altar found itself in league with the *patio*. Mingled with the odor of burning incense from swinging censers, were the penetrating fumes from cupelling furnaces and the unholy smell of retorted amalgam. The State seconded the Church nobly in its exploitation of the mines and the natives. Their efforts were confined to skimming the cream, and that they succeeded is evidenced by the recorded production of those days.

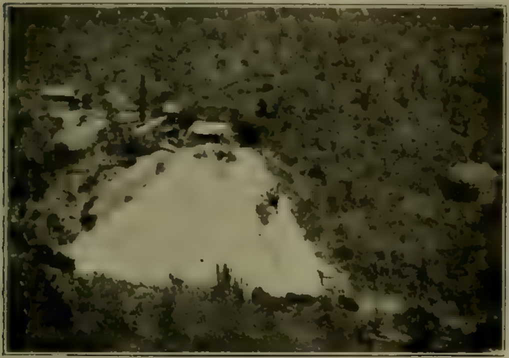
Many gold and copper prospects are being opened at this time in the Choix district, and the completion of the Orient road should greatly encourage development in that part of the country. The centre of attraction toward which all things in the vicinity of the El Fuerte river gravitate, apparently, is the Lluvia de Oro mine. Much has been written about this property, its great richness, the discovery of the vein, etc. A region of romance surrounds it. Its atmosphere has all the lure of the most fabled districts of Mexico, with their legends of lost mines, rich float, etc., but nothing in its fiction is more alluring than the fact of this 'Shower of Gold,' as it has aptly been named (Lluvia de Oro), situated as it is high above the river at the top of the mountain. No legend is more fascinating than that of the genesis of this deposit, deep amid the sedimentaries of the earth; of the mighty forces that wrought in its production; the subtle chemical skill at work in its subterranean laboratory, transmuting, combining, crystallizing its atoms; and, finally, the titanic uplifting of it from its Cretaceous bed and leaving it a mile above the level of the sea, its riches open to the Indian or peon. Every traveler passing through hears the story of the Gloria Pan, a mine with the greatest recorded production of all the lost mines of Chihuahua. It is supposed to be somewhere in this vicinity. The great richness of the Lluvia orebody, between limestone and andesite, suggests a similar deposit in the same locality, such as the Gloria Pan must have been, but one exhausted centuries ago.

Forty miles upstream is the little village of San Ignacio. The Urique and Batopilas trails meet at this point. Following a trail east along the little creek that empties into the river near the village, a ride of four hours brings us to the *antigua* settlement of Guadalupe Viejo. The ruins of an old church and numerous adobes suggest that centuries ago quite a population was established here. A few Indians and Mexicans are encamped near the ruins at present. The oldest inhabitant of the district knows nothing of the history of either mine or *pueblo*. The débris of *patios* and arastras may be seen at the foot of the mountain where water was available. A broad trail, nearly obliterated in places, leads to the summit of the mountain. A short distance below the summit, on the east flank, are the workings, some of which are inaccessible, of the Guadalupe Viejo. The vein is in rhyolite and where observable is four feet in width. The size of some of the workings suggests that the crevice rock was of a milling grade. Erosion has carried away the hanging wall rock for some distance, showing the steep dip along what seems to be the stripped foot-wall of the vein, a sheer drop of 2500 feet to the canyon below. This *antigua* is the lost Gloria Pan, according to some reliable authorities. Their opinion is based on certain geographical features that they claim tally with the recorded description of the *antigua*.

The territory lying between the Lluvia de Oro and San Ignacio offers little inducement to prospectors, the country having been capped by several flows, tuffs, etc. Many mining men following the trail up the river become disgusted with the appearance of the region and turn west. Had they prolonged their journey a day or two they would have reached a very interesting part of the great West Coast mineral belt, along the trend of which are situated some of the largest producers in Mexico. There is no hesitation in regard to it when once it is entered, as the country changes rapidly from uninteresting granite and rhyolite areas to a greatly oxidized region, some of which is scarlet in color, so impregnated is it with iron oxide. In its southerly trend this mineral belt includes the Artega, Batopilas, Calabacillas, and other producing districts. The Teneriba river empties into the San Miguel near the village of that name, and much of its crooked wanderings for thirty miles are within this zone. Many *antiguas*, some open to depths of 400 feet, bear witness to the activity of the early Spaniard. Except at La Dura, no mining operations are in progress in all this vast region, much of which is worthy of investigation. Deep-seated rhyolite, andesite, and other eruptives are the prevailing rocks of the districts.

The trail to San Jose de Gracia, Calabacillas, and Morelos from El Fuerte, lies by way of Chinabampo and Yecorata. The trip to Chinabampo is quite sufficient for the first day's journey, if the outfit requires breaking in. No mining is being done in or near the country through which the trail passes until Yecorata is reached. Some of the officials of the Orient railway are operating a large low-grade vein at the latter place, on a bond and lease from Robert Duff, a one-time superintendent of the Batopilas. All good Americans stop for a chat with the old gentleman in passing, when affairs are not urgent. Schist and granite are much in evidence through the district, overlain to the east by extensive areas of rhyolite and andesite. The old trail to San Jose de Gracia, now seldom traveled, branches off at this point. Some dredging is in progress a short distance above Yecorata. Along the trail to Calabacillas at Las Casas Viejas, El Reparo, Oro Fino, feed for the mules can be purchased, and, in a modest way, meals may be had. Little of interest in a mining way is noted until Placers is reached, as the country between El Reparo and the latter place lies between mineral belts. Above Placers, at the top of the mountain, is the mining camp of San Ignacio, owned by Philadelphia people. Some fine-looking veins are being developed to the point where a reduction plant will soon be advisable. The view from the camp is one of extreme beauty. There are situations in the Rocky Mountains that surpass it in the rugged grandeur of ranges and peaks that rise far above the line of timber, but to the magnificent sweep of this scene is added the peculiar charm of tropical light on the horizon unknown in the northern ranges.

There is little in a mineral way over which to enthuse in passing Oro Fino, as the place is handicapped by the memory of a ₱200,000 failure. Altogether, about four days are required to reach Calabacillas from El Fuerte. The trail to Reparo is an easy one, broad, and free from stones, after that it is a continuous series of mountains and canyons. As at the Guadalupe de los Reyes, the Rosario of Guadalupe y Calvo, the Jesus Maria, and at practically all the west coast producers, so at the Calabacillas the presence of andesite has played an important rôle, evidently, in the formation of the orebodies. The mine bears the same relation to the district in which it is situated as the Lluvia de Oro does to the territory in its vicinity; it is the luminary whose light is reflected in greater or less degree in the satellites surrounding it. It is classed among the world-beaters; an inelegant term, but one used at times in speaking of the elect such as Palmarejo, El Tigre, and Promontorio. Several ore-shoots have been opened on the vein, in width from 12 to 75 ft., in length from 60 to 100 ft., the average value throughout the mine being about $15 per ton gold. The ore is treated in a 20-stamp mill, by amalgamation and cyanidation, the tailing from the plates assaying about $3. It is a silicified rhyolite breccia, closely resembling some ores found in the same formation in Arizona and Nevada. This similarity in ores, noted now and again in widely separated rhyolite and andesite areas in the Cordilleras, may be attributed, perhaps not incorrectly, to their close relationship, as belonging to the period of volcanic activity which produced the world-chain of rhyolite and andesite rocks, its trend being along the Andes, the Cordilleras, the Aleutian Islands, and Japan.



GUADALUPE MINE.

Morelos is about one and one-half days' journey from Calabacillas. The trail is decidedly uphill at the start, but has the virtue of side-winding until the top is reached, when it follows the *cumbre*. It is uninteresting until nearing Potrero, as the country is capped by late flows, breccias, and tuffs. Then, rapidly, as on the El Fuerte river below San Miguel, the tiresome gray of the rhyolite gives way to the deep cream-brown and red tints of iron oxidation. The appearance of the region improves steadily as Morelos is neared. Whoever has looked down for the first time on the scarlet hills of Batopilas or Morelos, without a geologic thrill, is dead, mineralogically at least. The deep red warms the heart, as it warmed the hearts of Creel and Sheppard many years ago. Morelos is dead at present, but the evidence of its past energy is seen in the extent of the town, now falling to ruins. A few days spent in the surrounding hills convinces one that a resurrection is not improbable, and that sooner or later the old mineral will resume something of its former activity. The genial mining agent, Manuel Perez, kindly permitted me to look over the old account books of one of the properties operated by his family, and the record of two claims —one of them the San Anastasia—showed a production of over ₱30,000,000, principally in silver. The ore occurred along an intrusion of diorite in granite. When the diorite pinches along the strike of the vein, both vein and mineral content rapidly diminish, one pinching, the other petering out. The property was developed by shafts, and when water became bothersome operations ceased, after the reserves were exhausted.

There are many old and valuable mining claims lying idle in the district, some of them the property of Jose Creel and Alexander Sheppard. The trail to La Dura follows the river bed of the creek that flows through Morelos to the Tenoriba river, then along the river bed for about 15 miles until La Dura creek is reached, when it follows the latter to the camp. The little town is pleasantly situated high in the Sierra Madres and is surrounded by rhyolite hills. Many dikes of diorite, andesite, basalt, and other eruptives are found in the district, and many large and well defined veins have been developed by the Dolores company, the only mining company operating in that district. A roasting-furnace prepares the ore for further reduction in the crushing and cyaniding plant. The capacity of the plant—a Huntington and Little Giant mill—is out of all proportion to the size of the veins, some of which are 20 ft. or more in width. Gold predominates in the ore, a fair percentage of silver being also present. Few foreigners pass this way, but those who do are received most hospitably.

The trail leading out of Morelos to the summit, traveling east, is conceded to contain within its lofty windings all the ingredients that go to produce climbing that may be classed as stiff.

Another that is decidedly to the fore among the steep ones of the Sierra Madres is the drop that occurs from the summit to the *arroya*, near the Tomnil mine in Durango, on the trail to Guadalupe de los Reyes. Besides these, the trail from La Dura to the summit, going west, may be safely matched as combining the salient characteristics of each, adding a distinctive feature in that its design and construction could only have been engineered by a Mexican goat.

TAJO MILL, ROSARIO.

Once past the summit the route traverses great forests of pine, sweet-smelling, shading the moss and grass carpeted trail; a paradise far above slippery rock-slides and uncomplimentary expressions. A journey of three and one-half days suffices to cover the distance to Guadalupe y Calvo. The trail passes through Las Cebollitas, a gold camp of excellent prospects. A slight detour is necessary to reach Los Angeles, where a Mexican company is operating.

An altitude of 8000 ft. confers upon Guadalupe y Calvo an ideal summer and winter climate. Its history is the history of the Rosario mine. The manner of the discovery of the Rosario vein was told me by Manuel Perez of Morelos, Chihuahua. It was the custom of some of the Morelos people who had learned of the existence of rich placers on what is now Rosario creek, to spend the summer months at this new resort in the mountains, thereby avoiding the excessive heat of Morelos, and, at the same time, rock out sufficient gold to provide against the winter months. As soon as the weather began to get chilly the party returned to Morelos. Several seasons were spent in this highly satisfactory manner before the possibility of finding the source of the gold was considered. The deep red and yellow of the Rosario outcrop, in contrast to the sombre shades of the adjacent rock, makes the vicinity of the lode conspicuous for a long distance. In addition, the hill was strewn with float, some of it rich, and the placer operations frequently required the removal of quartz boulders that lined the creek. Mexicans of the mining districts, as a rule, are considered good prospectors, but these were blind to the signs in the water beneath and in the earth above them. Only the failure to find gold, going upstream, where the creek diverges from the hill, induced them to follow where the pannings led—farther up the mountain. In this way Fortune clubbed them into discovering the lode, which at this point was 60 ft. wide and about 1200 ft. from the creek. Then followed the usual denouncements and operations of milling, by arastras and other simple means. Later the property passed into the hands of the Ochoa family, from whom it was leased by London and Edinburgh mining men. The boom that followed the development of the orebodies is referred to by the natives as "the days of the English." The population increased rapidly from a handful in tents to 12,000 housed in brick and adobe. Supplies were packed from Vera Cruz, the nearest Atlantic seaport, a distance by rail of over 1000 miles. Merchandise from Europe by way of Cape Horn, as well as from ports of the Orient, was unloaded at Altata, the gulf port on the Pacific, and shipped inland by way of Culiacan.

A prosperous Mexican mining town in action is rarely uninteresting. The varied hues in apparel and in the tints of the buildings, intersperse a wealth of color through the life of the town, and where the area is limited, as at Guadalupe y Calvo, the effect is more pronounced. The frequent arrival of mule-trains from Vera Cruz after a six months voyage, or from Altata, with their interesting cargoes, was the occasion for great enthusiasm and festivities not included in the church calendar. The trains often numbered 500 mules, and a band of music frequently escorted them in and accompanied them for a short distance on their departure. The musical cry of the *arieros* to their mules, "*andele! andele!*" and the din of yelling and shouts of welcome to the conductors and drivers, seasoned black on tropic trails, made a spectacle wholly unknown north of the border. Each Saturday evening a keg of *mescal* was set up in the street, but this was looked upon as a preface, merely, to the elaborate and often wild proceedings of the night and day following. The production of the mine became so important that the Government established a mint about the year 1840. The walls of the buildings still stand, a reminder of former prosperity.

The negotiations with the Ochoa family for a new lease failing, the English departed for Vera Cruz and London. Under their management of the mine, the mint alone recorded a production of ₱50,000,000. With their departure the luck of the camp vanished. Disaster attended the efforts of the Ochoa family until finally they abandoned the property. The dump, at that time considered too low grade to handle, consisted of nearly 200,000 tons of ore, valued at $10 per ton, besides large reserves in the mine. The efforts of the new locators were confined to 'gutting' the mine and sorting the dump. After they had satisfied themselves along this line, they sold to a Texas syndicate. A small stamp-mill was installed, but the operations of the syndicate were unsuccessful and the mine was closed. Another turn of the wheel and the property is again in the hands of its friends the British, represented by the Western Mining Co. This company is erecting a 200-ton plant to treat the ore of the dump, as a beginning. Heavy faulting and capping of the rhyolite, the formation surrounding the district, limits the mining area to about two miles along the strike of the Rosario lode, which lies between the andesite and rhyolite.

WHILE the report of the Geological Survey and the Director of the Mint recently issued shows that Montana's gold and silver production for 1910 was practically the same as in 1909, it is believed here that the gold production for the present year will show a large increase, together with the silver output.

Breckenridge Mining District

Breckenridge, like Leadville and many other mining districts of Colorado, owes the discovery of its mineral wealth to that wave of westward emigration which in 1859 surged toward Pike's Peak and broke along the eastern flank of the Front Range. A detailed study of the district was recently made by F. L. Ransome and E. S. Bastin, geologists of the U. S. Geological Survey, and the Survey has just issued a report on the district by Mr. Ransome. This report covers an area of about 45 square miles situated in Summit county, Colorado, 60 miles southwest of Denver.

The rock formations of the Breckenridge district differ from those at Leadville and Tenmile in that the thick body of Paleozoic sedimentary rocks is absent, formations of later (Mesozoic) age resting directly on a base of pre-Cambrian rocks. During the ice age there were two advances and retreats of glacial ice. The earlier glaciation is represented by terrace gravels and by what has been called hillside wash; the later one by moraines and low-level gravels or valley trains. These later glacial deposits occupy the bottoms of the present valleys to a depth of 25 to 90 ft. and are yielding an important amount of gold to dredges each year.

The total gold production of the district is estimated by Mr. Ransome at somewhat less than $20,000,000, derived mostly from placers. Breckenridge in the past has yielded ores of varied kinds and richness, from the native gold of Farncomb Hill on the one hand to the zinc ores of the Country Boy mine on the other. Much of the output has been partly oxidized argentiferous lead ore, which, like the other ores and concentrates of the district, averages about $25 per ton in value. The deposits are principally narrow fissure fillings laid down through the agency of thermal waters and gases either given off or made effective by slowly cooling masses of deeply buried igneous rock.

Mineralogically the Breckenridge district, although noted for the occurrence of crystalline native gold in filiform and leafy aggregates of remarkable delicacy and beauty, is not of great or varied interest. Mr. Ransome concludes that the district does not give definite promise of any general and permanent revival of deep mining. Pay-ore has been found only within about 400 ft. of the surface, so that the future depends largely on the discovery of new bodies. At present gold dredging is the chief economic resource of the district. In 1909 four boats, with a capacity of 12,000 cu. yd. in 24 hr., were operating on the low-level gravels. An area sufficient to perpetuate this industry for ten or possibly fifteen years is available, but in addition there still remains much low-grade bench gravel that may some time be washed or dredged with profit.

California Vanadinates

While analyzing ores of the Camp Signal mining district, in April 1911, R. O. Hall discovered the existence of vanadium ores in California. Samples of the mineral were sent to W. T. Schaller, who has published in the *Journal* of the Washington Academy of Sciences the following: "Some samples of vanadium ore, sent to the Survey by A. L. Lombard and J. F. Main, of the Dirigo Mining & Milling Co., of Los Angeles, California, proved to be coated with a deposit of cupro-descloizite. The associated lead minerals are cerussite and vanadinite from which the cupro-descloizite seems to be derived. The locality is given as Camp Signal, in San Bernardino county, California. A qualitative chemical test showed the presence in quantity of lead, copper, zinc, vanadium, and a little water. A direct quantitative determination of the vanadium gave 21% of V_2O_5."

With the deposits of vanadinates, wolframite, hübnerite, and ferberite occur plentifully. The claims (eight in number) are situated ten miles northwest of Goff's, a station on the Santa Fé railroad.

Comparisons of Fuel Costs in the Dredging Field of Alaska

By E. S. Rust

In the construction and operation of gold dredges in the Alaska field the fuel problem is sometimes of vital importance. Electrical power at 2½ to 3c. per kilowatt hour is by far the most satisfactory if the dredge property is so situated that the cost of line construction from the power site to the dredge is not too great. For one small dredge it can readily be seen that great expense cannot be incurred in installing a long power line, but if the company building the dredge or dredges be large enough, or if there are other operating companies in the near neighborhood, it may prove advisable for several to consolidate for the installation of a power line or electric plant, provided the necessary water power be available. Should electrical power not be available, and the erecting of a power-plant not practical, we have to consider coal, fuel oil, wood, or gasoline as fuel for generating power. In some localities it is only necessary to consider two or three different kinds of fuel. At Nome there is no wood to be had at any price, and in that neighborhood distillate is found to be the most practicable for the 2½ or 3½-ft. boat, digging from a depth of 10 to 25 ft. Coal can be obtained from Seattle for about $21 per ton.

The Yuba Construction Co. has installed gas-engines on dredges operating in the Alaska field, and has proved their efficiency for handling anything but frozen ground, which up to the present time has not been dug profitably by dredging. Fuel oil, though cheaper than coal, has one serious disadvantage. No matter with what care it is handled, it is practically impossible to prevent some of it from entering the dredge pond and getting over the tables, thus interfering with the amalgamation of the fine gold to a great extent. The non-freezing qualities of distillate is also a point to be considered in comparison with fuel oil. At Dawson and vicinity there is a poor grade of native coal which may be bought at prices ranging from $15 to $18 per ton. Freight rates on coal from Seattle almost prohibit its use as a fuel in that district and Fairbanks. Wood may be had at Dawson and Fairbanks in sufficient quantities, but owing to the cost of cutting and transportation to the dredge, some other fuel could probably be used to better advantage.

From freight costs and from information given by operators in the Northern field, the following table has been compiled, and may assist anyone contemplating the installation of a dredge in the Alaska field in solving the fuel problem for his conditions of work. These figures represent the costs at the three towns only, and transportation charges to the dredge sites, which vary with the seasons and the localities, should be added. It is obvious that these may greatly increase the total cost.

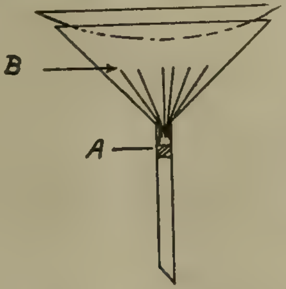
	Coal.	Fuel Oil.	Distillate.	Wood.
Nome	$17 to $21 per ton	$2 per bbl.	15c. to 21c. per gal.	
Fairbanks	None at present	$6.10 per bbl.	30c. per gal. *via* St. Michael	$12.50 to $15 per cord
Dawson	$18—poor native coal	$7 per bbl. in drums	32c. to 35c. per gal.	$12.50 to $15 per cord
Fuel equivalent	1 ton	116 gal.	29 gal.	2 cords
Fuel consumption per hp.-hour	8.7 lb.	½ gal.	⅛ gal.	20 lb. dry pine

COMPARATIVE COST OF FUELS IN ALASKA DREDGING FIELDS.

A Rapid Filtering Funnel

By H. Spurrier

The ordinary funnels used in analytical work may be made to filter far more rapidly than usual, by deeply etching lines from a point below the apex of the funnel to points forming a ring about two-thirds of the way up the sides, in the following manner: Coat the inside of the funnel with a layer of paraffin (containing a little turpentine or other agent to render it non-brittle) and allow part of the wax to run down into the tail and form a solid plug about 5 mm. below the apex of the funnel or well below the lowest point reached by the filter paper.



RAPID FILTERING FUNNEL.

Scratch six or eight lines in the wax coating extending from the point *B* to the wax plug at *A*; now fill the funnel to a point above *B* with hydrofluoric acid and allow to stand 25 minutes; then pour out the acid into another funnel prepared as the first, and so on until as many funnels have been prepared as required. The funnel should be covered with a waxed beaker cover. The wax may be removed by hot water and the deeply etched grooves cleaned out with the point of a mechanic's scratch-awl or other suitable tool. These grooves are not large enough to allow a filter paper to be broken by the stream from a wash bottle, but afford efficient channels for the filtrate to flow down. The funnels may be used with the filter cone and are especially valuable in filtering gelatinous precipitates such as alumina. The speed of filtration is increased by this means to about two and a half times the normal rate for a funnel not so treated.—*Jour. Amer. Chem. Society.*

Gold Dredging at Paracale

Press reports from China state that the Philippine Dredging Proprietary, Ltd., a Melbourne concern, of which J. W. McWhae, J. G. Aikman, and A. B. Johnson are directors and A. F. Showers is the secretary, has purchased the dredges and mill equipment of the New Zealand company now operating in the Paracale district, Philippine Islands. By the terms of the agreement the former controllers, Frank B. Ingersoll and a number of associates, are to receive 2% royalty of the earnings of the new company. The reports on the property for purchasers by J. W. McWhae and J. Bertinshaw state that the 800 acres of dredging ground acquired constitute a valuable property, provided that adequate plant is installed to treat the large extent of high-grade alluvial river beds stated to exist. The installation of dredges of large capacity, fitted with close-connected buckets—the whole plant designed so as to get the overburden away quickly—is expected to quadruple the yields being obtained with the present appliances at a relatively small increase in the aggregate working expenses. On the Paracale claim 64 bore-holes averaged 7 gr. of gold per cubic yard of drift; the Melville & Fingal claim averaged 10½ gr. from 13 holes bored, and the Nueva California averaged 13¾ gr. from seven holes.

The Refining of Copper

Eight plants handle the refining of upward of 1,000,000,000 lb. of copper in the United States annually, according to the *Boston News Bureau*. When all plans have been carried out, the Guggenheims, with their three refineries, will lead in capacity with a total of 480,000,000 lb. per year. At the moment there is being sold through their sales agency approximately 340,000,000 lb. per annum. The three Guggenheim refineries are owned by two of their companies. American Smelters Securities Co. owns the Baltimore plant, which at the time it was purchased had an annual capacity of 144,000,000 lb. Early in 1910 this had been increased to 240,000,000 lb. per year, and Daniel Guggenheim went on record some time ago as saying that its ultimate capacity would be 288,000,000 lb. The Smelters Securities company also owns the Tacoma smelter and refinery, which has a capacity of 24,000,000 lb. per year. The Perth Amboy refinery is owned by the American Smelting & Refining Co. It has a capacity of 168,000,000 lb. per annum. Thus for the three Guggenheim refineries an ultimate capacity of 480,000,000 lb. yearly should result when all improvements and additions have been completed.

By combining the capacities of the Raritan and Boston & Montana refineries the Amalgamated interests have a yearly total of 456,000,000 lb. in comparison with Guggenheims future total of 480,000,000 lb. The Laurel Hill refinery, owned by the Nichols Copper Co., has long held first place with regard to capacity, or at the rate of 396,000,000 lb. per year. This place has been usurped by the Raritan refinery, formerly owned by the United Metals Selling Co., but now controlled and operated by the International Smelting & Refining Co., its capacity being 408,000,000 lb. per annum. The Anaconda company operates a refinery in Montana with a capacity of 48,000,000 lb. yearly.

In the following table increase in capacity of the various refineries in the past three years together with present annual capacity is shown:

Plant.	Annual.	Monthly 1911.	Monthly 1910.	Monthly 1909.
Raritan	408,000,000	34,000,000	27,000,000	24,000,000
Boston & Mont.	48,000,000	4,000,000	4,000,000	4,000,000
Nichols	396,000,000	33,000,000	33,000,000	27,000,000
Guggenheims ..	*480,000,000	*40,000,000	25,000,000	12,000,000
U. S. Refining..	180,000,000	15,000,000	14,000,000	10,500,000
Balbach.........	30,000,000	2,500,000	2,500,000	2,500,000
Total	1,542,000,000	128,500,000	105,500,000	80,000,000

*Ultimate capacity.

Selling and refining of copper has always gone, for the most part, hand in hand. The United Metals Selling Co. handles practically all of the Raritan and Boston & Montana output, which at full capacity would total 456,000,000 lb. The Raritan plant, under recently acquired contracts, has been treating the product of three companies, Miami, British Columbia, and South Utah, which it does not sell. All other copper refined by International Smelting & Refining Co. is marketed by the United Metals Selling Company.

The Nichols Copper Co. does not maintain a selling agency, its product being sold by the American Metal Co. In addition to the Nichols output the American Metal Co. operates the Balbach refinery. The best customer of the Nichols company has for years been Phelps, Dodge & Co., with about 135,000,000 lb. of copper at current rate of operations. Phelps, Dodge & Co. alone of the big selling agencies, does not own a refinery.

A close working alliance has existed for some years between the United States Smelting, Refining & Mining Co. and the L. Vogelstein & Co. selling agency whereby the latter markets the output of the former. The Calumet & Hecla Co. owns and operates a small refinery at Buffalo where a portion of its subsidiaries' product is being treated electrolytically. There also the silver-bearing native copper of the Quincy company has been electrolytically treated for some time past.

The Lead Market

L. Vogelstein & Co. reports that the recent decline in the lead market took the trade generally by surprise. These are the first changes of note in desilverized lead prices since November 1910, though Missouri brands during the same period have fluctuated over a range of twenty points—from $4.22½ to $4.42½. Various reasons have been assigned for the decline, but it is believed that the smaller consumption of white lead due to the high price of linseed oil with resultant falling off in the paint trade, is chiefly responsible. Fear of possible tariff revision is another disturbing factor, and while admitting that one of the chief points of attack will be the lead schedule, the eventual success of efforts in this direction may be doubted. When the present bill was passed there was a strong fight to have the lead duty reduced, and in the bill as originally published the new duties were placed at 1c. on lead in ore and 1½c. on pig lead, but they were subsequently changed back to the Dingley rates. At the time these new reduced rates were in prospect the lead market was never less than $4 to $4.10 New York, based upon a price for soft Spanish lead of £2 (½c.) less than that now prevailing. Today's price is equivalent to $3.30 and the market is strong. Adding to this figure even a 1c. duty on lead in ore, the parity is 4.30c. New York. To import pig lead with a duty of 1½c. would cost in the neighborhood of 4¾ to 5c. per pound. In other words, even granted such a drastic revision of the tariff as above referred to, effects so far as this market is concerned are already discounted. In considering this phase of the matter, it should also be borne in mind that any diversion from foreign to domestic markets of lead made in this country from imported ore or bullion would probably result in higher prices abroad. As pointed out recently, stocks of foreign lead in bonded warehouses have been cut in half, in spite of which the European market has advanced, showing that this lead is needed in Europe. Assuming that this diagnosis is correct, the trouble will shortly be remedied, as buying against spring requirements must soon commence, and if painting has been put off this year, it only means an increased demand later on. That there is a good current consumption together with considerable confidence in the market, is shown by the heavy buying since the decline took place and this buying still continues.

ELECTROCHEMISTRY is the art of applying electrical energy to facilitating the work of the chemist. It is chemistry helped by electricity. It is the use of a new agency in accomplishing chemical operations, and it has not only succeeded in facilitating many of the most difficult and costly of chemical reactions, but it has in many cases supplanted them by quick, simple, and direct methods; it has even, in many cases, developed new reactions and produced new materials which are not otherwise capable of being made. A few examples will illustrate these points: Caustic soda and bleaching powder are made from common salt by a series of operations, but the electrical method does this neatly and cheaply in practically one operation; lime and carbon do not react by ordinary chemical processes, but in the electric furnace they react at once to form the valuable and familiar calcium carbide; carbon stays carbon except when the intense heat of the electric furnace converts it into artificial graphite.

THE UNITED STATES has long held first place as a manufacturer of asbestos goods, but the raw material for that purpose was freely drawn from Canada, at present the chief source of the world's supply. According to J. S. Diller, the production of asbestos in the United States is not only increasing in quantity, but improving in quality. The total output for 1910 was the greatest ever credited to the United States, being 3693 tons, valued at $68,357. This was an increase of 20% in quantity over the production of 1909, with brighter prospects for the future.

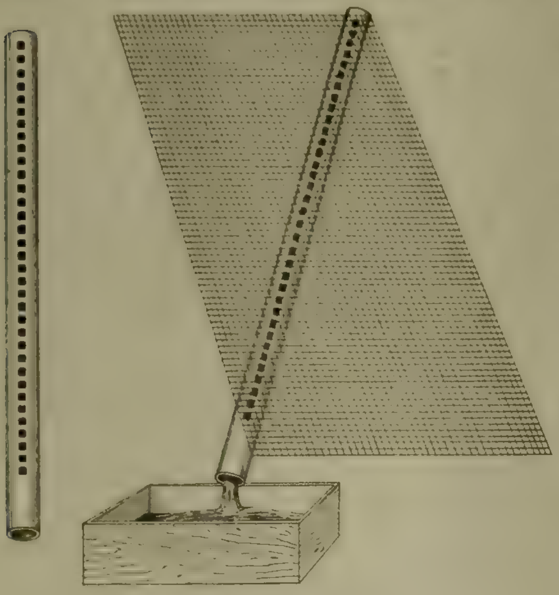
Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any letter is determined by its probable interest to the readers of this journal.

A Neat Sampling Device

The Editor:

Sir—While this method of sampling is not new, it may be used to good advantage for the sampling of mine screenings and may be made very cheaply. To construct the sampler, take a piece of ordinary 4-in. galvanized pipe, as used for ventilating mines and cut as shown in the illustration. Place this diagonally across and about 6 in. beneath the screen. The square holes in the pipe should be cut a little larger than the mesh of the screen used. If a ½-in. screen is used, the holes should be cut about 1 in. square and proportionately. Allow the end of the pipe to extend about 18 in. from the side of the screen and place a box underneath the spout to receive the sample. This may be emptied at the end of each shift, and a fairly accurate sample of the day's run will be obtained.



SIMPLE SAMPLING DEVICE.

MINER.

Rawhide, Nevada, October 18.

Aluminum

The Editor:

Sir—I beg to call your attention to an oversight on page 418 of your last issue. *Aluminum* should read *aluminium*. I know that most Americans spell it and pronounce it *aluminum*, nevertheless *aluminium* is the correct version and the one in use and accepted by the scientific world. The discoverer, Sir Humphrey Davy, in the beginning of last century called the metal *aluminum*, to be sure, but little was known about it, nor much use made of it, until the Germans seriously occupied themselves with this interesting and valuable metal seventy-five years later. They then gave it the name *aluminium*, which is the one adopted by all scientific bodies. No doubt you have heard of the Mannesman Brothers (Brüder) of Remscheid. I know them well—they are without doubt the greatest aluminium merchants in the world—and throughout their vast plants and works the word *aluminum* is unknown. All the standard dictionaries speak of it as *aluminium* and I remember very well that during a lecture on the subject while a student in Columbia College, no less an authority than the well known and popular professor, Charles F. Chandler, particularly called the attention of his students to the fact that *aluminum* was an American distortion and wrong version of the correct scientific name *aluminium*, and as a matter of accuracy, requested us to refrain from using it. Since your paper aims at scientific accuracy, you will no doubt accept these remarks in the spirit they are given.

JUAN FELIX BRANDES.

San Francisco, October 24.

[We are very glad to accept Mr. Brandes' remarks in the friendly spirit in which they are sent, but his conclusions can scarcely be so readily endorsed. The Standard dictionary, which is generally accepted as the standard of American usage, prefers the spelling *aluminum*, adding that there is great diversity of usage, and neither form has yet been adopted to the exclusion of the other. It was our privilege also to sit in the classes of that distinguished chemist, Charles E. Chandler, but our admiration for his profound knowledge and the fascination that he injected into lectures on what is too often but a dry science, did not lead us to adopt his practice in this regard. N. S. Shaler, an equally profound scholar and popular lecturer, may be quoted upon the other side, and T. W. Hunt, professor of English at Princeton, believes that *aluminum* is practically the accepted usage in America. That *aluminium* follows the precedent established by *sodium* and *potassium* is unquestionable, but when the attempt is made to pronounce the word the necessary alteration in the sound of the first two syllables almost eliminates the mental association with alum, the preservation of which was the chief reason for the devising of this method of naming elements. Use is the law of language, *aluminum* slips more smoothly from the tongue of Americans, and in this case, as in every other, we must be guided by what, in our judgment, is the usage followed by the greatest number of the well informed.—EDITOR.]

NO ESTIMATES of the amount of available iron ore in Canada have been made by any of the various governmental officials. In a report by C. W. Hayes on the 'Conservation of Natural Resources in the United States,' an estimate is made of the iron ores in the countries adjoining the United States. The estimate is there made of available ore as follows: British Columbia, 30,000,000 tons; Ontario, 9,000,000 tons; Nova Scotia, 4,000,000 tons; total, 43,000,000 tons. This is considered a sufficiently high figure for ore already known. At the same time the possibilities, and indeed probabilities, are so great that a much larger tonnage must be considered as likely to be found. The Lake Superior type of bedded deposit is known to occur in the extreme northwest of Canada in the Yukon territory and in the southeast in New Brunswick, a distance of 2800 miles. At numerous points between these extremes, Keewatin rocks of the great Archean shield are known to occur, and in nearly every case where these have been carefully searched the iron formation has been found. In far from all of these occurrences will the iron formation be productive of commercial ore, but there is every reason to expect that with careful and detailed exploration, many of them will. It is true that large areas at present are so far from transportation that they cannot be considered as possible sources of iron ore for years to come. The Clinton ore deposits, which yield such a large portion of iron ores of the United States, occur but to a limited extent in Canada and cannot be looked on as probable large producers. In Newfoundland, however, two steel companies have very large iron-ore reserves in beds of this type.

THE Standard Consolidated Tin Mines at Sandy Creek, by way of Charters Towers (Queensland), have commenced operation with about 30 men. A hoisting and pumping plant has been built, while the old stamp-mill is doing duty pending the construction of the complete plant. The building of a concrete dam is in progress.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

DENDRITIC markings are due to descending oxidizing solutions, and are chiefly manganese or manganese and iron stains.

CLAIMS which have been patented cannot be lost except through failure to pay the taxes upon them (when they may be sold for default), as the title conveyed by a U. S. patent is an absolute one.

PLACER is derived from the Spanish *placer*, which has the same meaning as the English term. *Placel* is the Spanish term for a sand-bank, and both terms are probably derived from *plaza*, a place.

RUTILE, or titanium oxide, was produced in the United States last year only at and near Roseland, Virgina. No rutile was imported, but one American company exported it in considerable quantities.

SERVICES of a watchman on an unpatented claim can only be allowed where improvements exist that require watching. When machinery or buildings require watching such service may be allowed as the annual labor required by statute.

MOLYBDENUM ores are difficult to concentrate when associated with chalcopyrite, as these minerals have nearly the same specific gravity, while the presence of more than a trace of copper in molybdenum renders it useless for most purposes.

SHAREHOLDERS who have paid the taxes upon a patented claim owned by a defunct company would have a claim against the company for the sums thus paid, but unless legal steps had been taken to dissolve the company and to vest title in the individual shareholders they would not hold a possessory title.

THE ONLY gas produced from crude oil up to within a very recent period, has been one having a value from 550 to 680 B.t.u. per cubic foot, used for domestic lighting and cooking. This gas has been produced by the process known as the 'cracking' of the crude oils, which is largely disruptive in effect and frees a very large percentage of hydrogen and carbon, resulting in a gas carrying 50% and upward of free hydrogen. This gas will give no higher efficiency in a gas engine than distillate.

ASBESTOS is classified as amphibole and chrysotile. The amphibole, or hornblende asbestos, does not have the fineness of fibre, the tensile strength, the elasticity, or the flexibility of the chrysotile, although it has approximately the same heat-resisting qualities. The amphibole differs from the chrysotile chemically, in having lime combined with its magnesia, and while the chrysotile, a silicate of magnesia, is always hydrated, the amphibole is frequently anhydrous. Chrysotile is best adapted to commercial uses.

DESIGN of an elevator for performing any special service and the selection of the proper buckets or cups are problems that should usually be referred to an engineer familiar with the operation of such machinery. So many details enter into the design of an elevator that general rules covering all cases cannot be given. The shape and size of the buckets, their spacing on the belt, their speed, the size of the pulleys, the inclination of the elevator, and the manner of loading the buckets bear directly on the operation, and all these points must bear a definite relation to each other.

BLACK SANDS can be concentrated like any other mineral, and from their high specific gravity are comparatively easy to concentrate. It is somewhat difficult to separate the gold from the other heavy minerals in black sand, but it can be successfully accomplished by any one of several methods, mercury being the most convenient. The recovery of platinum is more difficult, as it will not amalgamate. But the importance of the occurrence of platinum in black sand has been greatly exaggerated, and many processes are chiefly aimed at the securing of a supposed metallic content which has no existence in fact.

FOR handling ore, stone, coal, and all heavy materials, elevators should be run at a speed of 200 ft. per minute or less, and the buckets should be spaced continuously on the belt or chain. In discharging from these elevators the speed is not sufficient to throw the material to the chute by centrifugal force, but gravity acts practically alone. In this way the material from one bucket slides to the chute over the back of its leading bucket. In order to insure a clean discharge, the backs of the buckets are usually provided with flanged sides, each one forming a trough for the material from the succeeding bucket.

IF THE DIP of a fault is greater than 45° it probably has a downward component, often combined with a horizontal component (normal fault). If less than 30°, an upward movement is common (thrust fault). If there is a gouge or slickenside or movement striae, the direction may often be told by use of a magnifying glass. Sometimes the feel of a slickenside (smoothness being developed in the direction of the grinding) shows the direction of the movement. Of course if the geologic column is known or if there are surface outcrops of the veins, methods of descriptive geometry will often exactly solve the problem.

IN MAKING a mineral location upon public domain, it is usually not necessary to know upon what section of land it is, or to tie the location to a land survey monument, possibly excepting placers; but with agricultural and other entries and patents rapidly encroaching on mineral lands, it is often necessary in trying to keep clear of them, or in the case of disputes, to be able to find tracts of land in the field by their markings. In case of a contest between mineral and agricultural claimants each legal subdivision of 40 acres constitutes a unit. The Government prefers that placer claims conform to legal subdivisions whenever practicable, in such cases permitting the claims to be entered for patent without further survey or plat.

COBALT is principally used in the United States in making glass and pottery. A beautiful blue is given to glass by the oxide of cobalt. Sympathetic inks, according to a report of the United States Geological Survey, are made from cobalt acetate, chloride, and nitrate that are colored when heated and colorless when cold. This interesting phenomenon is due to the change in color of the salts on the absorption of water. When dry they are blue and easily seen on paper; when damp they are pink; and when dilute, colorless. A puzzling application of this principle may be in a doll whose dress is blue in dry weather, but changes to pink when subjected to dampness, as in wet weather or when the doll is held in the steam of a tea-kettle. Artificial flowers are made to show the same effect.

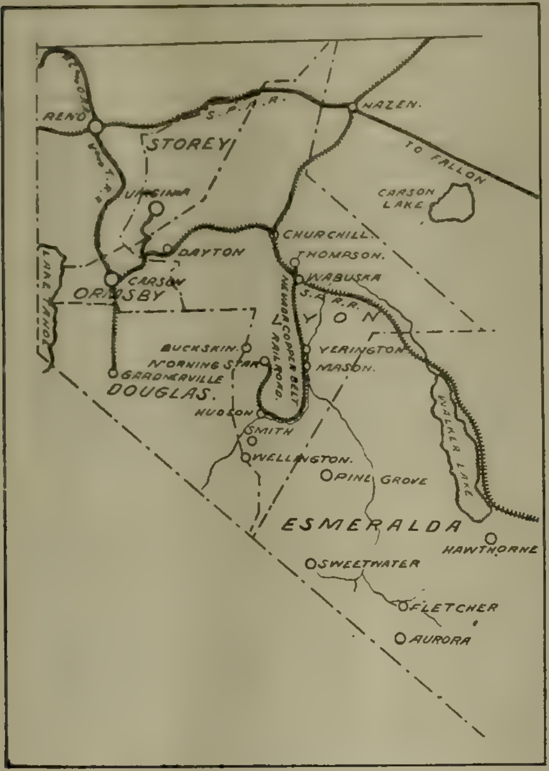
SAMPLING of a large stationary tank or reservoir of oil, particularly if the oil has stood so long that it has begun to stratify, or form layers of different density, may be done as follows: The sampler should procure an ordinary iron pipe, or preferably a tinned tube, 1 in. diam. and long enough to reach from above the man-hole, where he can grasp it, to the bottom of the tank. The lower end of the pipe should be reamed out with a round file. A conical plug of cork, wood, or other suitable material should be fitted to this end, and a strong, stiff wire, such as the ordinary telegraph wire, run through this plug and up through the pipe to a point where it can be grasped firmly by the sampler. A pull on the wire will close the bottom of the pipe, and a rap against the bottom of the tank will drive the plug home and make an oil-tight seal or valve.

Special Correspondence

NEW YORK

Stocks Dull.—Yerington Reorganization.—Braden Mill to Be Doubled in Size.—Copper Situation Weak.—La Rose Con. Postpones Surplus Distribution.

In a market way there has been little of interest during the week. Copper metal has been weak rather than otherwise, and the ruling price has been not above 12½c. The stock market has turned dull and is without any feature of interest. The Yerington Copper Co. is to be reorganized into the New Yerington Copper Co. The holders are to give up two shares of old stock for one in the new company. The Yerington properties are near the Mason Valley, and the new company will probably be managed by Duncan MacVichie. Braden Copper is apparently to be one of the low-cost producers whose output must be considered in making any figures on the copper situation. The Guggenheim engineers are figuring on between 6½ and 7½c. for copper with an output of 40,000,000 lb. per year. The 3000-ton mill probably will be doubled. The plant includes a hydro-electric equipment from which power is carried some 18 miles to run the concentrator. The directors of the Tennessee Copper Co., who, under the guidance of Herman Keller, recently made a trip of inspection to Ducktown, Tenn., report themselves as much pleased with the work which has been done in bringing the company's plant up to its present efficiency. The party included, besides Mr. Keller, H. M. Kilbourn, one of the vice-presidents of the National City Bank of New York, Joseph Walker, Jr., and Richard Sutro of Sutro Bros. & Company.



MAP OF SOUTHWESTERN NEVADA.

The copper situation is admittedly somewhat complicated and delicate. Any further heavy decline in the metal would bring a large number of well known producers face to face with a loss on every pound of output, and the alternative of operating at a loss or suspending production. A considerable increase in the accumulated surplus, possibly 20,000,000 lb., is expected. The Hancock Consolidated, the Cole-Ryan property in Michigan, is to sell its copper through the United Metals Selling Co. The Hancock is now producing about 100,000 lb. per month. Lake Copper, at one time the pyrotechnic sensation of the Boston copper share market, is just getting to the point of making its initial shipments. The company is expected to ship 1000 tons of ore daily within a short time, to the Trimountain mill. The stockholders in the La Rose Consolidated Mines Co. were hoping for something in the way of a melon, but were disappointed by the action of the directors at the special meeting held this week. Notwithstanding the protest of some directors who insisted that the stockholders were entitled to an immediate distribution of a large part of the $1,500,000 surplus in the company's treasury, it was decided not to disturb any part of it until after December 31, which is the end of the company's fiscal year. At the annual meeting the matter is to be taken up.

The smelting industry, upon which the larger business of mining must chiefly lean, is a field peculiar to itself, in that it is occupied by probably the fewest and the biggest middlemen in the world. The smelting of copper ores to the extent of a billion pounds or more annually in the United States is carried on at eight plants, of which three are owned by the Guggenheims, and two by the International Smelting & Refining Co. Next in rank to the plants mentioned is the Laurel Hill refinery of the Nichols Copper Co. which handles the ores of the Phelps-Dodge company. The Balbach refinery is operated by the American Metal Co., which latter is primarily a metal broker. By custom in this country the smelting of copper and the selling of the metal have always been handled by the same concerns in greater part. And it is a typical illustration of the modern tendency of concentration that so gigantic an industry should be so completely controlled by concerns that can be numbered almost on the fingers of one hand.

The decline in lead prices is affecting many of the lead mines. The present price for the metal is around $4.10 to $4.25 per 100 lb., with indications of lower prices in the near future.

BLUEFIELDS, NICARAGUA

Record Run at La Luz Mine.—Power-house at Patunka Falls is Planned.—New Mining Laws of Republic.

The September run of the La Luz & Los Angeles mine, which amounted to 1646 oz. of gold, made a new record for the mine. As the La Luz bullion assays over $17 per ounce, the total value of the production is about $28,000. The La Luz is worked by open-cut, but a vein has been found at a depth of about 120 ft. which assays on the average $125 per ton, according to recent reports.

Work will be started in the near future on the proposed power-plant at Patunka falls on Labue river, about one mile above Cuicuina. At present steam is used. H. J. and J. R. Amplett are in charge of the mine.

The recent changes in the mining code have aroused great interest among mining men. The decree is as follows, as published in *The American* of Bluefields:

"The President of the Republic,

Considering,

That until a total reform of the laws regulating the Mining Industry is brought about and in accordance with the progress attained by the same, deems it convenient to make various reforms in the Code treating of the matter, and to dictate dispositions which tend to the better development of enterprises already established, and using the legislative faculties with which he is invested,

DECREES:

The following reforms to the Mining Code of the 19th of February of 1906.

Art. 1.—The Article 62 will read as follows:

Ninety days after the registering is ratified, any qualified person may solicit a claim adjoining those of the discoverer, in the direction of the vein or ledge, and it can only be done in the direction of the dip or pitch of those whose formation lies horizontally in strata in such a manner that they do not present a proper continuation following a determined direction.

These solicitudes will be entered in the register and will be published in the same manner as that of the discoverer.

If the solicitude refers to a distinct ledge situated on the side of the pitch of another already conceded and less than three hundred metres from the limits of said claims, the publication of it will not be sufficient, but the solicitude will be notified in conformity with Art. 65 of the Code, being subject to nullity in favor of the owner of the known ledge; who will have the preference in the adjudication of the new solicitude, if he makes his right valid within thirty days, plus the interval of time necessary to cover the distance, to begin from the moment of notification.

Art. 2. Art. 212 is derogated. This derogation and the following reform of Art. 214 does not affect pending denouncements and concessions, the procedure of which will continue and be governed in conformity with the dispositions of the Code and its reforms.

Art. 3. Article 214 will read: at the expense of the interested parties will be published three separate times within the term of one month in any newspaper of the capital the solicitude made to the Executive Power to acquire the sites and plants referred to in Article 213; the solicitude to be communicated to the District Judge in whose jurisdiction said properties are situated.

Priority of petition made to the Executive or the Judge will establish the preference in the adjudication, excepting that which is ordered by Art. 217.

Art. 4.—Article 218 is derogated.

Art. 5.—Article 222 will read as follows: failure of payment of the right in conformity with Art. 204 of the law, will immediately cause the forfeiture of any zone concession without recourse, the concessionaire having the right to retain only the mining properties which he may have legally established.

Art. 6.—Article 223 will read: the concessionaires of zones are obliged to establish at least one mining property within the first year of their concession; not fulfilling which they will pay as an annual contribution one peso for each hectare contained in said zones.

If, after five years from the granting of the concession the legal obligations to develop the zone on a large scale are not fulfilled, the concession will terminate, the rights acquired in it will be lost, except that of the concessionaire retaining the mining properties which he may have legally established.

Art. 7. Article 224 will read: Failure to measure the zone during the time allowed for same will cause forfeiture of the concession. Time allowance may be extended only once, and for a period not exceeding the first.

If for a period of six months the interested party fails to demand the furtherance of his solicitude of a zone or extension of time, this will occasion the caducity of the denouncement.

Art. 8. The following paragraph will be added to the second part of Art. 231: likewise coal, naphtha, gasoline, crude petroleum, and any other similar combustible; tanks and vessels for the transportation and preservation of the same; all classes of utensils necessary for the process of cyaniding, such as cyanides, tanks, iron or wooden boxes for precipitating, zinc in sheet or chips; lathes to make these, pipes, ovens, and other articles and substances used in the aforesaid system.

Art. 9. Article 230 will read: The renewal of matriculations will be made each year and the Jefe Politicos will remit a copy of them to the Ministry of Hacienda with the object mentioned in the following.

Art. 10. It is prohibited to make clearings and sowings or establish whatever other agricultural or cattle breeding enterprises on the lands near to mines that are being worked, or near springs or fountains and on the banks of rivers and streams whose waters are utilized in mining establishments; and miners will only be permitted to establish yards or small gardens and pastures for the penning of their animals or other usages necessary to their undertaking.

Lands within a radius of fifteen hundred metres will be considered as close to a mine.

Any contravention to the requirements of this article will be punished executively by the mining authorities with a fine of from 100 to 500 pesos, such to be destined for the repair of the roads of that district.

Art. 11. The present law will begin to be in force from its publication and derogates all measures opposing it.

Given in Managua on the 26th day of the month of September of 1911.

Adolfo Diaz.
The Minister of Fomento,
A. Canton."

JOPLIN, MISSOURI

Smelter Strikes Settled, and American Zinc, Lead & Smelting Co. Re-enters the Market.—Method of Mine Ventilation.—Penetrate Underground Lake.

Labor difficulties at the smelters of the American Zinc, Lead & Smelting Co. at Deering and Caney, Kan., have been adjusted satisfactorily, and this company is again purchasing zinc sulphide ores in the Missouri-Kansas-Oklahoma district. The contract system is again in force, making it possible for the ore producer to dispose of his output at a figure weak or strong, according to the price of spelter, East St. Louis quotations. At the close of October, when the price was about $6.25, sulphides, sold in the open market, commanded from $38 to $45 per ton, on an assay basis of 60% metallic zinc, while ores sold on contract ranged from $46 to $49 per ton, assay basis, choicer lots bringing as high as $52. The American company is opening new mines in the Joplin district and materially increasing the source of its own ore supply. The weekly shipments from the American mines at Prosperity are now about 300 tons of blende; from the Duenweg mines, about 100 tons, and from other mines of the district, about 100 tons. The company also is planning to develop a large tract west of Joplin on which recent drill prospecting and new shafts have revealed rich deposits of high-grade blende. The output of the district is gradually increasing, being now about 4800 tons per week, and this figure represents a fair average for the year. The weekly average for other years since 1902 are as follows: 1902, 5048 tons; 1903, 4516 tons; 1904, 5139 tons; 1905, 4854 tons; 1906, 5364 tons; 1907, 5511 tons; 1908, 4988 tons; 1909, 5792 tons; and 1910, 5322 tons.

Cases involving the sale and transfer of Indian lands near the zinc and lead mining districts of Quapaw and Miami, Oklahoma, which were argued recently before the United States circuit court at St. Paul, Minnesota, have been passed upon, the verdict being a victory for the Government. The decision holds that the Indians have no right to sell their lands personally, nor can their heirs dispose of them, unless the transaction is through the Department of the Interior. This means a saving to the Indians of lands valued at $1,000,000.

Ore assaying barely 1% zincblende is to be mined by the Moler-Smith Lead & Zinc Co., of Carl Junction, Missouri, a company which already is milling 1½% ore at a good operating profit.

Ellisville, a new mining camp that has every indication of developing into a heavy producer, is springing up rapidly as the result of operations conducted in the bottom of an old shaft put down by Watkins and associates on the Connor Realty Co.'s land, two miles due west of Joplin, eight years ago. The shaft went to a depth of 85 ft. through solid limestone and was abandoned. B. P. Ellis last spring, at a depth of 88 ft., found zincblende which assays about 15%. It continued to a depth of 104 ft. Other drill-holes were sunk and the formation blocked out. A number of shafts are now being sunk and half a dozen drill rigs are busy on this and adjoining lands.

DENVER, COLORADO

Apex Law Causes Much Litigation.—Golden Cycle Dividend.—Clancy Process to be Tried in New Colburn Mill.—Nevada Bullion at Denver Mint.

The theory of extralateral rights has engendered much bitter mining litigation in Colorado of late. Three suits at law, involving some of the largest companies in Colorado, are now pending adjudication in the Federal courts. On October 19 the Vindicator Con. Gold Mining Co. brought suit in the Federal court at Denver against the Golden Cycle Mining & Milling Co., to recover $2,733,182 damages for ore which the former company claims was unlawfully extracted from its property by the latter. According to the allegations, the ore in question was taken out of a vein of which the apex is on the Christmas property of the Vindicator company, but which dips across the sidelines into the territory of the Golden Cycle company. The Vindicator company has retained the firm of Thomas, Bryant, Malburn & Nye to press its claims for damages in the Federal courts. The Golden Cycle has also employed counsel, and while the officers of the company persistently refuse to give out any intimations of their plans, it is known that they are preparing to enter a strong denial of the charges and contest the suit vigorously. The case is said to present difficult angles which will require the assistance of expert geologists and engineers to untangle. Each side is preparing for the introduction of much expert testimony.

LIBERTY BELL MILL.

Coincident with the announcement of the filing of the suit comes notice that the Golden Cycle company, on October 25, declared a special dividend of $1,500,000, and checks for the same were immediately sent to the stockholders, the principal of whom are John T. Milliken of St. Louis, Frank G. Logan of Chicago, H. McGarry of Colorado Springs, and A. E. Carlton of Cripple Creek. The Golden Cycle has been paying for some time regular dividends amounting to $30,000. Besides its mining properties on Bull hill, the company operates a custom milling plant at Colorado City and a smaller one at Cripple Creek. The Vindicator and Golden Cycle companies have each paid about two and a half million dollars in profits.

The Liberty Bell and Smuggler-Union companies, near Telluride, are involved in apex litigation which is still being pressed in the district courts. A third case now pending is that of the Neglected and May Day mines in the La Plata mountains near Durango, where the litigation has caused a suspension of operations in both properties for the present.

The Ajax Mining Co. has announced that the new Colburn mill, employing the Clancy cyanide method, will be started up shortly after November 1. The crushing department will handle 300 tons and the chemical department 200 tons per day of 24 hr. The mill will handle both high and low-grade ores, and besides treating the entire mine product, will treat some 200,000 tons of dump ore, the value of which will average about $4 per ton. The metallurgical details in the application of the process were under the supervision of A. W. Warwick, consulting engineer for the Ajax company and for the Moore Filter Co. of New York, owners of the Clancy patents.

The Grubstake Committee of the Denver Chamber of Commerce, which put in operation last spring a plan to revive the State's mining industries by sending out prospecting parties to search for new ore deposits, to be supported by popular subscription, is calling in the men who have been in the field during the summer. The season is closing and the committee now desires to take an inventory of the work done and the locations made. Max Boehmer, chairman of the committee, says its work has been successful. A final report of the committee will be made about November 15. It is announced by officials of the Chamber of Commerce that the plans for the formation of a big development company to exploit the more desirable locations taken up by the Grubstake Committee will be completed. To raise the necessary funds, stock in the development company is to be offered to the business men of the State.

The Denver Mint is receiving shipments of gold bullion from the Goldfield Con. Mines Co., and from other gold mines in Nevada. Federal officials state that Denver will become a general depository for gold bullion, it being considered more advisable to store it here than in seacoast towns. It is reported that $500,000,000 in gold now rests in the vaults of the Denver Mint.

KALGOORLIE, WESTERN AUSTRALIA

Geological Department Investigating Mining Districts. -Flotation Process to Be Tried at the Lancefield.—Mundaring Reservoir Overflows.—August Statistics.

The month has been characterized by an almost entire absence of any developments of note, or other matter in connection with the mining industry. The Government Geological Department has been busy examining the country between Norseman and Esperance for water supply. Interest is shown in the coal measures at Donnybrook in the southwestern part of the State, and the country between Sandstone and Lawlers in the East Murchison. Inspection is proceeding also at Mount Ida, north of Menzies and in the north end of the Kalgoorlie field, Coolgardie and Burbanks. These general examinations should be of value to the community, and the Chamber of Mines has asked the Department to issue reports as early as possible.

In the Yuanmi mine, belonging to the Oroya Exploration Co. the 300-ft. level continues to show well. The north drift from 181 to 198 ft. is in ore assaying $8 per ton, the vein being 52 in. wide. From 198 to 207 ft. the ore assays $14, and the vein is over 59 in. wide. The 20-stamp mill and the cyanide plant are well under way. The north drift at the seventh level in the Lancefield shows ore assaying $9.20 for 99 in., and the south drift $4.50 for 60 in. Experiments are being tried with the Minerals Separation flotation process, so successful at Broken Hill. The Golden Ridge, a locally controlled mine, fourteen miles from Kalgoorlie, in consequence of the bottom, the 500-ft., level showing poor ore, has decided to cut its monthly profit from $14,000 to $8500.

The Mundaring reservoir, the source of the water supply, is overflowing again, so there is 4,680,000,000 gal. available. The State Premier, in a recent speech, gave the preliminary figures for the past financial year for the plant as follows:

Gross income	$1,185,000
Expenses	354,000
Surplus	$831,000
Interest	561,000
Sinking fund	270,000
	$831,000

The surplus failed to pay all the sinking fund by $125,000, against $260,000 in the previous year, and $500,000 in 1904, so the situation is improving, and in 1912 there should be a balance on the right side. The benefits to the mining and agricultural districts near the main are important. The main conduit and extensions now total 875 miles.

The August gold yield from the State was valued at $2,420,000, and dividends were paid amounting to $38,500. The following goldfields contributed to the total:

East Coolgardie (Kalgoorlie) from 148,000 tons	$1,408,770
Mount Margaret	242,310
Murchison	195,570
East Murchison	144,570
Norseman	131,140
North Coolgardie	105,140
Coolgardie	58,690
Southern Cross	29,900
Kanowna	27,870

The Commission on Miners' Phthisis has been taking evidence during the past fortnight from doctors, mine managers, miners, and municipal officials. It is to be hoped that some sound conclusions will be drawn from the evidence; but it is certain that there will be a lot of the same ground covered as by the commissions on the same subject in Bendigo, the Rand, and Queensland.

The returns from the principal producers during the month of August were as follows:

Name.	Tonnage.	Value.	Profit.	Cost per ton Mining.	Cost per ton Treatment.	Cost per ton General.
Associated	10,692	$69,000	$10	$2.00	$2.64	[3]....

In these costs development and plant extensions are not included.

SALT LAKE CITY, UTAH

WEAKNESS OF LEAD MARKET THREATENS TO CLOSE MINES.—INDEPENDENT DEVELOPMENT PLANNED FOR THE DALY.—SILVER KING COALITION INCREASES OUTPUT.

Something of a scare has been thrown into the lead producers of Utah by the weakness of the lead market, and much speculation is going on as to what will happen if the price drops much farther. Utah is second among the States in lead production, and with a good market the output for 1911 would probably exceed that of 1910 by 25%. The 1910 production was 123,324,635 lb., valued at $5,549,588. The Utah producer has been favored by fortune this year in having three large smelters competing for the output. The American Smelting & Refining Co. and the United States S. R. & M. Co. fought hard for contracts some years ago, but in recent years they have not competed with each other so keenly, and they were going along peacefully until the International Smelting Co. announced that it would put in lead stacks and began bidding for ores. Then the older companies got busy, and the owners of lead mines have had a period of prosperity. In the competition for tonnage, exceptionally low rates have been made on low-grade lead ores, with the result that some of the older mines have begun shipping from their dumps, as well as sending out second-class ore left in the mines as unprofitable to ship. Fear is now being expressed that the increase in the Utah product, coupled with the slackness in consumption, are in themselves sufficient to account for the weak market. The local miners have been settling right along on the basis of $4.50, less the usual deductions for freight and similar charges, even when the New York quotations were down as low as $4.35. This cannot continue indefinitely if the market continues to sag. If lead goes to $4, it may not close many mines, especially if silver is strong, but a drop much below that figure will send a number of mines out of commission until conditions improve.

The merger of Park City properties has been abandoned, at least for the present. As a result, independent development work will be pushed on the Daly. There is much promising territory in this old property, which has shipped silver-lead ores amounting to $9,579,229 and paid $2,925,000 in dividends. Vigorous development of the virgin ground, it is believed by many mining men, will result in the opening of a new mine. Whether E. A. Wall will be inclined later to favor merging with any other property is a question. It is known that he has been a heavy stockholder in the Silver King coalition company, and a future merger might lean in that direction, although combination with the Ontario and Daly West has long been regarded as the first step in a large Park City merger.

The Silver King Coalition, having completed placing its underground electric equipment, is now sending out the largest tonnage in the history of the company. The Daly-Judge also is shipping heavily, while the Daly West is coming up strongly, all of these properties having silver-lead ore as the bulk of the product. The three companies have joined in purchasing 700 acres of land, at a nominal price, on which they will impound tailing from the various mills. This is being done to avoid lawsuits with farmers for permitting tailing to lodge on their ground.

In a letter to the stockholders, Urban H. Broughton, the retiring president of Utah Consolidated, says that the development work of the year has resulted in the uncovering of a tonnage equal to the amount mined, but that copper, gold, and silver contents are lower. Prospecting in the western part of the ground has uncovered two lead orebodies. There is now developed 23,000 tons of 17% lead ore, and 15,000 tons of 7% concentrating ore. The profit for the year is given at $300,000, and a $150,000 dividend was declared. It is stated that a large part of the profit came from selling the metal secured in dismantling the old smelter.

From Little Cottonwood comes an interesting shipment out of the recently organized Alta Consolidated. This company sent out about 33 tons of ore on which the control assays were 0.015 oz. of gold, 101.3 oz. of silver, 13.1% lead, 6.3% copper, 10% zinc, 21% silica, and 10% iron. Another similar shipment of 40 tons followed the first.

General Mining News

ALASKA

Juneau

The report of the Alaska Mexican G. M. Co. for the month ended August 15 shows a net profit of $26,169. The report was delayed, as the original copy was lost on the wrecked steamer *Ramona*.

The Alaska Treadwell G. M. Co., in the 15 days ended September 30, milled 38,640 tons of ore, from which 756 tons of concentrate was saved. The total production is valued at $91,426, with a realizable value of $90,246. The estimated net profit for the period was $41,489. The yield per ton was $2.36. Development work done in the period amounted to 408 ft. The stock of broken ore was increased 1529 tons.

MAP OF ALASKA.

Kodiak Island

Near Uyak exceptionally rich placer deposits have been found recently, according to reports from Cordova, and it is believed that the district may become important for its placer mining.

Prince William Sound

The customs mill erected by subscription at Valdez is now in operation.

A $5,000,000 company is to be organized to develop the Cameron-Johnson property, the title to which has been cleared in the courts. The claims are said to be among the richest in the Shoup bay district.

M. M. Reese, president of the Ibex and Mayfield companies, is quoted in the press as stating that in the spring a mill may be built on the Mayfield property.

At the annual meetings of the Mineral Creek M. Co. and the Chugach M. Co., at Valdez recently, the consolidation of the two companies was ratified.

Seward Peninsula

Reports from Nome state that the York Dredging Co., in less than a month of actual operation, has produced 70 tons of tin concentrate from the placer deposits along the Buck, Grouse, and other streams around York.

ARIZONA

Cochise County

Rich ore has been discovered on the Leadville property, near Paradise. G. A. Walker owns the mine.

Gila County

(Special Correspondence.)—The Copper Reef mine, 12 miles south of San Carlos, is employing 20 men. The inclined shaft is being sunk and is reported to be about 700 ft. deep. It is proposed to develop two veins from this shaft, and cross-cutting is in progress on the 6th level both north and south from the shaft. No ore is reported yet on this level. The property consists of 80 claims and is traversed for a distance of 4000 ft. by five veins with prominent outcrops showing considerable copper in the form of carbonates. John W. Gillingham, of Los Angeles, is general manager, and Charles T. Martin, of Globe, is managing director. The results of the recent directors' meeting have not been announced.

The McGaw shaft of the Superior & Boston is now below the 12th level. A sump is being cut preliminary to placing a station on that level. This is the only development work going on at present. Assessment work is being done on the unpatented claims. About 50 men are employed.

The Arizona Commercial is still idle pending reorganization of the company. The mine is being kept free of water and the railroad to Globe is in operation.

Globe, October 27.

Yuma County

It is rumored that the Clara Con. M. Co.'s property and smelter have been purchased by the Con. Arizona Smelting Co. of Humboldt. W. A. Clark is believed to have the controlling interest in the Con. Arizona company.

CALIFORNIA

Amador County

About 30 men have been laid off at the Central Eureka mine, says a newspaper report from Sutter Creek, and attention will be given to prospecting the lower levels of the mine. The mill has been treating ore from several levels, but there were indications that the ore-supply would soon be exhausted. It is thought that a vein can be tapped on the 2700-ft. level. An assessment of 4c. per share is being considered.

Owing to the expense of purchasing the Oneida property, the South Eureka M. Co. has omitted its regular monthly dividend of 7c. per share, state recent newspaper reports. The mine and mill are making their regular production, it is stated, but the payments on the Oneida, which is said to have been priced at $150,000, necessitate the suspension of dividends.

After being shut down for more than 20 years, the Empire and Pacific mines at Plymouth are being unwatered for development.

Calaveras County

Press despatches from Mokelumne Hill state that John Garavanti has sold the Garavanti quartz mine to British investors for $15,000.

Inyo County

The total production of the Skidoo M. Co. for the month of September was $19,097. The development and operating expenses amounted to $9059, leaving a net profit of $10,038.

Mono County

A prospecting tragedy was revealed last Saturday when the body of J. J. D. Miller, of Virginia, was found in a prospect hole 12 miles north of Bridgeport. The miner had been pinioned by a leg in a fall of rock. An improvised diary written on the back of an assay certificate showed the accident occurred October 6. The last entry, "No hope," was made on Friday, October 13. Miller is survived by his mother and his widow.

Nevada County

At the Holbrooke mine, says a report from Grass Valley, the miners have tapped a tributary to the main ridge channel which runs through the Posey property. The shaft, which now is down 106 ft., will be sunk to bedrock and cross-cuts will be driven at that depth. The shaft is about 400 ft. downstream from the point where E. C. Webster, some years ago, took out much rich ore. The Holbrooke is operated by the Reber M. Co., for which H. Reber is superintendent. The company employs one shift of five men. Development is hindered by water, which fills to a depth of about 40 ft. during the night. A 6-in. Cornish pump is used to clear the shaft of water.

Placer County

C. T. Snedeker of Chicago has purchased the Reublin mine at Last Chance from D. M. Ray and F. G. Albnos, according to recent reports from Auburn. It is stated that Mr. Snedeker will build a mill and will buy other machinery for developing the mine.

Plumas County

During assessment work at the Bullion mine, near Clio, a decomposed quartz ore panning about $40 per ton was discovered. The men, after driving a cross-cut 13 ft., had not reached the foot-wall, state recent reports. R. J. Read is superintendent of the property, which is in the Mohawk valley.

San Bernardino County

The Greenwater Copper M. & S. Co. has secured an option on the Supply group of 17 claims and the O. K. group of 10 claims in the Dale district from H. A. Landwehr, president of the Seal of Gold M. Co. Mr. Landwehr obtained title to the claims after some bitter litigation with Riverside stockholders in the Seal of Gold company, which he had organized to develop the claims. It is rumored that the purchasing company is identified with the Guggenheim interests.

Tuolumne County

The Slap Jack mine, idle for a dozen years through litigation, again will be developed, state reports from Groveland. A power-line will be built, and power taken from the Gold Ship to operate the mine. An electric hoist will be bought and the old head-frame will be replaced. The construction of a mill is under consideration. Richard Pierce is superintendent of the mine.

The Stanislaus Mining and Development Co. has been organized to operate the Crystalline mine. The company, which is capitalized at $500,000, was incorporated by H. A. McQueen, A. J. Schmidt, and J. E. Hill, and has offices at Modesto.

Construction work for the tube-mill for the If-I-Can property on Stanislaus river will be started soon.

Extensive caving-in at the App mine threatened much property in the town of Quartz, situated above the mine, and caused alarm to the residents. J. A. Keys, foreman of the mine, asserted that the mine was not damaged. The caving was caused, it is said, through failure to fill up properly the abandoned stopes. The power-line supplying illuminating current for the town was broken down by the caving, which left a depression reported to be about 100 ft. deep, 200 ft. long, and 150 ft. wide. The mine is owned by W. A. Nevills of San Francisco.

Yuba County

(Special Correspondence.)—Rich quartz continues to be developed on the Twentieth Century Wonder claim, owned by J. Rose. The vein averages 2 to 3 ft. wide and has been developed for 15 ft. It is claimed that much of the ore thus far extracted ranges from $100 to $3000 per ton. The property is situated in the Dobbins district, near Rackerby. At the Red Ravine, the first property to attract attention to the district, good ore continues to be developed, with bonanza showing at several points. It is reported that Los Angeles people are negotiating for the Seaborg & Davis property; also the Spanish mine. These properties were worked in a small way years ago, and commercial ore is said to have been opened below the 150-ft. point. At the Manzanita the shaft is down 125 ft. with the vein showing a width of 3 ft., and some high-grade ore has been found. Eight men are employed. New machinery is arriving at the Santa Rosa, lying south of the Manzanita. The Abbot mine reports a 3-ft. vein of ore assaying from $8 to $15 per ton in free gold. The shaft is down 60 ft., and is being sunk farther. The main orebody of the district is said to be traceable for 15 miles, with an average surface width of 7 ft. It courses north and south, between belts of slate and porphyry. Several mining experts are in the district, examining prospects.

Marysville, October 29.

The Mark Anthony M. Co., with its principal place of business at Marysville, has been incorporated by W. H. Carlin, H. A. Niemeyer, Emma A. Coughlin, W. E. Langdon, and Maude Lunsford. The Mulberry M. Co. has been incorporated by C. E. Harmon of Oakland, and J. D. Jessup and James W. Scott of San Francisco. Its principal place of business is to be at San Francisco.

COLORADO

Boulder County

The Central Colorado Power Co. has offered to build a $150,000 custom stamp-mill at Boulder if the Boulder Metal Mining Association can show there is enough ore in the district to warrant the investment. The Association is now collecting specimens from all of the camps, and it is believed that the mill is practically assured.

Clear Creek County

(Special Correspondence.)—The Dorit property is to be equipped with an electric-power plant. F. L. Patrick is manager of the mine. The Lalla mine at Alice, owned by the King Solomon L. & E. Co., is to be equipped with a 50-ton concentrating mill, a contract for the machinery having been awarded to the Traylor Machinery Co. of Denver. F. Dinsmore is manager. The Emerson vein cut by the Lucania adit proved to be 238 ft. wide, all ground being heavily mineralized. L. Sternberger is manager. The Silver Creek property has been secured under bond and lease by S. A. Offerson and development has been started. Shipments have been started from the Pioneer mine that was recently secured under bond and lease by Denver parties. The New System mill is running steadily upon ore from the Mint mine. The sinking of the shaft is progressing satisfactorily.

GOLDEN CYCLE MINE.

Idaho Springs, October 29.

(Special Correspondence.)—Work is to be resumed on the Bellevue-Hudson mine, situated on Columbia mountain. The shaft from the 14th level is to be made two-compartment. Ore is showing on the 80-ft. level that mills 725 oz. silver and 3.50 oz. gold per ton. G. W. Boyce of Denver is manager. A new blacksmith shop and ore-house have just been constructed at the Little Giant mine on Red Elephant mountain. Shipments of 400 oz. silver ore are being made. E. Minier is manager. New rails and air-pipe have been purchased for the Alabama mine on Leavenworth mountain. James O'Donnell is manager. The Big Indian adit has been driven 178 ft., and from surveys it is thought a vein will be cut shortly. E. Butts is manager. Work is going forward at the Key West mine and driving is in progress on an 8-in. streak of silver-lead ore that is worth $45 per ton.

O. Johnson & Co., lessees of the Seven-Thirty mine, are stoping on an 8-in. streak of ore that mills 399 oz. silver per ton. Joseph Wood, leasing on the Bismarck, has started shipment of ore, and returns of 575 oz. silver per ton are being received in settlement. A body of ore 12 in. wide has been uncovered on the 300-ft. level of the Aetna vein at the Capital mine. It assays 12 oz. gold, 18 oz. silver, 42% lead, and 7% copper. E. Bauman is manager.

Georgetown, October 30, 1911.

Teller County (Cripple Creek)

The Golden Cycle M. Co. has paid a special dividend of 70c. per share on the entire issue of 1,500,000 shares, and has $750,000 still in its treasury for operating. The company will continue its regular dividend rate of 2c. per month. There are about 35 stockholders.

Work on the Roosevelt deep drainage tunnel has been stopped owing to trouble with the electric hoist at the Intermediate shaft, and several days will be required for repairs. The adit has been driven over 15,800 ft. There is a flow of about 6500 gal. of water per minute from the portal, according to T. R. Countryman, the engineer in charge of the work.

Emerson & Wilson, lessees on the Morning Star claim on Bull hill, have purchased a 6 by 8 hoist from J. H. Wilbur, and prospecting will be started at once.

Active development work has started on the Blue Jay claim on Bull hill, under the direction of R. P. Russell. It is stated that the Blue Jay and Blue Bird are about to settle their apex dispute in the courts.

IDAHO

BOISE COUNTY

William Schuerding, formerly of Butte, Mont., and associates of Wallace, have acquired control of the Sunset Banner group of five claims on the west side of Beaver creek, opposite the Tuscumbia and Idora properties, in which district also are the Nipsic, Amazon-Manhattan, Callahan, and the Clark claims. He has organized the Sunset Development Co., with a capital stock of $500,000.

IDAHO COUNTY

H. M. Collette and associates have leased the Jumbo mine, at Buffalo Hump, near Grangeville, and development work will be started at once. A cyanide plant costing $20,000 will be built. Previous to the signing of the lease, an investigation extending over several weeks was made by engineers.

SHOSHONE COUNTY

The new adit at the Stewart mine is in more than 1100 ft. and it is believed that the work can be completed during November, as only about 300 ft. of work remains to be done. The first electrically heated dry-room in the district has been built at the mouth of the lower adit. It is reported that the room is so successful that other mines will build similar dry-rooms.

Two shifts of men will be used throughout the winter at the Snowstorm Extension M. Co.'s property, according to a statement by B. H. Lively, manager for the company. Two veins of lead ore have been found.

MONTANA

LINCOLN COUNTY

(Special Correspondence.)—The work of reconstructing the buildings and reopening the mines at Sylvanite owned by the Lincoln G. M. Co., will not be resumed until next spring, according to J. H. Ehlers, who is interested in the company. The buildings were burned by a forest fire over a year ago. When work is resumed the company will use electric power generated at the Yakt falls where a power-plant is to be constructed at once by the Milwaukee Power Co., a separate organization. It is the intention to develop 3400 hp. at the falls. Lumber for the power company's buildings will be sawed at Sylvanite, where the mining company has a small saw-mill.

Libby, October 28.

The adit on the Kalispell-Lincoln G. M. Co.'s property in the West Fisher district is now in 90 ft., according to John J. Hibbard, manager of the mine. The orebody is about 2 ft. wide and assays about $100 per ton in gold. It is free milling and the company expects to build a stamp-mill within the next year.

MADISON COUNTY

(Special Correspondence.)—Madison county, famous for its gold mines, now promises to become famous for its tungsten. The discovery was made in a locality which was a great silver camp away back in 1874, and in that day the ore was mined and brought out on the back of pack-animals at a profit. An old prospector came across some ore in a dump which he decided to have examined, and it was discovered the rock contained hübnerite.

Virginia City, October 27.

SILVERBOW COUNTY

(Special Correspondence.)—The destruction of the concentrator plant of the Butte Reduction Works by fire on October 25 may result in hastening the erection of the proposed zinc smelter by W. A. Clark. The reduction works, built many years ago by Mr. Clark, was sold by him to the Anaconda Copper Mining Co. about a year and a half ago, but in order that he might have a place to treat the zinc ore from his Elm Orlu mine he was given a lease on the concentrator. He equipped the mill with modern machinery and it was supposed that when the lease expired in June next, he would get an extension of time sufficient to allow him to complete a plant of his own. Mr. Clark for the past few years has been giving a good deal of his time to the development of his zinc property, and, after selling out his copper properties to the Anaconda company, stated that he proposed to make the zinc industry a feature in Montana's industrial life. He has an option on a large tract of land in what is known as German gulch, a few miles from this city and within half a mile of both the Northern Pacific and Butte, Anaconda & Pacific railroad tracks, and on this ground the contemplated smelter probably will be erected. It is known that when he went abroad the past summer, 100 tons of zinc ore from his Elm Orlu mine was shipped to Germany for experimental purposes and that he personally watched the testing of this ore. The results of the tests were not officially made known when he left the German mill, but it is stated that since his return the figures have been received and show that the process was a success.

The Combination mine property has been sold at sheriff's sale to satisfy a judgment of $25,083.45 held against it by John P. Reins. Mr. Reins says that he does not intend to operate the property at present. The railway spur built for the Tuolumne company by the Butte, Anaconda & Pacific Railway Co. to haul the ore direct to the Washoe smelter is now in operation. It is believed that the new surface plant will be in commission by the middle of November.

A. B. Wolvin, president of the Butte & Superior company, and George Bradley, chief engineer of the Guggenheim interests in Utah, came to the city several days ago with some of the directors of the company and made arrangements for the commencement of the proposed new concentrator. The mill is to be erected near the Black Rock mine of the company and will have a capacity of 500 tons per day and will be so constructed that the capacity can be increased to 1000 tons by an addition at any time.

Butte, October 31.

(Special Correspondence.)—The Butte-Alex Scott is shipping 80 tons per day to the smelter and getting returns which pay all operating expenses and leave something to the good. The Little Annie, which is operated by the same company, continues to produce rich ore on the 200-ft. level, and its shipments of 50 tons of ore per week are coming from that level.

The construction of the new surface plant of the Tuolumne mine is going ahead with as much rapidity as possible, but the work at the best is slow, and it is not believed that the plant will be in commission before the first of the year. The sinking of the shaft to the 1800-ft. level has been completed and a station is being cut at that point. The shaft will be sunk to a depth of 2000 feet.

Butte, October 28.

NEVADA

CHURCHILL COUNTY

The Rex company, on its property north of the Nevada Wonder, has rediscovered the vein lost some time ago when a fault stopped development. The company, to hold its claims, had to do a certain amount of development work this year, and it was during this activity that the vein was again found. No assays have been made.

ESMERALDA COUNTY

A small vein of ore assaying $80 per ton has been found at the Vernal mine.

Ore assaying $300 per ton, according to press reports, is being sacked on two levels of the C. O. D. mine. L. K. Koontz is quoted as stating that the supply of high-grade ore justifies the erection of a mill, and it is thought the company later on will undertake the construction of one.

The production of the Goldfield Con. M. Co. for the month of September was 26,760 tons of ore, valued at $676,383, according to the official report issued a few days ago. The net average recovery was $23.80 per ton. The net profit was $16.60 per ton. Of the production, 81 tons had an average value of $77.12, and 26,679 tons was milled with an average extraction of 94.11%. The development work done during the month amounted to 3192 ft. The low tonnage was due to shut-downs during the re-lining of the tube-mills and repairing the Chilean mills. The ore from the working faces in the Mohawk dropped in value, and the production was accordingly low, but it is believed the October production is above the average. The foundations for the roasting plant and building practically have been completed, and construction work is being advanced in a satisfactory way. The Goldfield Con. M. Co., on October 31, paid a dividend of 30c. per share.

Eureka County

Elmer Isaac and Charles Vallenaueth, lessees of the patented claims of Maurice Isaac and W. R. Lewis in Mill canyon, about four miles north of Cortez, have 80 tons of ore ready for shipment, the ore assaying, according to report, from $32 to $165 per ton.

Humboldt County

(Special Correspondence.)—The Neshobe group, Barret Springs district, has been purchased by the New York men. The property comprises four promising claims. The vein is said to have gold and silver ore assaying $30 per ton. The new owners announce that development will be started within a short time. Frank Krenkel, of New York, represents the purchasers. The Major-Gomes silver-lead property has been taken under lease and bond by G. W. Warmoth, formerly of Valdez, Alaska. The mine is in the Adelaide district, 12 miles south of Golconda and 22 miles east of Winnemucca. The Arizona mine and mill at Unionville has resumed operations. The Imlay M. Co. reports the discovery of a 4-ft. vein of rich ore in a 15-ft. winze sunk from the 200-ft. level. Samples are said to assay $25 per ton in gold and 80 oz. in silver. D. E. Craft is superintendent. The Salt Lake & Winnemucca Leasing Co. is preparing to conduct developments along the lines projected by Duncan MacVichie. The company recently acquired six claims adjoining the famous Adamson-Turner gold property. Rochester canyon is entirely staked out by placer miners. Several rich surface discoveries have been reported, and owners are preparing for a busy season.

Winnemucca, October 28.

The capitalization of the Crawford Leasing Co. of National has been increased from $20,000 to $50,000. The par value of the shares is $1. The company owns, in addition to the Crawford lease, the Koekler lease, adjoining the former, and is planning to acquire other claims.

Lyon County

The Nevada Copper Belt railroad has been completed into the Mason Valley mining district. The last spike was driven last week. The Nevada Douglas Copper Co. expects to commence shipping gypsum immediately, state the reports, and the Mason Valley smelter should be ready for receiving ore by the middle of this month.

Mineral County

Newspaper despatches state that there is good authority for a report that Tonopah M. Co. has made a first payment of $50,000 on the Aurora group of claims, covering about 400 acres of ground. The mines were developed until 1884, when the cost of pumping the water from the lower levels stopped mining. Today steam has been replaced by electric power, of which there is an abundance, supplied by the power lines running through Aurora to Wonder. It is said there is enough low-grade ore which can be mined for $2 per ton, to keep a 100-stamp mill busy for many years.

Nye County

The report of the Tonopah M. Co. for the week ended October 21 shows that 98 of the 100 stamps were in constant operation. The ore milled amounted to 3300 tons, which yielded an average of $20 per ton. No concentrate was shipped, but 38 bars of bullion, valued at $53,000, were shipped.

An important discovery of ore has been made in the North Star mine. No assays have yet been made.

Work on the Tonopah-Belmont mill is being rushed, and the concrete work is about completed.

The Montana-Tonopah mill last week treated 1053 tons of ore, with an extraction of 89.2%. The concrete work for the MacNamara mill has been completed.

The total shipments for the district for last week amounted to 8769 tons of ore, valued at $219,225.

Storey County

The output of the Comstock mines for last week amounted to $42,658, of which the North-end mines produced $39,175. The Ophir was in the lead, with a production of 361 tons of ore assaying $53.75 per ton. The Ophir output, however, is a little below its usual production owing to retimbering done on the 2100-ft. level.

Washoe County

Ore consisting of almost pure silver, so soft that it can be battered into any shape, has been found by the Nevada United Mines Co. in the Wedekind district, according to newspaper reports. When the vein was found in the new shaft the ore taken from it assayed about $50 per ton, but later developments have resulted in finding ore of steadily increasing value. On the surface the foundation for the hoist will be completed in a few days.

White Pine County

Reports from Ely state that the Giroux Con. M. Co. is planning to increase the capacity of its concentrator to 1000 tons per day and to build a railroad from the Bunker Hill mine to the plant. The sulphide zone near the Bunker Hill shaft, where it crops to the surface, will be stripped. The railroad is to be completed before severe weather comes. Retimbering the Morris No. 2 shaft is in progress. Two churn-drills will be used to find the extent of the orebody.

NEW MEXICO

Socorro County

(Special Correspondence.)—At the Deadwood mines extensive development combined with the regular mill tonnage is taxing the capacity of the present hoist to the utmost. During this development period the management has decided to devote a portion of the mill to treating custom ores.

The ore treated by the Ernestine M. Co. the past week amounted to 700 tons, from which a concentrate product of 50 sacks was obtained. The frame for the new 20-stamp battery is being erected, the mortars for which are on the way from Silver City.

The Mogollon Gold & Copper Co. has made arrangements with the Deadwood management to handle 20 tons of ore per day from the Little Charlie mine, which has been producing shipping ore for some time. The rock will be packed on burros, a distance of about a mile. This extra tonnage will allow the Deadwood mill to operate at about full capacity during the next few months.

Mogollon, October 27.

SOUTH DAKOTA

Lawrence County

Ore assaying $12 per ton has been discovered by A. T. Roos and John Treber on the Mascot group of claims in the Two Bit district, according to recent reports from Deadwood. The group of claims includes 185 acres. Two Bit creek, which runs through the property, will be used for power in the event of erecting a mill.

UTAH

Juab County

The Uncle Sam Con. M. Co., which owns four-fifths of the 500,000 shares of the Richmond & Anaconda company, is planning to prospect the latter property, which has been idle for years. The Uncle Sam is now developing a vein parallel to the orebody which has supplied the company with the ore. The properties, which adjoin each other, are in the Tintic district.

The Iron Blossom Con. M. Co last week paid out in dividends $70,000. This figure, according to recent press reports, brings the total of dividends paid by Utah mines in 1911 to $5,169,687. The Iron Blossom has paid in dividends this year $230,000 and a grand total of $930,000.

MAP OF UTAH.

While the exact value of the production of the Iron Blossom mine for September is not known, it has been estimated at about $70,000. More conservative figures are $60,000, on a basis of an average net value of $10 per ton for the 5900 tons of ore produced. The drift on the 600-ft. level of shaft No. 3 has intersected ore, although it is not valuable enough to ship. The company has been prospecting for months in this shaft to find the continuation of ores from the 500-ft. level.

The compressor at the Victoria, where the drift on the 1200-ft. level is nearing the vein, has broken down. At the Beck tunnel a drift will be run from No. 2 shaft to get under the vein. At the Swansea the vein has 'pinched' so that it occupies only a part of the drift.

Utah County

The Santaquin King M. Co. has been incorporated to develop property between the Union Chief and the Santaquin Chief in the Santaquin district. An adit will be driven immediately, according to official announcements, to reach the vein recently discovered in the Santaquin Chief and adjoining properties. The company, which is reported to own 17 claims, is authorized to issue 1,000,000 shares of stock, of which 600,000 already have been subscribed. W. D. Rawson, of Provo, is president of the company.

CANADA

British Columbia

T. D. Pickard and associates have secured an option on the Apex group of claims near the Nickel Plate from G. F. Willey of New York, according to recent reports from Hedley.

Ontario

Charles D. Taylor, of California, has bought the controlling interest in the Porcupine Imperial M. Co., state recent newspaper despatches from Porcupine. The shaft at the time of the fire last July was about 100 ft. deep and about 100 ft. of driving had been done. The fire destroyed the surface equipment, but the buildings have been replaced and machinery for underground development is being delivered.

Lionel R. Stuart Weatherley, according to despatches from Porcupine, has paid $15,000 down on a deal for the Preston East Dome company's stock. The transaction was the result of the discovery of what is said to be remarkably rich ore. Mr. Weatherley, who is reported to be British Vice Consul at Nome, Alaska, stated that the mine would in time be one of the greatest gold producers in the world.

MEXICO

Hidalgo

The Compañia Exploradora de Minas will start the construction of a reduction mill and cyanide plant in the Pachuca district in the near future. The company, formerly known as the Andres Tello company, owns a number of properties in the Pachuca and El Chico districts. The reduction plant is to be built at the El Borda mine, a few miles north of Pachuca.

The San Felipe de Jesus company has resumed the extraction of ore. The general clean-up, necessitated by the long period during which the mine was practically closed, has been finished.

The Santa Gertrudis company has invited bids for the proposed new shaft at San Guillermo, says a late report from Pachuca. The shaft, which is to have 5 compartments, will be 27 ft. 10 in. long. No decision has been reached as to whether steel or timber supports will be used.

Sonora

(Special Correspondence.)—There is reason to believe that the Greene-Cananea company will pay a dividend before the close of the year, possibly 40c. per year. W. D. Thornton, president of the Greene Con. Copper Co., would not commit himself to a definite statement as to the dividend, but did give a strong intimation that the report was not without foundation. He said that the mine is in good condition and that the company, having completed extensive improvements to reduce operating costs, there is no reason why dividends should not be paid, unless the copper market dropped to a point below its present level. He added that he looked for an improvement in the market. While Mr. Thornton declined to give the actual cost of production, it is understood that the company is putting copper down in New York at a cost of about 9c. per pound.

Cananea, October 26.

Press reports contain rumors that the Phelps-Dodge interests are negotiating the purchase of the Transvaal mine. Walter Douglas, general manager for the Phelps-Dodge company in the Southwest, is said to have made an inspection and to have made a personal report to James Douglas, his father, president of the company. Mining men in Sonora are reported to greatly desire the completion of the deal, as it is believed the purchase would result in the extension of the Nacozari railroad and the development of all the adjoining district.

The San Pedro M. Co., financed by Massachusetts investors, is to resume work on a larger scale than before, states a report from Clumpas. Apollos Fuller, superintendent for the company, is expected to be at Clumpas in the near future.

Ore assaying as high as $2000 per ton is being mined at the Cerro Gordo, and a shipment will be made shortly. O. L. Neer is superintendent for the company.

PERU

The production of crude petroleum in Peru for 1910 was 175,000 metric tons. The kerosene produced amounted to 1,050,000 gal., and the gasoline and benzine to 155,000 gal. Oil is found in great quantities along the north Peruvian coast, but only a comparatively small part of the field has been developed.

Recent reports state that the Proaño smelter at Tamboraque has stopped operations for the present.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

INJURY TO MINER—CONTRIBUTORY NEGLIGENCE

An experienced miner was injured by a fall of slate from the roof of a mine. It appeared from the evidence to recover damages for the injury, that the injured miner had carefully examined the roof for loose rock, but found it to be sound and solid. After taking out two cars of coal he examined it again and testified that it seemed to be solider than before and believed it to be perfectly safe and that there was no danger that the roof would fall. It was his custom generally to sound the roof after taking out each car, but the roof at this time appeared to be so safe that he only sounded it upon first entering and again upon taking out the second car of coal; and the accident happened about two hours after the last sounding and while he was working on the fourth car of coal. It was the duty of the miner to protect himself against such an accident while working in his own room, and it was the duty of the mine-owner to furnish props when needed. The miner had placed an order for props as he entered the mine in the morning, but the general rule in the particular mine was that props were sent within a day or two after an order was placed, that is, the orders were usually placed a day or two in advance of the need of such props, and there was no claim that the miner believed that he had immediate need of such props; and up to the time of such accident the miner had not discovered or suspected a condition that would require the immediate use of the props, and there was nothing to show that he would have used the props if they had been promptly furnished. The miner testified on trial that he was an experienced miner and knew as well as any man how to sound a roof and when it was beginning to get loose and when it was likely to fall and that he never before had missed in his judgment in respect to such matters and this was his first accident. He also stated that a roof might sound solid at one time and 15 or 20 minutes afterward let loose, and for this reason he usually tested the roof after taking out each car. Under these circumstances it was held that the mine-owner was not negligent in failing to deliver the props immediately, and that the miner was guilty of contributory negligence in failing to sound the roof in accordance to the usual custom after each car and that he assumed the risk which he knew and fully appreciated.

Williams *v.* Norwood-White Coal Co., (Iowa) 125 Northwestern, 232. March 1910.

INJURY TO MINER—CONTRIBUTORY NEGLIGENCE

A miner is not guilty of contributory negligence because of his failure to give notice within a reasonable time of a known defective condition. And such miner working in a mine may assume that the mine-owner has discharged his duty in seeing to it that the place is reasonably safe, and the miner is not required to exercise even reasonable care to ascertain whether the roof of the mine is soft or not, except as he is required by statute to examine the working place before commencing work and to repeat the examination after a stoppage of work during the shift.

Lockhart *v.* Sloss-Sheffield Steel & Iron Co., (Ala.) 51 Southern, 627. March 1910.

MINERS AS FELLOW SERVANTS

Miners engaged in mining operations are fellow servants; and the rule applies although by reason of seniority one servant was director or boss of their operations, and the negligence of such director or boss in failing to get a new rope, or for permitting an old rope to be used by his fellow miners for an improper purpose and for a use to which it had not been put, and the master was not liable even where such boss or director was guilty of negligence.

Avikanen *v.* Baltic Mining Co., (Mich.) 125 Northwestern, 545. March 1910.

Company Reports

ORIENTAL CONSOLIDATED MINING COMPANY

This company is capitalized for 500,000 shares at $10 each, of which 70,610 shares are owned by the company. The report for the year ended June 30, 1911, shows that during that period 342,956 tons of ore was produced by the mines owned by the company, and a further 1141 tons was produced by tributers, having a total gold content of $1,787,629 (corresponding to $5.19 per ton). From this ore $1,541,347 was obtained at an operating cost of $839,858, leaving an operating profit of $701,489. On new construction and development work $28,769 was expended, leaving a net operating profit of $672,720. The balance on hand on June 30, 1910, was $532,791. During the year dividends No. 16, 17, and 18 were paid, amounting to $644,085, leaving a balance on hand June 30, 1911, of $561,426.

At the Tabowie mine the ore reserve is estimated at 410,000 tons, of an average gold content of $4.88. At the Taracol mine the reserve is estimated at 285,000 tons of an average content of $4.57. The Kuk San Dong mines have an estimated reserve of 35,700 of a content of $2.22. The Charabowie reserve is estimated at 47,000 tons of $6.32 ore. At the Candlestick and Chintui mines the ore reserves are estimated at 11,580 tons of $10.75 ore and 13,000 tons of $3.09 ore, respectively. The development work in the Chintui and Kuk San Dong mines was unsatisfactory, and they now appear to be nearly exhausted. In the other mines development work was satisfactory and the ore reserves have been increased during the year. The average operating costs are given as follows: mining, $1.41 per ton; milling, $0.56; treatment of concentrate, $0.15 (cost per ton treated, $1.94); general expense, $0.32; other minor items making a total of $2.53 per ton. The recovery was as follows: bullion from mills, $2.67 per ton; concentrate treatment, $1.69; other minor items making a total of $4.49 per ton. This is itemized as follows:

	Ore mined, tons......	Bullion yield, per ton ...	Net yield, per ton conc...	Tailing, per ton	Net recovery, per cent ..
Tabowie	121,257	$2.26	$2.02	$0.47	84.4
Taracol	85,062	2.30	1.95	0.14	86.3
Chintui	29,637	2.33	1.97	0.41	85.4
K. S. D. North...	28,659	1.85	0.64	0.28	80.5
K. S. D. South...	29,734	1.51	0.53	0.24	80.2
Charabowie	39,610	5.25	1.56	1.22	81.4
Candlestick	8,997	8.14	1.40	0.20	87.5
Tributers	1,411	4.26	3.59	0.81	80.2
	344,097	$5.19	$1.69	$0.49	84.1

There are five mills upon the company's property, as follows: Tabowie, 80 stamps; Taracol, 80 stamps; Kuk San Dong, 40 stamps; Maibong, 30 stamps; Candlestick, 10 stamps; a total of 240 stamps. The average stamp duty per 24 hours was 4.2 tons per stamp. There are four cyanide plants; that at Taracol treated 23,743 tons during the year, yielding $534,199, an average recovery of 86%; the plant at Kuk San Dong treated 5491 tons, yielding $34,194, an average extraction of 66.8%; at the Candlestick plant 7246 tons was treated, yielding $21,964, an average recovery of 53.7%. During the year a cyanide plant was constructed at Kuk San Dong to re-treat the cyanide dump. This plant has a capacity of 80 tons per day, and much difficulty was at first experienced in treating the oxidized concentrate, but the plant is now in successful operation and is making a 58% extraction. The average gold content of the dump is $7, the tonnage available being estimated at 40,000. Some inconvenience has been experienced in securing timber rights from the Japanese administration, but this has been settled by the payment of a reforestration tax.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

WILLIAM H. [illegible] is now at Tonopah.

F. Z. BURNS is on professional business in Cuba.

H. V. WINCHELL was in San Francisco this week.

ERROLL MACBOYLE has returned to San Francisco.

A. C. BINGHAM, of Marysville, is in San Francisco.

F. B. CALDWELL has been at San Francisco during the week.

J. R. CAHILL is in charge of construction work at the Plymouth mine.

J. P. KEENE is testing a placer property at Princeton, British Columbia.

WALTER BALTZ, an official representative of the German Government, is in San Francisco.

L. H. THURSTON, of Dawson, Northwest Territory, is at the Fairmont hotel, San Francisco.

ALBERT BURCH is in general charge of the interests of Bewick, Moreing & Co. in California.

W. H. STORMS has returned from Nevada county, California, where he has been making an examination.

W. B. FISHER has been appointed general manager for the Davis Daly Estates Copper Co. at Butte, Montana.

A. H. CASE has been appointed acting manager of the Tennessee Copper Co.'s plant at Copperhill, Tennessee.

FRANK BURNS has returned from Mexico to resume his old position as superintendent for the Arkansas & Arizona Copper Co. at Jerome, Arizona.

J. V. N. DORR has been appointed general manager for the Mogul Mining Co., succeeding to the position made vacant by the death of W. L. McLaughlin.

H. C. MILLER is examining and testing the ore of the Pilot Knot Mining Co., Gottville, Siskiyou county, California, preliminary to installing a cyanide plant.

A. D. FOOTE has sufficiently recovered from the operation which he recently underwent in San Francisco to be able to return to his home, where he is making good progress toward recovery.

E. W. MCCRARY, formerly with the U. S. Geological Survey, has formed a partnership with F. M. HUTCHINSON, under the firm name of Hutchinson & McCrary, with offices at 712 German Bank building, Marietta, Ohio.

THE JUNIOR CLASS IN MINING of the Colorado School of Mines spent from October 18 to 21 inspecting the placer and lode mines in the Breckenridge district, Colorado. They were accompanied by Professors Schneider and Allen.

Obituary

EDWARD L. BALLOU died at his home at Igo, California, on October 1. A native of Illinois and a graduate of the class of 1876, University of Illinois, he removed to Shasta county, California, over thirty years ago, where he engaged in mine operation. He was a competent miner and a good citizen; he can ill be spared.

HORACE H. EMRICH was shot by an unknown assassin on October 17, at Kyshtim, Russia. He was born in New York in 1880 and graduated from the Colorado School of Mines in 1903. Both before and after graduation he had extensive experience at the Colorado smelter at Pueblo, which was operated by his uncle, Anton Eilers. Later he was employed at the Perth Amboy plant of the A. S. & R. Co., where he rose to be superintendent of the copper department. Early in 1910 he became superintendent of the electrolytic refining department of the Kyshtim Corporation, Ltd. He was popular both with his associates and subordinates, and the motive for his assassination is unknown.

Commercial Paragraphs

The Mine & Smelter Supply Co., of New York, Denver, Salt Lake City, El Paso, and the City of Mexico, has acquired the exclusive agency for the Holman drill in the United States and Alaska.

Hammond & Co. has succeeded Samuel F. Hammond as representative of Eastern manufacturers engaged in the iron and steel industry and has opened offices in the Story building, Los Angeles, California.

The Kennicott Co., of Chicago, reports the sale of 24 Kennicott water softeners to the Peruvian Corporation, Ltd., for use on its railways in Peru. These water softeners will have a capacity of 5000 gal. per hour.

The Pacific Foundry Co., San Francisco, has been appointed the representative of the General Chemical Co. to handle the Herreshoff Roasting Furnace in the States of California, Nevada, Utah, Washington, Oregon, Idaho, Wyoming, Arizona, and New Mexico. The Pacific Foundry Co. will send to any one interested an attractive bulletin describing this furnace and also literature on its Kilker Matte Tapping Car.

The Byron Jackson Iron Works has won its suit against the United Iron Works of Oakland, California, for infringement of patents on automatic counterbalance centrifugal pumps owned by the plaintiff. This case has been pending for the past two years. The city and county of San Francisco recently purchased $120,000 worth of these pumps from the Byron Jackson Iron Works for use in its auxiliary salt-water fire system.

The Goldfield Con. M. Co. paid a dividend of 30c. per share on October 31. The operating profit for September was $444,366.

The Bunker Hill & Sullivan M. & C. Co. paid on November 4, 1911, dividend No. 170 of $65,400. This makes the total amount of dividends paid $13,094,250.

EDITORIAL

GATHERING of the Atlantic fleet in New York harbor on November 1, upon thirty days notice, holds an element of astonishment even to patriotic Americans. A hundred vessels, twenty-four of them first class battleships, formed a fleet that only Great Britain could surpass. On the same day twenty-four ships of the Pacific fleet were reviewed at Los Angeles.

IT IS rumored that E. A. Hitchcock will resign from the office of Postmaster General. Apparently the proposal to send *The Review of Reviews* by freight, while the *Wine and Spirits Gazette* traveled in mail cars, was a little too much. But it must be placed to his credit that, for the first time since 1883, the department showed a profit, of $219,118, on the operations of the fiscal year ended June 30.

JOURNALISM lost a notable exponent in the death of Joseph Pulitzer. Even the younger generation can remember the time when *The World* and *The Sun* were the interesting expressions of vivid personalities. New times are upon us now, and journals are, like corporations, without any tangible personality. Mr. Pulitzer's influence lives after him in many ways and the school of journalism at Columbia University, for the creation of which he provided ample funds, is a fitting memorial to a great editor.

ANNOUNCEMENT is made that Mr. Waldemar Lindgren has been appointed Chief Geologist of the United States Geological Survey, and the mining profession will hasten to congratulate both Mr. Lindgren and the Survey upon the choice. Mr. Lindgren has been identified with the Survey for over twenty-five years, having more recently been in charge of economic geology, and having reorganized the division of mineral statistics. A graduate of Freiberg, he is best known to miners by his lucid reports upon the ore deposits of California, Idaho, Arizona, and Colorado, and engineers will regret if the executive duties of his new work prevent his engaging in field work that has proved so valuable to the profession.

NEW election methods in San Francisco have proved successful beyond expectation. At the primaries P. H. McCarthy, who had been an exceedingly unsatisfactory Mayor, was defeated and James Rolph, Jr., elected. At the general election on Tuesday a city administration in sympathy with the Mayor-elect and his policy was elected without any confusion. This is pleasing evidence that the majority of citizens will demonstrate their honesty and level-headedness when given a fair chance. It is time for San Francisco to put away graft and the domination of the unintelligent, and gird her loins to meet the demands which her destiny will make upon her with the opening of the Panama Canal and the expansion of commerce upon the Pacific.

MANHOOD suffrage in England will probably be introduced at the next session of Parliament. The Premier has been memorialized in favor of equal suffrage for both sexes, but woman suffrage in England does not seem an immediate possibility, being a matter which excites vigorous discussion in the 'tight little isle.' During the recent voting upon constitutional amendments in California the expression most frequently heard was that women might as well be given the ballot, as there would be no end to the agitation until they were. A more serious argument against it is found in the allegation that it will add disproportionately to the low-class, purchasable vote of large cities, accentuating the present complaint that the lower class of citizen votes early and often, while the business man and merchant too often see in election day only an opportunity to arrive earlier at the golf links or shooting ground. California is the first State with large cities within its borders to grant woman suffrage; the outcome will be watched with interest.

PHOSPHATES are becoming subjects of great interest, both because of the demand for superphosphates in agriculture, and because the resulting increased market for sulphuric acid offers a possibility of dealing with the SO$_2$ content of smelter fume. We recently published a description by Mr. M. W. von Bernewitz of the manufacture of superphosphate in Western Australia, and in this issue Mr. James A. Barr describes the phosphate industry of our own Southern States. Only of recent years has the widespread occurrence of phosphates in the United States been fully realized, as the extensive deposits of the West were not at first recognized as such. It now seems not impossible that the United States may some day hold a position in the phosphate trade similar to that occupied by Germany in the potash trade and Russia in the platinum industry. Though the industry is thus important there is little likelihood of quick fortunes being made in it. Phosphate rock sells in Eastern and Western markets at the rate of about 60 cents per unit per cent of available phosphoric acid, which in many places corresponds to the cost of mining plus the freight, though high-grade phosphate from Eastern deposits brings as much as \$4 to \$5 per ton f.o.b. the mine. Natural phosphates are of little use as plant food in the raw state, though the greensands of New Jersey and other States have long been quarried by the farmers and applied directly to the soil, producing plentiful crops. Ordinary phosphate rock is insoluble and must be treated with sulphuric acid to convert it into 'superphosphates' of somewhat indefinite composition before it is of service to the plant. The United States Geological Survey has published some thirty papers upon phosphates, of which the most recent, Bulletin 470-H, deals with the deposits of Idaho, Montana, and Wyoming.

IN REVIEWING for its readers the causes of the outbreak in China, the *Literary Digest* quotes the expressions of opinion of more than a dozen English journals, but not one from the United States. Various reasons might be offered for this, the most adequate, perhaps, being that no American journal had opinions worth quoting. The great dailies of England, such as the London *Times* and the Manchester *Guardian*, keep themselves well informed on progress throughout the world, and make an effort to obtain reliable information, where the American demand is for sensation. It must further be said, in extenuation of the great amount of misinformation regarding the Chinese rebellion recently published in America, that it may result from too great attention to Cantonese opinion, since nearly all the Chinese in the United States, with the exception of students and officials, are Cantonese of the merchant and coolie classes. The Cantonese, though clever and progressive, are of a reactionary temperament; they are the Sicilians of the Orient, and are about as representative of the Chinese Empire as the French Canadians are of the British Empire. For years they have been restive under the rule of the Manchu dynasty, and it is not unnatural that they should claim an influence in the present uprising, which is actually due to widespread dissatisfaction throughout the Yang-tze provinces with the policy of the Peking Government in regard to the nationalization of railways and incurring of foreign loans, greater than actually pertains to them. The Manchu dynasty will probably fall, it has long been tottering, but its overthrow is due to its inadequacy, not to its nationality. What the outcome will be is unsafe to prophesy. A constitutional monarchy seems most probable, but the man of the hour has not yet made his appearance. If this opportunity had come to Yuan Shih-kai twelve years ago he would have met it boldly, now he seems to fear the outcome, and the Government grows daily more disorganized. The need for a strong man is urgent, for the situation is critical. The interests of foreign powers in China are vast and are jealously watched, while the finances of the Empire, long in a precarious condition, and only recently exhibiting a more hopeful outlook, have now relapsed, and it seems probable that their last condition may be worse than their first. It behooves the leaders of the revolutionary movement in China to be careful, lest worse things than government by the Manchus befall them.

Some Words and Their Uses

The Mining Magazine has recently urged editorially that the loose use of 'fine' and 'coarse', as applied to alluvial gold, be discouraged, and suggests that the standardization committee of the Institution of Mining and Metallurgy issue a pronouncement giving to these words a degree of precision befitting their use by scientific men. We are inclined to go farther, and suggest that gold which is in small particles be described in some way not involving the use of 'fine'. 'Fine' gold is universally recognized as gold which is free from impurity, and some explanatory phrase is required if the reader is to infer that the attribute is physical rather than chemical. On another page there appears an interesting note by Mr. Waldemar Lindgren showing that placer gold in California is finer than that occurring in quartz veins. The first impression conveyed by the word is here the correct one; the placer gold is purer. It would be better to limit 'fine' to this meaning, when applied to gold, and thus avoid confusion of ideas. A cynic has said that the use of language is to conceal the absence of ideas. Though perhaps this is true of the language of diplomacy and polite society, the scientific man employs language to express ideas with conciseness and precision. Words of a double meaning add to the zest of casual conversation, but in technical speech they usually lead to profitless confusion.

'Proposition' has generally been reserved for technical use in mathematics and logic, though it has a wide variety of meanings. Americans, with their characteristic fluidity of speech, have dragged it into common use, for the numerous and elusive reasons which impel them to give new meanings to old words and to invent new phrases. Many of these are distinct acquisitions to speech, but all are subject to a spurious popularity which often leads to a looser and looser usage that finally ends in their abandonment by careful writers and speakers. 'Proposition' is already well advanced in this downward stage and is daily more loosely used by those from whom better things might be expected. We hear of business propositions, dredging propositions, a new scheme of legislation is referred to as a proposition, and so on, *ad nauseam*. A proposition is the result of a setting forth, and is therefore abstract; there is no necessity for applying it in a concrete sense. A sufficiency of words to express such ideas already exists; by using 'proposition' we are degrading from its high estate a word which has retained a definiteness of meaning that can ill be spared.

Carlyle invented new words and employed old ones in new senses in order to give a ponderous appearance of dignity to his style. A similar procedure is followed by many Americans to produce an opposite effect, and under suitable circumstances the result may be a satisfactory one. But due attention should be paid to suitability of circumstance, a judge may use forms of speech when playing with his children that would be unsuitable in an utterance from the bench. And too few realize the difference between oral and written language; a difference which is real and marked, though not so great in English as in some other languages, such as Chinese. A dental practitioner does not attempt to perform all his work with one tool, but employs a great number, each of which is nicely adjusted to its task. A practitioner of the art of expression should not be less well equipped.

Alaska and Its Problems

Alaskan problems have been prominent in the court of public opinion for some time, and, rightly or wrongly, public opinion, at first inchoate, has begun to take on rude form. Elsewhere in this issue Mr. Duncan M. Stewart discusses the problem of transportation, and its bearing on the future of Alaska, and Mr. George Otis Smith discusses the coal land laws, a collateral phase of the Alaskan problem. With much of what Mr. Stewart presents we find ourselves in cordial disagreement, with the rest we agree, and in any case the views of a citizen of Alaska deserve a hearing. A "no doubt but ye are the people, and wisdom shall die with ye" attitude of mind is conducive neither to progress or enlightenment. Our own views upon Alaskan problems have already been presented and need not be reiterated here. To us the real issues at stake appear more vital and fundamental than whether certain trails and railroads are to be built, whether coal and copper mines are to be developed, by whom, and how. The problems of Alaska are like a cake of soap which has caused the discharge of the geyser of widespread and deep rooted dissatisfaction with our system of public land laws, with the part which large aggregations of capital have played in the development of natural resources, and the methods by which governmental control of public lands and natural resources has been exercised and extended. Let us discuss these briefly in their order.

The public land laws are admirably treated by Mr. Smith upon the following page. Mr. Smith is lenient. It is not perhaps too much to designate our public land laws as a hodge-podge, evolved out of what of Roman civil law and the civil law of England was considered germane. Precedent is the guiding star of legal procedure; lacking its guidance in the solution of the problems arising out of the disposal of the immense areas of public land existing in the United States after 1803, blunders were the natural result. These at once created precedents, and there has grown up a shapeless mass of legislation that hampers progress. The state of development of the United States in 1910 was, in 1810, utterly incapable of conception, as far beyond realization as the distance to the moon. Yet a general scheme of legislation formulated in the early days of the Republic now limits the directions of growth.

Large corporations, like Home Rule, seem a topic incapable of temperate discussion; on the one hand we have 'muck-raking' magazines, on the other the Chancellor of Syracuse University. Yet nothing is clearer than that the part which large corporations, and their responsible heads, have played in the history of politico-economic development is one neither provided with horns and a tail, nor with a golden crown and harp. Large aggregations of capital developed because the need for them arose. Social problems of a great city are different from those of a country village—the social problems of 1911 are similarly different from those of 1861, and no amount of argument concerning the wisdom or unwisdom of past procedure will meet the needs of the present day. In the evolution of society we have come to a stage where the transaction of business in large units is an economic necessity. Once "Adam toiled and Eve span, who was then the gentleman?" Also the clothing trade was then restricted to fig leaves, and there was no Department of Agriculture, nor a Reclamation Service. We have now reached a much higher stage of development; one in which court orders commanding large corporations to disintegrate are as futile as the orders of King Canute to the sea. Ultra-conservatism cannot hold back progress, let it hang upon her skirts so much as it will. On the other hand, there is a strong public feeling that for the average citizen to be obliged to approach the heads of railroad and other public service corporations with bared head and a humble request for fair treatment upon his lips, and to have his necessities of life taxed to furnish disproportionate profits to corporate enterprises, differs but little in appearance and less in principle from the relation between the serfs and the barons of the Middle Ages. The barons had their power shorn from them, nothing is more certain than that the American people will not permit themselves to be overreached and exploited, even if it be necessary to keep business and industry in constant turmoil for the next half-century to prevent. For the present unsettled condition both sides are to blame; large corporations have frequently employed their power in illegal and unjust ways; the public, having found the corporations guilty in certain respects, now suspects them of every crime in the calendar and refuses to allow them any larger measure of freedom than they at present enjoy. The resulting situation is much like that of the soldier who caught a Tartar, the assistance of a third party is needed.

Neither have the functions of governmental control, as exhibited by Government officials, been without fault. In the endeavor to make shift with the faulty system of legislation, men who have engaged in the work of the development of natural resources have been led into subterfuges and evasions in the effort to comply with the law. On the other hand, Government officials, to prevent what they, correctly or incorrectly, regarded as attempts to take undue advantage of the faulty law, have been led into courses of action quite as devious and illegal. A horse, which has fallen in his harness, may in his struggles to arise, kick the shins of the men who are endeavoring to assist him. There has been good faith and honest endeavor on both sides of this matter. But those engaged in the development of mineral wealth are prone to forget that the days when the virgin treasures of the Great Plains and the Sierras were awaiting men with the energy and courage to win them are gone, never to return. It is idle to talk of developing Alaska by methods followed in Colorado and California; such methods were but a rough and ready makeshift, ill-suited to the days of 1851, and quite outgrown in 1911.

And at the root of the whole matter lies too great self-interest. It must be put to the credit of monarchical forms of government that they gave us *noblesse oblige*. A democratic form of government tends to substitute the phrase, 'look out for number one.' Public lack of faith in the efficiency of legislation as a remedy for national problems takes root in a public belief that Congress is largely composed of the representatives of interests, corporate and private, and that the golden motto of so-called statesmanship is 'scratch my back and I'll scratch yours.' In our public life today we have too few men who are known and believed to have a disinterested regard for the common welfare of the whole body politic. May their tribe increase!

What the West Needs in Coal Land Legislation

By George Otis Smith

*In any discussion of the needed revision of the public land laws, a due share of attention must be given to the statutes relating to the coal lands. While certain classes of lands in the Western States have largely passed into private ownership, the public's holding of coal lands is still large enough to deserve most serious consideration. West of the one hundredth meridian lies the Nation's greatest coal reserve, estimated at more than a million million tons of anthracite, bituminous, and sub-bituminous coal, and title to 60 to 85% of this tonnage is in the United States. It is self-evident that this fuel reserve is the key to the present and future industrial development of the Rocky Mountain region. Utilization of the water-power resources will be an important factor locally, and for several decades fuel oil may be expected to affect the industrial situation, but so far as we can foresee coal must be regarded as the principal source of power. Its present importance is shown by the fact that the coal production of the Rocky Mountain States was 14.7% greater in 1910 than in 1909, although for the whole United States the increase in coal output for the same period was less than 9%. Utilization of these Western coal deposits that will meet both present and future demands is the end that must be served in whatever public policy is adopted. The West needs and has a right to demand full opportunity for legitimate, energetic business development, but that does not include the right to inflict an unearned speculative tax on the future consumer.

Full opportunity on the public coal lands can be defined both from the standpoint of the coal operator and from the point of view of the consuming public. In my opinion the operator can justly ask two things: First, the right to occupy an acreage sufficiently large for economic operation during an average mine-life period, and, second, freedom from too great investment risks. Economic operation will be understood to mean installation of such equipment as will secure maximum recovery at low cost with proper safeguarding of both life and property, while excessive investment risks refer to capital outlays out of proportion to expected profits of operation. Both of the factors are in reality of hardly less interest to the public than to the operator, for upon them depend in the last analysis much that determines prices and concerns general welfare. The public should also demand that no right to the public coal land shall be granted except for present use. Actual development must be made the first condition of occupancy of any part of what now remains in the public domain.

The present status of coal mining in the West is the resultant of two factors, land ownership and consumptive demand for coal. The large holdings of coal land legitimately acquired through railroad grants and those secured by coal companies through dummy entrymen, and by purchase of agricultural entries as well as those patented to the States as non-mineral lands, together constitute a coal land supply that has practically met the demand. The strict administration of the public domain during the past few years, however, has shut off all opportunity for wholesale accumulation of coal lands under cover of the homestead and other laws. Up to the present time the acquisition of the coal land in the public domain has been largely accomplished without recourse to the coal-land law, so that the question becomes opportune—is the present coal-land law adequate to meet present and future needs?

This law relating to coal lands is less unsatisfactory than many of the mineral land laws now on the statute books. By its provision for the valuation of coal lands at an adequate price the law makes possible a selling price that may promote development and at the same time prevent monopolization. As is pointed out in a public statement by Walter L. Fisher, the present governmental policy of basing the valuation of public coal lands upon the tonnage and quality of coal which underlies the tract results in prices that are neither unreasonable nor exorbitant; the purchaser instead of paying a flat rate per acre in reality pays for the coal by the ton at values graded according to the quality and the character of the coal. Consideration is also given to every known physical and commercial factor affecting the value of the coal of the particular locality. The purpose has been to protect the present interests of the West by making the selling price of coal land approach, but in no case exceed, the present purchase value of a royalty under a lease-hold, such as the States of Colorado and Wyoming or land companies in the West grant to the lessee, and at the same time to protect the future interests of the people by having these prices such as to discourage long-time speculative holdings. We must always keep in mind the fact that large speculative holdings are sure to affect the future price of coal in two ways; through the possibility of monopoly, and through the certainty of accumulated interest charges on the cost of the idle land.

The test of any policy is in the results it produces. That the prices put upon the public coal lands are not prohibitive can be shown by the record of sales. In the four years following the adoption of the policy of classifying and valuing the coal lands, the sales have increased 12½% in acreage and 36% in value as compared with the four years preceding, and this in spite of the fact that the four years since July 1, 1907, have included a period of industrial depression and slow recovery as contrasted with the preceding period of boom conditions. So far, therefore, as its provision for pricing is concerned, the present law appears to be as satisfactory as a sale law can be.

One serious defect exists in the present law which, all must admit, demands an immediate remedy. The restriction of legal purchases to a maximum of 160 acres for an individual or 640 acres for an association is absurdly out of accord with good mining practice. The fixed charges of a modern coal mine equipped so as to safeguard life and property and to secure maximum recovery are too high to be assessed against the tonnage of so limited a tract, especially where the coal seam is of moderate thickness. Furthermore, unless provision is made for commercial operation on the remaining lands, too great an advantage is secured to the land-grant railroads and the large coal companies already in possession of considerable areas of high-grade coal. There is no public need of having either individuals or large corporations acquire large acreages of these lands for long-time holding without development. Nor is there any sound economic reason for the disposition of the coal lands in small tracts. The homestead law expresses the spirit of American institutions in that it has encouraged every citizen to own a home, but there is neither sentiment nor sense in a proposal to sell at a low price 160 acres of coal land to an individual, for every citizen does not need to own a coal mine.

In the endeavor to discourage long-time speculative investment in the coal lands, and at the same time permit present development, the fixing of selling prices has involved difficulties. It has been recognized that an ideal adjustment of values is well-nigh unattainable for many, if not for most, coal lands. These difficulties suggest the wisdom of considering the other method of disposition, namely, a leasing system. As Mr. Fisher has stated: "It may well be that a liberal, but wisely protected leasing law would be found to promote development more vigorously than any system of outright purchase." Thus, under a leasehold law, any uncertainties as to quantity of coal or as to costs of operation would not need to be so critically estimated in advance. There would be no necessity of discounting every possible future condition, but periodic adjustment of rate of royalty could insure all equities of both operator and public, and I should expect

---

*Address delivered at the American Mining Congress, Chicago, 1911.

that such adjustments might as often be downward as upward. Under a leasing system, too, it would be comparatively easy so to adjust the relationship between ground rental and royalty as to prevent the acquisition of coal deposits until actual operation became profitable. The greatest advantage of the lease system to the operator directly, and to the public indirectly, is relief from the large capital outlay now required in the acquisition of the large acreage absolutely necessary for a modern mine. This argument advanced against the present policy of valuing the public coal lands at even conservative prices thus becomes an argument for a leasehold law.

The objections to a leasing system are of two classes: those based upon political theory and those based upon economic considerations. Under political objections I will place the arguments so often put forward against Federal landlordism, namely, that the Eastern coal lands were disposed of in fee, and that the West deserves the same treatment; and further, that the natural resources of the West should not be made a source of profit to relieve the Eastern taxpayer. Such arguments can be easily answered. Past mistakes are poor precedents for future blunders. The citizen who argues for the continuance of the liberal, wide-open, public-land policy of the past is apt to be one who wishes a middleman's profit on a small investment, and we know that, East or West, the owner of coal lands acquired as agricultural lands, or in any other way, at a low price, makes his large and unearned profit out of the coal operator and, through him, out of the public. Too large a percentage of the coal output of this country is now mined under lease to justify this objection to allowing the people themselves to lease direct. As regards the argument of reserving Western resources for the West, too few people in the public-land States realize that, under the present system of sale, the proceeds from the coal lands go directly into Western development through the Reclamation Fund, and cannot be used to relieve the Eastern taxpayers except as the whole country benefits by the agricultural development of these public-land States. It is reasonable to expect that any leasing law would make similar provision for the local use of revenue resulting from leases, and indeed several of the bills already introduced in Congress have specifically recognized the wisdom of such disposition.

Much more worthy of consideration are the objections to the lease system based upon the fear that the cost of coal to the consumer would be increased; but I regard this result as altogether improbable. The royalty paid into the United States Treasury can be no greater a tax upon the consumer than the royalty paid to the State of Colorado, or to the railroad land company, or to the farmer. The average price of bituminous coal at the mine, in the United States last year, was $1.12, which usually includes either a royalty or an equivalent interest charge, either of which would probably be greater than any Government royalty. This amount forms so small a part of the price to the consumer that the royalty under a Federal lease could be of but little concern to the public, if, indeed, it resulted in any increase in the first cost of the coal. However, considering the lease as contrasted with sale outright to the coal operator, the reduction in capital necessary for original investment and the elimination of many of the risks in such investment, must result in reducing cost of operation to the mine-owner, and thus make possible a correspondingly lower price to the consumer.

The other objection to the lease system is that based upon fears of expensive Federal management, and of inefficient administration or even maladministration. These are possibilities which we must squarely face; but my faith in the efficiency of public administration is increasing to such a degree that this argument against leasing is rapidly losing its force with me. Looking beyond our own Rockies, and out across the Pacific, it may be seen that a Governmental leasing system for coal lands is not a theory but an actual working fact. The Anglo-Saxon peoples of the Australasian States have found the leasing system not only practicable, but indeed preferable to the sale of coal lands. In New Zealand, where for thirty years the laws have permitted to the operator a choice of either sale or lease of public mineral lands, a conclusive argument for the leasing system is given in the latest statistics of mineral production, which show that approximately 90% of the total mineral product of that country was mined under leasehold. If our transpacific neighbors can administer a lease law so satisfactorily, and if the mine operators in New Zealand prefer operation under a leasehold, will a similar system be fraught with either danger or failure in the United States? The fact must be faced that Uncle Sam is a landlord on a large scale—a coal baron, if you please—and that the question before us is how these millions of acres of coal land are to be disposed of so as to serve the just needs of the operator who offers his capital, technical skill, and business experience, asking in return a fair profit, and at the same time to protect the public interests.

All that the West needs is, first, opportunity for the coal industry to develop as fast as the market justifies expansion, and with the least possible risks; and, second, opportunity for the public to secure its coal at prices based on a minimum cost of production and without any addition of unearned or undue tribute to private landlords who desire to speculate on the future needs of the consumer. These ends I believe can be best attained by legislation inaugurating a Federal leasing system for coal lands of the public domain.

Development of the Steel Rail

By William J. Boucher

Robert L. Stevens advocated the use of an all-iron rail, in preference to the wooden rail plated with strap-iron, then in use on some of the American railways. At that time there was no mill in America capable of rolling such rails, and as the Birkenshaw rail, with which the best English railroads were then being laid, required an expensive chair to hold it in place, it was not adapted to conditions in America, where metal-workers were scarce and iron was high in price. Stevens accordingly devised the base to the T-rail, thus dispensing with the necessity for the chair. He also designed the hook-headed spike (which is substantially the railroad spike of today), and the 'iron tongue,' which has developed into the fish-plate or angle-bar, and the rivets (which have been replaced by bolts and nuts) to complete the joint. Thus, with his all-iron rails, spiked to wooden ties, he first produced the type of track which is in general use throughout America at the present time. Much difficulty was experienced in obtaining a mill to roll the newly designed rail, for not only were no suitable rolls in existence and the cost of their making was large, but there was also much doubt as to the practicability of rolling such a shape. An iron-works in Dowlais, Wales, however, was prevailed upon to attempt the work, Mr. Stevens being required personally to guarantee payment for damages to the rolling machinery in case of a breakdown. On coming from the rolls, the rails were crooked and twisted, but, by persistence, he showed the mill-men how to straighten them while they cooled. The first rails weighed 36 lb. per yard, but the weight was soon changed to about 40 lb. per yard, and they were rolled in 16-ft. lengths, being 3½ in. high, 2⅛ in. wide at the head, and 3½ in. wide at the base. With the exception of slight alterations in the proportions, incident to the increased weight, the rail as designed by Mr. Stevens and first used in the Camden & Amboy track, is the rail of today. The price of these rails, in England, was £8 per ton, and the import duty was $1.85 per ton.—*Proc. Am. Soc. Civ. Engineers.*

No location can be made upon an Indian reservation unless allowed by a specific Act of Congress, but a location existing at the time the reservation was created and closed to further locations, has been upheld by the Land Department as being a part of the public domain excluded from the reservation.

An Australian Pump-Dredge

By Charles Janin

A method of treating gold-bearing alluvials that has been used with considerable success in Australia is the centrifugal pump-dredge, or pump hydraulic sluicing-plant, as it is also, and perhaps more properly, called. In this country the centrifugal pump has been successfully used on suction dredges for harbor and reclamation work and for tailing pumps on some of the gold dredges; also for elevating gravel in ground-sluicing where the ground lacks sufficient fall to provide the proper sluicing grade and when sufficient water is not available for a hydraulic elevator. Centrifugal gravel pumps were also used both in Montana and California on the old double-lift elevator dredge where the material from the buckets was dumped into a water-tight compartment built on the dredge hull, and raised therefrom by the pump to a straight sluice extending some distance behind the dredge.

While the use of the centrifugal pump for supplying water under pressure and for elevating gravel in sluicing is familiar to gravel miners, little is known in California of the pumping plant as a dredge, and indeed most California operators would not consider it a dredge at all, as it differs so widely from the modern dredge as used in California. The pump-dredge, instead of floating on a pond, like an ordinary dredge, and excavating gravel below as well as above the surface of the water, operates while resting on dry land and elevates by means of a centrifugal pump to sluices, placed at sufficient height to obtain the required sluicing grade, the gold-bearing material which is hydraulicked from the gravel banks near the dredge to a sump in front of the dredge.

It is obvious that the pump-dredge cannot be used as a substitute for the bucket-elevator dredge, nor can it be compared with the latter, either in efficiency or operating cost, but, on areas too small, or otherwise unsuited for a bucket dredge, but which contain a sufficient gold content to make it economically possible, a pump hydraulic plant may sometimes be used to good advantage. Where sufficient water, under natural head, is obtainable, a hydraulic elevator may in some cases be found more efficient, and under certain conditions a bucket drag-line excavator of the Bucyrus, or similar, type could no doubt be used to better advantage. The selection of a plant to work a given area is properly determined by a careful study of the conditions under which it is to operate. The pump plant seems well adapted to small areas unsuitable for ordinary methods of operating where the gold content is sufficiently attractive, and where the amount of water in the gravel is not too great to be handled by the pump, and where it is necessary to elevate the gravel to obtain a sluicing grade. A pump-dredge might also be used where water is scarce, or where it is necessary to hold the tailing in settling ponds in order not to conflict with an anti-débris law. In such cases, the low cost of installation makes it a popular machine in Australia, where plants of this type have been successfully operated for a number of years.

Following is given a short description of the centrifugal-pump dredge, and two illustrations which give a good idea of its adaptability. These photographs are of particular interest, as they show how thoroughly the bedrock can be cleaned. The centrifugal-pump dredge is built on a pontoon and rests on dry land while working, though it can be floated to a new point of attack on a property when found advisable to change the position of the plant, if enough water is available to make a flotation pond. The pontoon is generally 40 by 50 by 4 ft. in depth on the large plants, and 30 by 40 ft. on the smaller ones.

PUMP-DREDGE AT WORK.

The equipment consists of two centrifugal pumps, either driven by the same or by separate engines, the most approved type being driven by independent engines. Pumps are sometimes run in series coupled when a high lift is necessary; one plant in Australia raising the gravel over 100 ft. by this means. Steam is generally the motive power, but electricity is used whenever available. If water under sufficient pressure is not available for hydraulic purposes one pump, generally from 10 to 14 in., supplies a 4-in. hydraulic giant or monitor under sufficient pressure to

Table Showing Operation and Working Cost of Centrifugal-Pump Dredges or Pump-Hydraulic Sluicing Plants in 1910. (Adapted from Government report for Victoria.)

wash down the bank and sluice the material to a sump in front of the dredge. From this sump a 10 or 12 in. centrifugal gravel pump, which is generally steel lined, on account of the great wear caused by sand and gravel, elevates the material, from which the boulders and larger gravel have first been screened, to the riffled sluices. This operation is somewhat similar to that of the pump on the old double-lift type of dredge. The sluices are placed either above the dredge or at a convenient point on the bank, and after the material has passed through the sluices the tailing is conveyed to the settling pond. If desirable, the excess water is returned to the section of the pump supplying the giant. The amount of water required depends to a great extent upon the nature of the ground to be worked. It has been estimated that a minimum of about 2500 gal. is necessary for each cubic yard raised by the pump. The water that is used in the giant is pumped with the material washed to the sluices, and this water can then be returned to the pump which supplies the giant, a continuous supply making up for evaporation and seepage.

CLEANING ROUGH BEDROCK.

There were 46 of these plants in operation in Australia during 1910, working an aggregate of 3,947,796 cu. yd. of material, with an average working time of 16 weeks per dredge. One dredge operated 48 weeks and two 46 weeks, the others ranged from 4 to 28 weeks each. The average recovery from ground worked was 3 grains, or about 12c. per cubic yard, and the working costs of all plants averaged 11.2c. per cubic yard. These figures are taken from the Government report on dredging in Victoria for 1910. The accompanying table, which was made up from figures taken from this report, gives details of operations of several of these plants. The dredge having the largest capacity washed an average of 12,284 cu. yd. per week at an operating cost of 10.9c. per cubic yard. Mention is made in the Government report of a dredge washing 24,000 cu. yd. per week at an operating cost of 34c., but, as it only operated six weeks, it was not considered that this was representative of actual conditions and was therefore not used in the tabulated statement given here.

As with bucket-elevator dredges, numerous failures are reported from ill-advised installations, either on areas unsuited for such equipment, or where the gold content is not sufficient for profitable work. However, there are undoubtedly areas unsuitable for a modern dredge installation that can advantageously be worked by some modified form of dredging, and, if the gold content is sufficient, a centrifugal-pump dredge or one of the other methods previously mentioned might be advantageously used. Certainly the equipment of a property should not be advised before a thorough examination of the ground has been made. Having all the necessary information, the selection of a proper plant will depend upon the judgment and experience of the engineer.

Relative Value of Quartz and Placer Gold

By Waldemar Lindgren

*Observations in all parts of the world have shown that placer gold is always finer than the gold in the quartz veins from which the placers were derived. The explanation, as has been shown in a most convincing manner by Ross E. Browne, among others, is that the silver alloyed with the gold is dissolved by the action of the surface waters. The purity of the gold becomes greater as the size of the grains diminishes, the explanation being, of course, that the proportionate amount of surface exposed to the action of solutions is greater in the finer gold. An interesting confirmation of this view is recorded by McConnell, who states that examination of nuggets from the Klondike shows that their surfaces consist of gold of greater fineness than their insides. Some interesting data on the fineness of California gold have been contributed by F. A. Leach and C. G. Yale. A few of these data, which were obtained from mint returns for a period embracing several months of 1898, are mentioned below. The average fineness of the gold of Nevada county is given as 855; of Placer county, 792; of Plumas county, 851; of Sierra county, 858; of Calaveras county, 835; of Tuolumne county, 804. This includes both placers and quartz mines. The finest gold produced in California is that from the San Guiseppe quartz mine, near Sonora, Tuolumne county. This gold runs from 982 to 998, or $20.63 per ounce. On the whole, however, the gold from quartz veins is decidedly lower in grade than that from placers. The highest average of fineness in California is that of the gold from the placers at Folsom, Sacramento county, which runs from 974 to 978. The gold from the dredging areas of Butte county, near Oroville, is also of high grade, averaging about 922. At the localities cited the gold is obtained mainly from Quaternary deposits in the present rivers.

In Placer county the quartz veins carry gold of a fineness from 580 to 921. In the main channels of Tertiary gravels may be noted the Morning Star mine, at Iowa Hill, where the gold is 900 fine; the Big Dipper, on the same channel, 884; Michigan Bluff, 940 to 970; the Red Point drift mine, 927; and the Hidden Treasure mine, on the White channel, 924 to 941. In Eldorado county the quartz gold varies from 570 to 901 in fineness. At the Excelsior claim, at Placerville, one of the principal channels, the gold on the bedrock had a fineness of 925, while that in an upper stratum at the same place, on 'false bedrock', reached 975. The gold in the Snow mine, above Placerville, a gravel deposit in the main Tertiary river, runs 948 fine. A drift mine at Grizzly Flat, on a small Tertiary stream near the headwaters and near some quartz veins, runs 871 fine. In Calaveras county the quartz vein yielded gold ranging in fineness from 627 to 885; one exceptional quartz mine near Angels Camp shows a fineness of 960 to 975. The gold in the gravels of the main Tertiary river draining this county yielded at Vallecito gold from 940 to 987 fine. In the Green Mountain hydraulic mine, at Mokelumne Hill, the fineness was 919.

The figures quoted show clearly that in the main Tertiary streams a considerable refining of the gold has been going on, so that the average grade is decidedly above 900. It is difficult to compare accurately the tenor of the gold in the present streams with that in the Tertiary channels, for it must be remembered that the former contains a mixture of detrital gold derived from Tertiary channels with much new gold set free during the erosion of the present canyon system.

Mineral Production and Resources of China—II

By Thomas T. Read

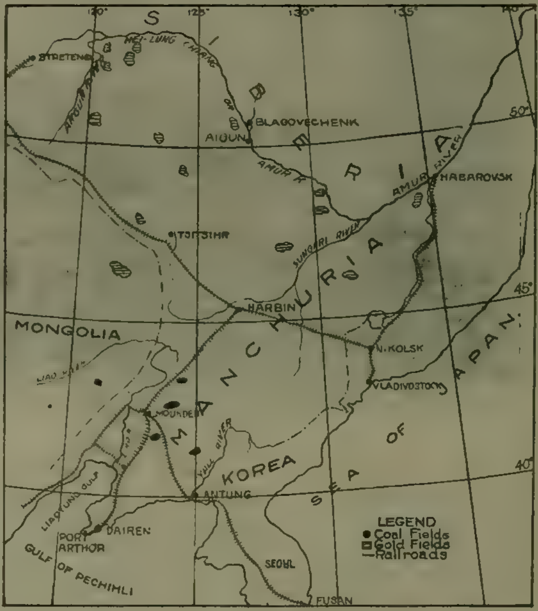
(Continued from p. 450.)

*Gold in China has unusual interest at this time, since the proposal to place the coinage of the Empire upon a gold basis is now receiving more serious consideration. The fact that the gold production is so small has always acted as a strong deterrent to the establishing of a gold coinage. Since China produces but little of either gold or silver, and must purchase them with exports of merchandise, the advantage of buying silver at its present low price is apparent. At present silver and copper are the media of exchange, the former passing at an approximation to its bullion value, while the copper *t'ung-tz'erh* and cash are subject to daily fluctuation of value. As each province now issues coins, which pass only at a discount, or perhaps not at all, in other provinces, the transaction of business is subjected to a wholly unnecessary burden. The central government having acquired control of the railways, will doubtless next proceed to complete its present shadowy control of banking, and a gold standard may be introduced, as large amounts of foreign capital are now invested in China, and interest payments are at present subject to sudden and extensive changes in the rate of exchange.

The absence of records of mineral production renders it difficult to obtain any knowledge of the gold production of the Empire. The best approximation can be made from the customs records of gold exported, since the amount used annually in the arts is but small. The export for 1908 was approximately $6,500,000, that for 1907 was $3,200,000. The occurrence of gold in China has been noted by Baber, Garnier, Duclos, LeClere, Hoover, Hosie, and others, but the most notable descriptions are by Hoover, Hosie, and Purington. The last has described[1] at length the occurrences of alluvial gold in northern Manchuria, along the Amur, Sungari, Tumen, Urga, and Nonni rivers and their tributaries, and its recovery by primitive washing methods. Gold also occurs in southern Manchuria, both in alluvial deposits and in narrow veins, frequently of the gash type. The Bureau of Mines of Manchuria has compiled a list of ten localities where gold is worked in Fengtien province, and forty others where it is known to occur. Bogdanovitch has published an excellent study of the deposits of the Liao-tung peninsula, dividing them into four classes: (1) existing stream beds; (2) Pleistocene high-level gravels; (3) ancient valley alluvials; (4) marine placers. The northern area is of much greater importance. It will perhaps be safe to estimate that Manchuria produces from 75 to 80% of an annual output of from $5,000,000 to $7,000,000 for the whole Empire. According to Russian reports, the Tuschetuchanovsky and the Tzetzenchanovsky gold properties in Mongolia have yielded, between January 1 and August 20, 84 poods[2] 10 funts 7 zolotniks of gold. This compares with 87 poods 38 funts 82 zolotniks in the corresponding period of 1910.

The gold-deposits of Chili have been described by Hoover. These are widely scattered, the most notable being veins at Chin-Chang-K'ou (119° 56′ E., 42° 20′ N.) and at Chuan-Shan-tze (119° 12′ E., 42° 26′ N.). In 1910 the former was producing at the rate of $150,000 per year and the latter $15,000 annually. There are numerous placers throughout the province, and Hoover estimated the total production for 1908 at $1,000,000. In Shantung similar conditions prevail, except that the deposits are not so abundant.

The best-known mine in China is that of Chou-Yuen, about 40 miles southwest of Chefoo, where a quartz vein from 40 to 90 ft. wide has been uncovered for more than a mile in length. Curle states that 200,000 tons of ore, worth $10 per ton, has been developed. The ore is about 40% free milling, and many years ago a chlorination plant was in operation upon the tailing from the stamps. The mine has been closed for many years, by Government order, but there has been constant effort on the part of foreign companies to secure the concession, and recently the governor of Shantung petitioned the Peking Government to allow the Chinese owners to operate the mine, fearing lest it might otherwise be lost. The nearby mines at P'ing-tu are probably of considerable value. In spite of the Government prohibition of mining, a certain amount of work is carried on quietly, and Hoover estimated the gold production of Shantung at $12,000 annually. With the few exceptions noted, there seems little probability that deposits of sufficient size can be developed to justify the construction of modern milling plants, the cost of labor being so low that primitive methods give cheaper working costs. The tailing from the chlorination plant, mentioned above, was bought by the neighboring farmers, who carried it home and, in the dull season of agricultural work, ground it in native mills and panned it. The deposits near Wei-hai-wei have been described by Verschoyle, but are of little importance. In northern Manchuria, which has not been adequately prospected, large-scale workings may perhaps be developed, but throughout the rest of the Empire progress is likely to take the form of increase and improvement of native workings, efficient and inexpensive pumps being the most-needed equipment of native mines. Hansen has recently reported that between Lanchow, on the western border of Kansu, and the border of Thibet numerous placer workings exist, carrying as much as 2 gm. of gold per cubic yard. Quartz veins also occur, containing 1½ to 2 oz. gold per ton, but as these statements are apparently based upon the reports of Chinese, they must be received with caution. A modern stamp-milling plant is now in course of erection near Lanchow.



GOLDFIELDS OF MANCHURIA. (After Purington.)

Throughout the rest of the Empire, quantities of gold are produced in many places, most of which are known to be of little importance. Ssu-chuan and Yunnan have been of much interest, since they are but little known.

*Abstract of a paper presented at the San Francisco meeting of the Amer. Inst. Min. Eng., October 10 to 17.

[1] 'Northern Manchuria.' *Mining Magazine*, January 1911, p. 53.

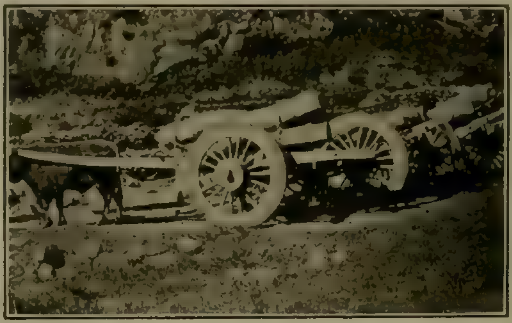
[2] One pood of placer gold is worth about $9000.

The upper waters of the Yang-tze are known as the Chin sha or 'golden sand,' but this does not necessarily indicate, as has been assumed, that especially rich alluvials exist along its course. Many travelers have mentioned the known or rumored existence of gold deposits in these two provinces—LeClere, Duclos, Baber, Hosie, Garner, Jack, and Johnston, to name but a few—but definite information is only meagre. At Mo Lo in Ssu-chuan (102° 05′ E., 28° 15′ N.) important quartz deposits have been worked since 1880 by a combination of foreign and native methods. Small quantities of alluvial gold are reported from a great number of places, but in nearly every case the name of the district is given in such a way that identification is difficult or impossible. In giving the native name of little-known places, either the Chinese characters should be employed, or else the latitude and longitude should be given. In Yunnan the most notable mines are at Ta-lan-tung (101° 45′ E., 23° 30′ N.), at an elevation of 7300 ft. These quartz-veins in Paleozoic rocks are worked by native methods, yielding some $60,000 per year. At Kin-Kiang, 60 miles from Ta-li-fu, rich conglomerate beds are worked by the natives. On the maps prepared by La Mission Lyonnaise the following places are marked as productive of gold: Ssu-chuan (99° 36′ E., 30° 55′ N.), (99° 45′ E., 30° 40′ N.), (99° 55′ E., 30° 20′ N.), (101° 50′ E., 32° 40′ N.), (101° 40′ E., 32° 0′ N.), (102° 15′ E., 31° 40′ N.), (102° 0′ E., 29° 0′ N.). Yunnan (98° 45′ E., 23° 45′ N.), (99° 50′ E., 23° 20′ N.). (These are degrees east of Paris, not of Greenwich.) Numerous other localities are mentioned in the references given, and with the great recent increase of transportation facilities in Yunnan it is not at all impossible that the gold-mining industry will greatly develop.

Gold is known to occur in Kansu, and there are quartz veins in the upper valley of the Han-ho in Shensi. Along the lower reaches of the Han-ho, in Hupeh, there is a small amount of gold washing constantly carried on. The same is true of Fukien, where in the Shao-wu district, 150 miles northwest of Foochow, valuable deposits are said to exist. In Anhwei mines were formerly worked, and deposits are known to exist in Hunan and Kwangsi, but they are not much worked. The mines in Kwangtung are said to be valuable, but in all these cases it is probable that the deposits are limited in extent and of no great richness. It may be said, in conclusion, that with the exception of Manchuria and the southwestern provinces of China (Yunnan and Ssu-chuan) the gold-mining industry gives but little promise of growth. In the districts mentioned the introduction of modern pumping machinery and the removal of the restrictions which the authorities and superstition have placed upon the industry is likely to lead to a considerable development.

Silver

Silver is of great interest in China, since it is the chief medium of exchange. But the domestic production of silver is small, and China is, accordingly, a heavy buyer of the metal. An interesting subject for speculation is found in the source of supply of this metal during the period when China maintained but little communication with the outside world. About the time of the beginning of the Christian era there was a great deal of traffic with the countries on the southwestern border, where the mining and smelting of argentiferous galena seems to have been a considerable industry, and the Burma Mines, Ltd., is now engaged in exploiting ancient silver-lead mines at Baudwen, 60 miles west of the Yunnan frontier. The best-known silver mines are those in the northern part of Chili province, near Jehol. At the time when Li Hung-Chang was viceroy, foreign engineers were employed in their exploitation. Woo, who has described the native methods of mining and smelting these silver-lead ores, which occur as veins in quartz-porphyry associated with Paleozoic sediments, says that the lack of success of the foreign enterprise was due to the high cost of the coke used and to the unsuitable character of the milling machinery employed. The general and probably correct impression is that these veins are too limited in extent and too irregular in character to allow of their being worked with a profit upon a larger scale than that employed by the natives. The production in 1903 was estimated at from 80,000 to 100,000 oz. per year. In the mountains to the west of the line of the Peking-Hankow railroad, numerous small occurrences are known, but the production is probably insignificant. References to the occurrence of silver in nearly every province may be found, but do not seem to warrant much attention. Duclos mentions numerous places in Yunnan where silver is produced, being usually associated with lead and zinc. The production at 'Pei-cha po' he estimated as 10,000 oz., and says that small amounts are produced at 'Koung-chan', 'Fou-lay-tchang', 'Siao in-tchang', 'Tchou-tsin-tchang', 'Sin-pao-tong', 'Ta-lang-tchang', 'Tchen-pien-tchang', 'Mo-lay-tchang', and 'Sin-tchang' in Yunnan. At 'Tsai-tse-chang' in Kweichou, silver is obtained from an argentiferous galena. At 'Mou-pin' in Ssu-chuan an argentiferous galena containing a little gold occurs; silver is also found toward the north of the province, at 'Pe-tsoa-pa' and 'Hou-koua-tou'.



ONE METHOD OF TRANSPORTATION IN THE ORIENT.

On the maps prepared by La Mission Lyonnaise the following places are marked as productive of silver: Ssu-chuan (101° 45′ E., 32° 10′ N.). Kweichou (104° 20′ E., 25° 12′ N.), (104° 35′ E., 25° 05′ N.), (104° 15′ E., 28° 10′ N.). Yunnan (98° 45′ E., 23° 45′ N.), (99° 50′ E., 23° 20′ N.), (101° 0′ E., 26° 30′ N.). Kwangsi, (106° 55′ E., 23° 0′ N.). Kwangtung (108° 20′ E., 21° 40′ N.), (109° 45′ E., 22° 20′ N.), (110° 50′ E., 25° 10′ N.), (111° 0′ E., 24° 50′ N.), 111° 05′ E., 22° 20′ N.), (112° 15′ E., 22° 50′ N.), (114° 05′ E., 23° 25′ N.), (114° 05′ E., 24° 15′ N.).

A Chinese company is now mining silver at Kwei-Hsien in Kwangsi. The Jun Wah Sut Yip Co. was organized a few years ago, with native capital, to develop silver and other mines in Kwangsi, and is carrying on extensive exploration and development work. Several foreign companies have attempted the development of silver mines in southern China, but without much success. It must be admitted that, on the whole, silver mining in China is of no great importance.

Copper

Copper has always been an important metal in China, as brass and bronze, employed for objects of use and adornment, and as media of exchange, have played a prominent part in the national life from the earliest times. But in the case of copper, tin, nickel, zinc, and lead, the discussion of the metals separately offers difficulties, since the ores are associated and are often smelted together, giving rise to natural alloys. By far the most important supply of these metals is derived from the southwest. Yunnan is the most important, but copper also occurs in the neighboring regions. Duclos gives a long list of places where copper is produced in Yunnan and describes in some detail the work at San-Kia-Chang (99° 35′ E., 24° 40′ N.), where he estimated a yearly production of 42 tons. LeClere has summarized as follows: "The total production obtained by reduction with charcoal was, in the seventeenth century, at least 6000 tons, but has decreased to from 1000 to 1500 tons. The decrease is not due to the impoverishment of the deposits, but to the disappearance of the forests, the scarcity of fuel permitting only the exploitation of deposits of unusual richness at the places most favorably situated in respect to transportation. The copper minerals are various. Phillipsite, cantonite, and more rarely cupriferous pyrite are found in veins in the Carboniferous schists, but are almost abandoned. Sheets of cuprite with barite, and of native copper, intercalated in porphyrite, are highly esteemed, but the lack of explosives often makes it impossible to work them. Sandstones impregnated with copper carbonate are often found in the Trias. The principal deposits are in Triassic limestones; the network of veins has been converted into carbonates, with only a trace of pyrite. The principal mining centres are: (1) 'Toung-tchouan' (101° 0′ E., 26° 30′ N.), the mines in Ssu-chuan, near the Blue river, are connected with these; (2) 'Oui-si,' near Li-Kiang (97° 15′ E., 27° 15′ N.); (3) the neighborhood of 'Ouei-ning' (102° 15′ E., 26° 45′ N.), in Kweichou, produces zinc and lead principally, and is directly governed by the mining official of Yunnan-hsien. The works will not take ores of lower grade than will give a smelting mixture of from 20 to 30% copper; the latter is more common. This richness is obtained by careful hand-sorting at the mines. The ores lower in grade than 15% are piled up and form large dumps. The old slag-dumps are common near the old smelting centres and contain about 3% copper. These facts demonstrate that Yunnan has extremely large resources of copper minerals, especially in the parts not workable by native methods." There are Government mines at Pai-shui-ho, in the Pêng-hsien district of Ssu-chuan. An Anglo-French syndicate has a concession to develop the mineral resources of seven of the prefectures of Yunnan, but has been unable to proceed because of local opposition.

Copper occurs in many other parts of China. While in Kiangsi in 1908, the local officials told me of a large copper mine at Chang-pai-ling in the west-central part of that province which had recently been extensively developed, but was not successful. Clark has described the copper ores of Lao-Pao-chi in Anhwei; this is probably the area which was subsequently granted as a concession to Lord Lister Kaye. Clark also describes the production of copper by native methods near Jehol (118° E., 40° N.), and I have seen unimportant native workings in many other places. C. H. Hansen, who has recently been engaged in the work of constructing, under Government auspices, a 50-ton copper smelting plant at Yao-kai, 70 miles west of Lanchow, on the western border of Kansu, states that there are numerous mines within a radius of 80 miles from that point. The ores are said to yield 7.5% copper.

The mining of copper has always been rigorously under the control of the Government, probably because of the importance of the metal as a medium of exchange. The native supply has not been equal to the demand for many years, and considerable amounts are imported, chiefly from Japan.

Nickel

Nickel is of much technical interest because of the ingenious way the Chinese have of smelting mixtures of nickeliferous copper ores with tin, lead, and zinc ores, forming the alloy *pai-t'ung*, or *pakfong*, as it is called in southern China. This is a kind of german silver, which is extensively used in the manufacture of candlesticks and other household objects. Nickel is never produced separately, and the entire supply is apparently drawn from southwestern China, where in Yunnan (100° 20′ E., 28° 50′ N.), and in Ssu-chuan (100° 20′ E., 26° 45′ N.), Duclos has noted the occurrence of nickeliferous copper ores. The mines at Hui-li-chou, in Ssu-chuan, are under Government direction.

Tin

China is an important producer of tin, furnishing at present about 5% of the total production of the world. A certain amount of the product comes in native boats down the Yuen and Hsiang rivers, probably originating at some point in Kweichou. Kwangtung also produces a notable amount, which is exported through Wuchow. On the maps prepared by La Mission Lyonnaise the following places in Kwangsi and Kwangtung are marked as productive of tin: (105° 10′ E., 24° 12′ N.), (110° 15′ E., 24° 45′ N.), (110° 45′ E., 22° 15′ N.), (112° 0′ E., 23° 30′ N.), (112° 45′ E., 22° 50′ N.), (114° 10′ E., 23° 40′ N.). There are also deposits in Fukien, and a small amount is shipped from Foochow. But by far the larger part of the production comes from the well known mines at Ko-ch'in-ch'iang (100° 50′ E., 23° 20′ N.) in Meng-tze-hsien, Yunnan. Here the deposits, which LeClere says "*ne sont nullement alluvionnels: leur origine filonienne est des plus evidentes*," are scattered over an area 25 miles long and 20 miles broad, and 30,000 workers are engaged in mining and smelting the product of 150 mines. The workings are both surface and underground, and only native methods are employed. Collins, Duclos, and LeClere have described these deposits in detail. Theoretically the deposits belong to the central Government, which, according to the mining regulations, exacts a royalty of 25%, but the amount actually paid is somewhere between 12.5 and 18%. The reports as to the production of these mines do not agree, but the customs returns for 1909 was 4700 tons, corresponding to about 90% of the total production for the Empire. The crude tin, in slabs weighing 74 lb. each, is exported to Hongkong, where it is refined. A large part of the tin was formerly shipped down the Yang-tze and West rivers, but now it is shipped over the French railroad. Recent newspaper reports are to the effect that efficient smelting and mining machinery is to be installed by a native company, about $1,200,000 having been subscribed for the purpose, and the erection of a slag-cleaning plant has been proposed. It is not unlikely, therefore, that the production of tin in China will considerably increase in the near future.

Lead

There is a considerable demand for lead in China, which is largely met by imports, 10,707 metric tons of pig lead having been imported in 1908. The domestic production is not inconsiderable, lead ores occurring in 8 of the 18 provinces; Kweichou, Ssu-chuan, and Yunnan are the most important, but about 1500 tons of ore was derived from Hengchou and Yangchou prefectures in Hunan province in 1908. The larger part of this is exported to Great Britain and Belgium, but considerable quantities are smelted at the works of Carlowitz & Co. at Wu-chang. Three hundred and fifty tons of pig lead was brought down the Yang-tze through I-chang in 1907, and 300 tons in 1909. A good deal of lead ore comes down the Yuen and Hsiang rivers, both from Hunan and Kweichou. Duclos has described the production of lead at 'Tcha-tze-tchang' (102° 50′ E., 26° 45′ N.) in Kweichou, and notes its occurrence at (102° 40′ E., 26° 30′ N.). In Yunnan the mines contain mixed ores of lead, zinc, copper, and silver. In the neighborhood of 101° 0′ E., 26° 30′ N., at 'Kong-Chan-tchang', 1,450,000 lb. of lead is produced; at 'Pe-cha-po', 700,000 lb. of lead; at 'Koung-chau' the lead produced is cupelled for silver. Near 102° 20′ E., 26° 45′ N. there is a considerable production, both of lead and zinc. In many places argentiferous lead ores are worked (see 'Silver'), the bullion being cupelled; the resulting litharge often being thrown away. LeClere estimated the annual production in southwestern China at around 3000 tons. The lead ores of Kwantung and Kwangsi are mentioned under 'Silver.' On the maps prepared by La Mission Lyonnaise the following points in Kwangtung are marked as productive of lead: (109° 50′ E., 21° 58′ N.), (110° 15′ E., 23° 57′ N.), (114° 05′ E., 23° 58′ N.). The native methods of metallurgy are so imperfect that it is not improbable that in many cases deposits exist which could be worked by modern methods. But, as mentioned under 'Silver,' it has not infrequently been found that the veins are too narrow and irregular to yield a profit when exploited on a large scale.

Zinc

The whole domestic supply of zinc in China is derived from the southwestern provinces, chiefly Kweichou. Duclos has described the native metallurgical methods followed at 'Ma-lou-kio' (102° 50′ E., 26° 45′ N.), and mentions the occurrence of zinc in Yunnan at (102° 20′ E., 26° 45′ N.) and (101° 40′ E., 25° 30′ N.). LeClere says that the workings are only superficial and that the distillation methods are so imperfect that much ore which could be utilized by modern methods has been discarded. He estimated the annual production at about 2500 tons. The spelter from Kweichou, which I have seen, was obviously impure, but it is used in the provincial mints in making brass coins without any attempt at refining.

Antimony

China possesses the distinction of being first in the production of this metal. The condition of the industry has been changing rapidly of recent years. My notes were made on a visit to the chief centre of production in 1908. The ore comes from a number of places to the northwest of T'ung T'ing lake in Hunan, I-yang being the chief centre (110° E., 29° N., approximately). It is carefully hand sorted at the mines and is brought in native boats to Changsha (112° 45′ E., 28° 15′ N.), where it is liquated in pots of about 15-in. diameter. The methods were entirely Chinese at that time, but I understand that furnaces of modern construction have since been installed by the Hua Chang Antimony Co. of Changsha. The regulus is sent to Hankow, and so much as desired is converted into metal. The residues have been exported to France, Germany, and the Netherlands for further treatment; more recently large quantities have been sent to the United States. Carlowitz & Co., who operate a smelter at Hankow, are also engaged in the work of smelting and refining both antimony and lead, but as strict secrecy is observed, details are not obtainable. The production for 1907 from this district in Hunan, according to customs returns, was 3957 tons of regulus and 14,810 tons of ore. In 1908 the production of regulus increased to more than 8000 tons, and the ore shipments decreased to less than 2000 tons. The native company which operates the smelter has trained metallurgists in its employ, and the industry is likely to further increase in importance.

Antimony also occurs in Kiangsi, Kweichou, and Ssuchuan, but Kwangtung is the next most important province after Hunan. Recently a smelter under Government auspices was established at Wuchou (111° 30′ E., 23° 30′ N.), but was not a success and has since been closed. A more extended discussion can be found in the *Mineral Industry* for 1908 and 1909, and in the volume 'Antimony' by C. Y. Wang (London, 1909).

Quicksilver

Quicksilver has a steady demand in China, most of the metal being used in the production of vermilion, which enjoys high favor as a pigment, a less important use being in gilding by the Chinese method. The native production fluctuates greatly, the amount reported by the customs authorities being 30 tons in 1907, and 65 tons in 1908. It is impossible to determine what relation exists between the total amount produced and that reported by the customs. Most of the demand is supplied by imports, largely from California. The occurrence of quicksilver is reported from many parts of the Empire, but the deposits in the province of Kweichou are, apparently, the only ones of commercial importance. As I have not visited these districts, my information is entirely derived from published statements. Duclos has noted several places in Kweichou where quicksilver is produced; 'Oa-tchouan' (105° 50′ E., 28° 30′ N.), Pei-ma-t'ong (104° 15′ E., 26° 48′ N.), Lan-mou-chang (103° 15′ E., 25° 28′ N.), and Yang-li (104° 20′ E., 25° 0′ N.) are the most important. He estimated the production at Pei-ma-t'ong as 6500 lb. per year, and says that at Yang-li there is "*une enorme exploitation*". He also mentions the occurrence of quicksilver in Yunnan (101° 10′ E., 23° 30′ N.). LeClere was not favorably impressed by the mercury deposits, and remarks, accurately enough, that the native methods of work can treat ore of quite as low grade as would be profitable by foreign methods. Brelich says that the deposits at Wen Shan Chiang in Toon Yen prefecture are the largest and most extensively worked in Kweichou. They occur in nearly horizontal beds of magnesian limestone: (1) impregnating well defined beds, (2) along joints and planes of stratification, (3) in isolated bunches and vugs, (4) irregularly disseminated. The ore is hand sorted and retorted in native furnaces. According to Brelich, the miners work for daily wage, which is unusual. The Anglo-French Quicksilver & Mining Co. began work at Kwei-yang in 1899, with a capital of £310,000, operating the Wen Shan Chiang mines, which are 12 miles north of the Yuen river. These are apparently the mines which Brelich describes. The area of the concession was 4 square miles. Two 12-ton Granitza furnaces were constructed, and the production from 1899 to the end of 1902 was 32,500 lb. of quicksilver and 500 lb. of cinnabar. The company has had a somewhat checkered career, and the concession has apparently never been a profitable one.

Arsenic

Arsenic is of no little importance in China, but detailed and accurate information regarding its occurrence and production is not obtainable. According to the customs returns 5000 tons was produced in 1908, but only 400 tons in 1909. Apparently the ore occurs in or near the principal antimony district (110° E., 29° N.), since the product passes through the same custom house. About 700 tons of arsenic ore from China was imported into Germany in 1908. A recent French report estimates the annual production of orpiment and realgar in Yunnan at 600 tons. This probably obtained from the mines near Chao-chou and Mêng-hua, in Ta-li prefecture, Yunnan. The customs house at Tengyueh reports that 491 tons passed through in 1909, mostly destined for Burma.

Petroleum

The best known petroleum-producing district is in Ssuchuan, where, according to Coldre, in the neighborhood of Yun-hsien (102° 10′ E., 29° 38′ N.) and Fu-chuan (102° 43′ E., 29° 27′ N.) there are 30 to 40 wells, from 1000 to 3500 ft. deep, in which petroleum occurs associated with gas and brine. The gas is employed in evaporating the brine, and the petroleum, which varies from '*blanc de petit lait*' to '*noir*' is burned in crude lamps without any attempt at refining. Duclos describes the wells at 'Tze-liou-tsin,' which is between Yun-hsien and Fu-chuan, nearer the latter, giving the number as about 150, but probably this refers to the total number rather than those which actually produce petroleum. But neither gives any estimate of the amount of actual production. Richard refers to the occurrence of petroleum in Kansu, but does not give the locality.

A field that is of present importance occurs near Yen-chang (110° 0′ E., 36° 30′ N.) in Shensi. A native company has been at work there for some years, has recently constructed a refinery, and is now selling oil throughout Shensi in active competition with the foreign product. I have been unable to obtain reliable detailed information regarding this field, but it is probably of a great deal of importance, since it is rumored that the company is considering the construction of a light railway from the wells to Singan-fu, 200 miles distant. Apparently petroleum occurs only in the western and southwestern parts of the Empire, but in these places a considerable native industry is likely to develop when the areas are provided with adequate transportation facilities.

The aneroid and the compass, for use in connection with railroad reconnaissance, are regarded by some railroad engineers as little better than toys. It is seldom that the railroad engineer has any opportunity to compare aneroid readings with those of a mercurial barometer at a base station. And with instruments delicate enough to give sufficiently close readings, assistants to read them, and methods of obtaining distances and directions sufficiently accurate to determine, even approximately, the possible rate of grade on a long supported line the expense incurred and the time consumed would be very little, if any, less than would be required to run a rough stadia line which would give much more and better information of the kind wanted by the railroad engineer.

The Problem of Transportation in Alaska

By Duncan M. Stewart

*Every Alaskan harbor south and east of Cook inlet is ice-free and open to navigation all the year round. Though the ports of Quebec, Montreal, St. John, Albany, and Buffalo are absolutely closed to navigation during the winter, all of the more important ports of Alaska, excepting Nome, Fairbanks, and St. Michaels are open to winter transportation. Ketchikan, Juneau, Skagway, Cordova, Valdez, and Seward enjoy at least a weekly mail service from the United States, and the last three are situated on harbors that are unexcelled by any on the Atlantic or Pacific coasts. These three places, Cordova, Valdez, and Seward, are the winter ports for Alaska proper. Skagway is an important port, but is mainly used in winter for going to Dawson, which is in Canada, and not in Alaska, as many Americans seem to think.

These three seaports are the logical and natural termini for railroads to the interior—for what we may call trunk lines—but only at Cordova has the steel been laid for any distance. There the Copper River & Northwestern railroad has trains in operation for something over two hundred miles, and has been hauling ore that distance from the Bonanza mines since last April. This is a standard-gauge road of heavy construction, with steel bridges and well ballasted track. This road has opened to the prospector an area otherwise closed to them, and hundreds of people are now living along its route, and towns springing up that were not on the map before this enterprise became effective. This is what is known as the Morgan-Guggenheim road, so popularly believed in the East to be 'bottling,' rather than opening up the country. Yet this road has made it possible for men to penetrate far into the mountains and valleys in search of precious metals that would have been inaccessible without it. Before the advent of this railroad it would take a man many months to get a camp equipment and an outfit of supplies as far into that part of the country as he can now go in twenty-four hours.

At Valdez there is not enough track laid to dwell on the features of railroad transportation there, but that is the starting point of the Government trail to Fairbanks. All roads and trails built by the Government in Alaska are in charge of a Road Commission, under the War Department, and are properly described as military roads. This road, from Valdez to Fairbanks, is one of the best and has been of tremendous importance to Valdez and the country generally in opening up the mining territory tributary to Fairbanks and the Tanana river, and in developing a great gold producing district.

At Seward a standard-gauge railway has been completed for 72 miles and surveyed for 700 miles, including branch lines, through the very centre of Alaska. This road, which is known as the Alaska Northern railway, gives a very efficient electric car service, daily except Sundays for passenger and express freight, with an occasional steam locomotive freight train, as traffic demands. This company does not operate in winter, as it is undergoing a financial reorganization, which, by the way, was brought about by the action of a Federal judge who granted a receivership on the petition of one man, without according a hearing, or even giving notice, to any official of the railway. He appointed his own brother-in-law receiver at a salary of $1500 per month and expenses and then immediately adjourned his court six months, thereby effectively preventing the owners from removing the receiver and re-obtaining the management of their own property. This corrupt judge was removed from office later in punishment for this crime, and that is about the extent of the aid the present administration at Washington has given to this particular enterprise. The passenger traffic of this road is heavy in summer and its right of way affords excellent traveling for dog teams in winter, being used as part of the Seward-Iditarod trail for about eighty miles.

Although primarily intended to tap the resources of the Kenai peninsula, Kuskokwim, Susitna, and Tanana river valleys, the *raison d'etre* of this line now is the coal of the Matanuska valley, which Government authorities claim to be the most valuable of all known coalfields in Alaska. In this section recently Gifford Pinchot traversed part of the survey route of this railway, and had to do so on foot, by the way, which I trust emphasized in his case the desirability of improved transportation facilities. The route to these coalfields is at present only a horse trail. The Government did nothing toward it and it cannot even be dignified by the title of military road. It is an expensive business getting in supplies; in short, there are no transportation facilities. But build a railway into that country, open up the coal mines and operate them, and the people would flock there; a local market for food products of the rich soil would be at once created, and the land would yield plentiful crops to the agriculturalist.

Transportation is the most important problem confronting Alaska today. Others have given accurate, as well as graphic, information about its coal, but let me assure you that there can be no real cure for Alaskan troubles that does not include transportation. All questions affecting the physical development of Alaska are indissolubly connected with the one great question of transportation.

The opening of the coal lands is absolutely essential to the building of railways through central Alaska by private capital. Officials of the Alaskan Northern railroad informed me that they are unable to operate trains hauled by steam locomotives so long as they have to pay $14 or $15 per ton for imported coal, as they do at present, and I understand that competent officials of the Pennsylvania railroad say they could not operate that great system profitably at a coal fuel cost of $12 per ton. At Seward, the terminus of the railroad, private individuals pay $17 per ton for coal, whereas if the Matanuska coal were available the article could be bought for $5 to $7 per ton, and a much better grade of coal at that. While the coalfields of Alaska are withdrawn from entry it becomes a crime (larceny) to use local coal. The anomaly thus created is best illustrated by the plight in which the Tanana Valley railway finds itself. There is an abundance of good steam coal along the right of way of this road, and a scarcity of timber, but it is forced to leave the coal and burn wood at a cost of about $12 per cord.

There are eight lines of railroad in Alaska, with about 500 miles of track. Five of these are purely local, catering to the traffic of the mines in their respective territory. The other three, namely, the Copper River & Northwestern, White Pass & Yukon, and the Alaska Northern are the most important to the country generally, and of these the White Pass & Yukon railroad is the only one affording transportation facilities into the interior of Alaska, by way of the Yukon river, partly through Canadian territory with only 112 miles of track all told. This route to the interior can only be used advantageously in summer, as the Yukon river is frozen in winter. This road, which was a financial success from its inception, was built with English capital and has been of great value in developing American territory on the Alaska side of the border.

What these two railway enterprises have accomplished in the way of developing the latent wealth of certain sections, and much more besides, can be achieved by the building of a trunk line along the projected route of the Alaska Northern railway, and the people of Alaska do not care who builds it; they will extend a hearty welcome to the owners of such a project whoever they may be. There is not a coast town in Alaska today that is not envious of Cordova, because it has a real live road, making its way into the heart of the territory contiguous to that terminus. The people of Alaska differ among themselves on political and economic questions, and they are far from unanimous as to the best method of exploiting its resources, but they are a solid unit on the subject of transportation. They are quite indifferent as to whether private capital or the United States Government builds trunk lines, and good wagon roads, so long as they are built, and that soon.

---

*Abstract of a paper presented at the American Mining Congress, 1911.

But the building of trunk lines, or any other lines, of railroad is not the only essential; there is even a more crying need for good wagon roads. The appropriation for roads and trails in Alaska is woefully inadequate, and the methods of expending it are distinctly bad. I could point to instances where new trails stopped short in the middle of the woods, having reached nowhere because the appropriation for that particular piece of work became suddenly exhausted. I have seen the necessary repairs to an existing Government road discontinued at a critical spot for the same reason, although a surplus remained after the completion of other specific work, but it could not be utilized, under the regulations governing these funds. The adoption of such methods in the building of roads by private capital would end inevitably in bankruptcy and failure. And let me say here that the excellent gentlemen who are charged with the administration of the Alaska Road Commission are not to blame for the unfortunate conditions to which I have alluded. The people of Alaska owe a great deal to the Road Commission for the zeal and efficiency it has displayed and the work it has accomplished in the face of red tape and ridiculously inadequate appropriations. These gentlemen do the best they can, but the results, nevertheless, are inadequate. Some of the Government roads in Alaska are a disgrace to the Nation. Even the Government employees themselves are ashamed of them, and with a view to bringing home to Congress and the people of the United States the wretched results of their efforts, as compared with those achieved under a policy of enlightenment and common sense, they have inserted in some of the official publications issued at Washington illustrations taken from actual photographs of American and Canadian roads in Alaska and the adjoining Yukon Territory. On one page you will see a beautifully smooth, well drained level road, fit for automobiles, while on the opposite page you will see a strip of mud, roots, and rocks, unfit for the use of man or beast, and positively ruinous, both to a man's soul and body.

MINERAL RESOURCES OF ALASKA. (Brooks, 1909.)

In the administration of justice and the building of public roads and trails in the far Northwest, the Canadians have us completely beaten. We have just the same kind of a country they have, yet they have more people and infinitely better transportation facilities on their side of the imaginary border line. Why should this be? I have given you the facts and leave the answer to you. I venture one reply to this question, and it is, that the average member of the Canadian Parliament is in much closer touch with the actual conditions prevailing in his country as a whole—even to its remotest corners—than is the average member of the United States Congress regarding his great country. Indeed, ignorance would seem to be at the bottom of most of Alaska's troubles; ignorance of its immense area; ignorance of its climate and of its ample resources; and, what is worst of all, ignorance of its people. The most widespread misconceptions are probably those regarding its climate and people. The generally accepted notion is that Alaska is a land of perpetual ice and snow, inhabited mainly by Eskimo, while the facts are that not more than one-third of it is within the Arctic Circle, and that the majority of its present population is white—being a mixture of the best elements of the Caucasian race—the same class of red-corpuscled people who placed Oregon, California, and Washington among the great producing States of this Nation. Every trunk line of railroad in Alaska can be operated daily in winter. The White Pass & Yukon railroad runs trains every day in the year except on Sunday; the Copper River & Northwestern railroad runs trains often enough to accommodate the traffic, and maintains its line open the entire winter. The Alaska

Northern can operate on as regular a schedule in winter as in summer, while the Tanana River railroad, which is in 65° north latitude conducts train service all the year round. After dispelling the ignorance and disseminating the truth, after getting these well-meaning people to understand the actual conditions in some measure as those who live in Alaska know them, I believe the adoption of relief measures which will lead to the development of Alaska on a scale commensurate with its size and the importance of its potential resources can be hopefully expected.

The solution of the transportation problem will cause most of our troubles to vanish, but it cannot be solved by [illegible] and abuse, especially of the powers that be. I believe that the President and Secretary of the Interior are alive to the real situation and needs of Alaska, and that they are sincere in their desire to bring order and good out of existing errors, but they and their successors in office are powerless without the support of Congress, and I think that is the real body to address. If the sympathetic ear of a majority in Congress can be obtained, the Government may be authorized to render some assistance to private capital, either by way of guarantee of bond interest, or a land grant, or a coal grant, and thereby insure the building of a great trunk line of railway with which to unlock this treasure box, to the enrichment of the whole Nation. Or, Congress may decide to have the Government build and operate such a line, and thereby retain the key in its own hands. That it will be a paying investment for the owners, whoever they may be, is not doubted for a moment by anyone familiar with pioneer railroading in the Northwest, and particularly so in this country, under an enlightened policy of trail and wagon-road building, which would create feeders and great arteries of traffic for the main line.

In a new country capital, for obvious reasons, expects greater rewards than in older and more settled communities, and with the inducements which are being constantly offered in such countries as Mexico, Brazil, Argentina, Russia, China, and Africa, it behooves us to see that no unnecessary handicaps are placed upon capital seeking investment in Alaska, and above all when such capital is seeking investment in the all-important line of transportation. I believe the enormously enhanced value of properties caused by the building of such a line in connection with a proper system of wagon-roads, and trails, would amply repay the Government for any assistance it might render to private capital in the promotion of such a laudable enterprise. On the other hand, while I am not an advocate of Government ownership on general principles, I have no hesitation in saying that if the people of the United States were to build such a trunk line system for themselves, and operate it on business lines, the return on the investment would be comparable only to that made in Egypt for the people of Great Britain by that far-sighted statesman, Benjamin Disraeli, when he purchased for the nation the shares of the Suez canal which subsequently proved assets of enormous value.

Long before any locomotive was constructed in Europe John Stevens had clearly worked out, in his own mind, the theory of such an application of steam, and the actual form in which it could be advantageously made, as well as the best mode of constructing and working a railway for the use of locomotives. Long before there was any experience to justify his anticipations, he said and published, "that there was no limit to the speed of a locomotive on a rail, but the strength of the materials, indeed it might easily be made to run as fast as a pigeon could fly;" and it is one of the striking incidents connected with the early days of the Camden & Amboy railroad, now part of the Pennsylvania system in New Jersey, that a flock of pigeons, which had settled on the track, being disturbed by the rapid approach of the engine, took wing in the direction the train was moving, and one of them, attempting to cross in front of it, was struck down, thus most literally verifying the prediction made.

The 'Cement Gun' at Panama

An endeavor has been made to use the 'cement gun' process to retard the erosion of the surface of the soft rock uncovered by the excavation along Culebra cut in the Panama Canal, which has been a source of the gravest anxiety to the constructors of this great waterway. This rock is a fine-grained clay transported and deposited by water, comparatively hard when first exposed by the steam-shovels, which crumbles into dirt with alarming rapidity when it comes in contact with the atmosphere.

A great many suggestions have been made as to the best method of dealing with the problem. These range from the construction of the most elaborate retaining walls to the planting of grass seed. However, the Commission decided to make a series of practical tests. One of these consists of a concrete revetment anchored to the rock by means of rods driven into holes previously drilled into the mass. Another section of the same concrete revetment was reinforced with old French rails, of which there are miles on the Isthmus, this fact probably being the primary cause which suggested their utilization for this purpose. This work must of necessity be very tedious and expensive, as a great deal of hand work must be done to remove the weathered surfaces, as well as grading to accommodate the rails and heavy forms for the gravel concrete. The cost of this experiment convinced the authorities that this method would be prohibitive, considering that the Culebra cut is nine miles long and that this soft rock occurs throughout nearly all of its length on both sides of the Canal.

Following the contours of the rock with the 'cement gun' each nozzle man can cover a great deal of surface. The ratio on this class of work was 1200 sq. yd. of surface coated with five men by the 'gun' process in the same time that it took to cover 183 sq. yd. with the forms with fifteen men and a foreman. The 'gun' process used about 1.25 cu. ft. of material per square yard of surface coated as against 10.50 cu. ft. per square yard by the form process. No reinforcing was used with the 'cement gun' process.

Preliminary sluicing is required to remove the soft rock and earth and give a good surface for the concrete to bed on. This is done by the cement gun equipment by simply shutting off the dry sand and cement and using the water stream under pressure.

The sun in this region is, of course, very hot, and to prevent too rapid 'solar dehydration,' as it might be called, the finished work is sprayed every few hours, in the same way that the preliminary sluicing is done. This together with the frequent rains, should lessen the danger from crazing and cracking. The process is analogous to the way in which a housewife seals preserves with paraffine. At present it is not possible to speak positively in regard to the outcome of this application. Future developments will be watched with interest.

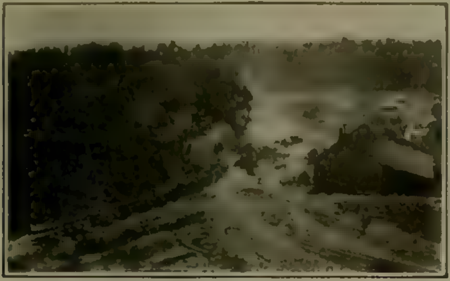
German contractors, according to *Tonindustrie Zeitung*, use a type of cement gun in placing the plastering on large areas of wall space, like those of factories and apartment houses. The cement gun works in combination with a mortar-mixing machine, which mixes the mortar or plaster, as the case may be, in the proper proportions, and drives it, by means of compressed air, into a line of hose from which it is forced against the sides of the wall in a steady stream. The entire portable plant is on a truck, and consists of a mortar-mixing machine, a mortar pump, the compressed-air plant, and the driving motor. The pump takes the mortar furnished by the mixer and forces it into the lines of hose. At the other end of this hose is the nozzle, through which the compressed air from the compressor forces out the mortar at a pressure of 1½ atmospheres. A workman, standing about 5 ft. away from the wall, directs the nozzle and can cover about 1000 sq. ft. in one hour. The pump handles about 70 to 105 cu. ft. mortar per hour, which is sufficient to place a ⅝-in. thick coat of plaster on 1200 to 1700 sq. ft. of wall surface.—*The Cement Age*.

Modern American Phosphate Plants

By JAMES A. BARR

Phosphoric acid is one of the most important fertilizing ingredients of the soil. Since corn removes 11½ lb. of phosphorus per acre for an average crop, wheat and oats 8 lb., and alfalfa 18 lb., it can easily be seen that there is a limit to the producing ability of most soils. As this deficiency of the soil in phosphorus is most conveniently supplied by phosphate rock in some of its numerous forms there will be a growing demand and a good future for the phosphate industry.

There are two distinct types of phosphate rocks in Tennessee; the brown and the blue. This article will first deal with the methods of treating brown rock. This variety of phosphate occurs in platy strata, interbedded with clay and occasionally with limestone and flint pebbles. The clay must be washed out, as the iron and alumina it contains are objectionable in the manufacture of acid phosphate. Flint and limestone lower the grade of the raw material and must also be removed. As a result of several years of experimenting at the Arrow mines the Charleston S. C. Mining & Mfg. Co. has just erected a new phosphate plant at Wales, Tennessee, for washing, drying, screening, and stocking brown rock.



OUTCROP MINING WITH STEAM-SHOVEL, MAYFIELD MINES.

ARROW MINES. WASHING AND DRYING.

The mining is done in open pits by steam-shovels loading into 3-yd. side-dump cars. The heavy stripping will be done by a drag-line excavator, but at present the overburden is light and is being economically removed by wheeled scrapers. The mines are connected with the washer by 3000 ft. of 36-in. gauge track. Two 7 by 12 locomotives are used to haul the rock and serve the steam-shovel. At the washer the rock is dumped from the cars into a spring-roll spike-tooth crusher and reduced to 1½ in. The springs are set so that the flint and limestone will pass through without being crushed. This is to facilitate the hand picking.

From the crusher the material is elevated by an 18-in. rubber-belt bucket-elevator to a height of 50 ft., where it is dumped into the first set of log-washers. These are of the double type and constructed of steel. Here most of the clay and mud is removed and run off at the tail gate. The first set of log-washers discharges into a second set, where the washing is continued with the addition of fresh water. The second set discharges into a rinsing screen, which has a 3-in. spray pipe extending through the centre. The opening in the screen jacket is about ¼ inch.

The oversize from the rinsing screen passes to a slow moving belt where the limestone, flint, and mud balls are picked out. The undersize from the screen, together with the overflow from the tail gates of the washers goes, by means of a series of distributing launders, to 6 riffle troughs, or sand washers. These sand washers are designed to thoroughly elutriate the clay and collect the sand from the large volume of water coming in with the feed. The tail water from the riffle troughs, containing clay and a small percentage of sand of finer size, flows into a primary mud pond where the sand is settled out, the clayey water flowing off through an adjustable gate to a second pond, where the water is clarified before running to the creek or being used over again.

The sand and water from the head end of the riffle troughs flows into a dewatering box, which discharges the thickened pulp on a sloping drainage platform. Here the sand collects in a pile which gradually spreads out from the launder and the remaining muddy water is given an opportunity to flow off through a screen across the foot of the drainage platform. The overflow from the dewatering box goes into a sand bin, of which there are three, 15 by 20 ft., and the sand allowed to settle out. The overflow from the sand bins goes to the primary mud pond.

MAYFIELD PLANT.

MAYFIELD MINES. YARD AND OUTCROP.

The sand from the drainage platform and the contents of the sand bins, together with the rock discharged from the picking belt, is conveyed to drainage piles in the wet-storage space by a clam-shell electric mono-rail trolley. After standing for several days the drained material is removed to hoppers by the same electric trolley. From the hoppers the phosphate is fed automatically to two driers 5 ft. in diameter and 50 ft. long. The driers are driven by direct-connected motors through a system of reduction gears.

The hot rock coming from the driers is elevated to a steel storage tank by a single-strand continuous-bucket chain elevator of 82-ft. centres. From the storage tank the rock is distributed into piles, according to size, in the dry-storage shed by an electric-driven side-dump car. A screen is placed over the storage tank so that it can receive the discharge of the elevator and separate the phosphate into two sizes. The screen jacket is punched with ⅛-in. holes.

The rock from the storage piles is loaded for shipment by an electric clam-shell trolley, either by dumping directly into loading chutes which discharge into a box-car which is placed on a 100-ton track-scale, or upon a cross conveyor which loads cars on a second side track. The rock from the elevator may either be run directly to the cross-conveyor or carried to the loading-chutes by the electric distributing car.

Steam is furnished by two 200-hp. return tubular boilers, operating under 125-lb. pressure. Power is supplied by a 22 by 18 automatic high-speed engine, belted through a counter shaft to a 150-kw. 250-volt D. C. heavy-type generator. The washer is also driven from the main counter shaft. A 1000-gal. capacity duplex-compound pump supplies water under 60-lb. pressure to the washer. A separate 750-gal. duplex pump is connected to the fire lines and can also be used for washing purposes. The water mains are connected to a 20,000-gal. steel tank on a 90-ft. tower, for fire purposes.

The plant at Mayfield is used solely for handling Tennessee blue rock. This variety of phosphate is a tough, granular, bluish rock, resembling limestone. It is not amenable to washing for the purpose of removing the impurities, hence the operations are confined to mining, crushing, drying, screening, and stocking. The phosphate-bearing material occurs in comparatively flat strata, overlying blue phosphatic limestone, and overlain by a shale. The mining is done by the room and pillar system. Much of the rock near the outcrop was mined by blasting the shale and stripping with steam-shovels. Underground the rock is overcut by air-drills and blasted to this face. A low-grade stratum which lies between the phosphate strata and the shale makes this method of mining possible.

The rock cars are taken to the mouth of the adits by mules and are made into trains and pulled to the crusher yard track by small locomotives. On this track the cars run by gravity to an incline, where they are hauled up to the crusher dump by an endless chain. Before being dumped the cars are weighed. The rock is crushed to $1\frac{1}{2}$ in. by a gyratory crusher and fed directly into a 5 by 50-ft. rotary drier. The hot rock coming from the drier is fed to a pair of rolls by a pan conveyor and crushed to $\frac{1}{2}$ or $\frac{3}{4}$-in. size, according to the amount of fine material desired. The discharge from the rolls is elevated by a bucket-elevator to a screen, where it is separated into three sizes.

A cable-operated end-dump car takes the rock from the storage bins under the screen and dumps it into different piles in the storage shed, according to size or grade. All of the rock is loaded by hand into box cars for shipment. In order to supply the demand for ground phosphate a dry-grinding mill is operated, which receives any desired size rock issuing from the screen above the driers. The rock is ground so that 90% will pass through an 80-mesh screen. The mill grinds about 6 tons per hour, with an expenditure of 100 horse-power.

Steam is furnished by a battery of six return-tubular boilers, operating under 100-lb. pressure. The crushing and drying machinery at the receiving end of the plant is operated by a rope-drive from the main counter-shaft, which is belted to a 250-hp. Corliss engine. The remaining machinery is belted direct or through counters from the main shaft. A 2000-cu. ft. double-stage cross-compound compressor supplies the air for the mining operations. There are two smaller air-compressors held in reserve. The electric light system is supplied by a 15-kw. 250-volt D. C. belted generator.

ENGINEERS and contractors of sufficient experience can, by riding over a railroad route, make a fairly close estimate of the probable cost of the grading and bridging. As the result of long experience on many lines in different kinds of country, they can estimate in round figures how much per mile certain lines or sections of lines will cost for the grading and bridging; and, as this represents usually only about 50% or less of the total cost of the complete line with equipment, the other 50% being for items the cost of which can be determined quite accurately with little reference to topographical conditions, any variation in the total cost is usually well within the allowable limits for preliminary estimates. As a method of quickly obtaining an approximate estimate of the cost of a proposed line this has many advantages.

Engineering Features of Steam-Shovel Work at Bingham

By H. C. GOODRICH

*Some time in the eighties the Bingham & Camp Floyd constructed a narrow-gauge railroad so that ore from the district could be delivered to the smelters, then in the valley. The railroad was constructed on a 4% grade, extending into Bingham canyon as far up as the grade would allow. From this point a survey was projected, using a $7\frac{1}{2}$% grade, the average grade of Bingham canyon from the present Denver & Rio Grande depot to the buildings of the United States Mining Co. at the mouth of Bear gulch. A horse tram-line was constructed on this survey, accommodating the Starless, Utah Copper, United States, Commercial, and other mines. About 1890 the narrow-gauge railroad from the valley to Bingham was rebuilt as a broad-gauge line.

I first visited Bingham canyon in 1900. This was the first time I had ever seen freight transported as it was on the horse-tram. A string of twenty or more mules and horses would haul up the small empty ore cars to their several destinations. The drivers would tie strings of these horses together, tail to head, and turn them loose on the wagon-road in the bottom of the canyon. The drivers would then get on the loaded cars, running them down the grade by gravity to the loading station, where the railroad would pick up the ore for the smelter. The horses and mules would be on hand for another haul up the hill. I was sent to Bingham by the Rio Grande Western Railway Co. to reconstruct the horse-tram into a railroad. The instructions were to follow the horse-tram as far as possible, using as maxima $7\frac{1}{2}$% grades and 40° curves. This railroad was constructed from the Rio Grande Western depot to the Commercial mine in the spring of 1901. This was the first standard-gauge railroad that was built to the mines in Bingham canyon. It is necessary to use a special type of engine for these grades and curves, the one most commonly used being the Shay. In 1903 a branch line was built up Carr fork to the Yampa mine and later extended to the Boston Consolidated ore-bin. About this time the Utah Copper Co. began building a mill of 800 tons capacity at Copperton, and other mines were actively producing.

These details are in order to show that the style of railroad originally built for the handling of the Commercial mine ore was not able to handle the tonnage later turned out by the various mines. The United States, the Highland Boy, and the Yampa had to construct aerial tram lines down to the main railroad in order to get their product to market. The Utah Copper, Commercial, and other mines were not able to dispose of the ore they were mining on account of the limited capacity of this road. It is an expensive railroad to operate, and while probably better than a horse tram, one should hesitate before adopting it for handling freight in large quantities.

The Utah Copper Co. in trying to take care of its output, made surveys at different times for a railroad on lighter gradients and curvature from its mine to the mill at Copperton. These plans finally culminated in an entirely new site for its mill and a great deal larger capacity. This radical change in the location of the mill and its large tonnage necessitated a low-grade railroad with light curvature which must be built right into the orebody. The Boston Consolidated was trying out several plans for its property, finally building its mill in the Garfield district, which necessitated handling of this tonnage over the new line. The Denver & Rio Grande Railroad Co., formerly the Rio Grande Western Railway Co., started the location and construction of this railroad in the spring of 1905. I had the pleasure of having charge of the construction of this line from the Utah Copper mine in Bing-

---

*A paper read before the Utah Society of Engineers.

ham canyon to the American Smelting & Refining Co. plant at Garfield. In order to handle the construction material at the mills, it was deemed advisable to start the work of building the railroad to the mills first, while the location at the Bingham end was in progress. This construction work was completed in November 1906. During this time several plans had been under consideration for the Bingham end and extensive surveys had been made. Finally a plan was adopted using 2½%, compensated grade and 16° maximum curves. This line was completed on January 2, 1907, when the first train was run over the new line to the Utah Copper mine.

In describing the operations at the Utah Copper mine, I will confine myself to the steam-shovel operations and railroad construction only. Prior to my connection with the company, it had been decided that this ore could be extracted more economically and a larger saving could be made by using steam-shovels. The orebody is one large deposit, covered with capping from 40 to 200 ft. thick. The problem is to remove the capping from the ore and deposit it on ground away from the orebody, and remove the ore to the railroad yards below. These operations extend vertically from elevation 6340 to elevation 7840, or 1500 ft. All of this territory was not embraced within the property of the Utah Copper Co., but plans were being formulated on a broad plane to handle the property economically. Owing to the steep, thicky populated canyon it was found, on account of the expensive railroad construction, that the economical height of the steam-shovel benches should be not to exceed 75 ft. This has proved to be correct, and wherever it has been found possible, the levels have been made a lesser height. The machine shops are placed at convenient points. It is necessary to place coal and other supplies at each steam-shovel level and bring the equipment to the machine shop at more or less frequent intervals.

BEGINNING OPEN-CUT WORK IN BINGHAM CANYON.

The surface of the orebody is irregular, so that in the removal of the capping there are times when thousands of tons of ore are loaded. These are some of the important factors that went toward deciding on railroad connections to the different steam-shovel levels. It certainly makes the most flexible arrangement to be had. Owing to experience with the steep-grade, heavy-curvature railroad, and our own experience during the first operations, it was decided to build these permanent tracks on 1%, compensated grades and 16° maximum curves, with as few of the heavier curves as possible. These are the tracks that are in course of construction now to the upper levels on the Carr Fork side of the property. I wish to make a comparison now of the handling of ore over the new lines with the old lines. The new way, the saddle-tank locomotive is used with a crew, all cheap labor. This locomotive handles 240 tons of ore at ten miles per hour over these grades. The old way was to use Shay engines, the crew all expensive labor, handling 150 tons at five miles per hour. You can draw your own conclusions. The steam-shovel benches are at a maximum of 75 ft. high. These levels extend from the main level A at elevation 6340, in alphabetical order to letter U. Each level is connected into this system of railroads so that coal and other supplies can be delivered to each steam-shovel level, and ore removed from these levels whenever met.

There are four ways of breaking the rock employed at the steam-shovels; the gopher method; keystone holes; toe-holes; and pot-holes. Where there is plenty of room a gopher-hole is driven into the face of the level for 40 or 50 ft., and a T driven, making two pots for the powder. Then a sufficient amount is put in to break the rock. This method breaks the largest amount of material. The keystones are used to strip the ore and also to break the rock where the room is limited. The toe-holes are driven along the base of the level, keeping it in good line and allowing the steam-shovels to work closer to the bench. The pot-holes are for breaking loose rock off the face of levels, and aiding in the stripping of the ore. In addition to this, gangs of men are constantly employed breaking down the loose rock that does not come freely. This work saves a lot of labor and expense, as sometimes a very small rock keys up thousands of tons of rock above it. Black powder (FF) and 60% Monobel is used on this work. The present equipment used in steam-shovel operations at the Utah Copper mine is as follows: 25 steam-shovels, 53 locomotives, and 408 cars, which are moving approximately three-quarters of a million yards of material per month.

The Bingham & Garfield railway, extending from the Bingham district to the mills and smelters at Garfield, was first planned during 1908. Construction work started in April 1910, and completed in April 1911. This railroad is a low-grade line, having 2½% compensated grades and 8° maximum curves, with the exception of the Dry Fork crossing, where two 10° curves are used. The Mallet type of locomotive is used for the freight service, and hauls forty empty ore-cars up the grade at twelve miles per hour. These cars are all 60-ton capacity, making 2400 tons of ore moved each trip. The characteristics of construction on this line were the three large steel viaducts crossing Carr fork, Markham, and Dry fork, and 4800 ft. of tunnels. There was an enormous amount of work done during the thirteen months required to complete this line. In that time 1,780,000 cu. yd. of material was handled; 12,000 cu. yd. of concrete was placed; 1400 lineal feet of drain tunnel was built; 4800 lineal feet of tunnel was driven; Carr fork bridge, 680 ft. long, 182 ft. high; Markham bridge, 640 ft. long, 225 ft. high; Dry fork bridge, 670 ft. long, 188 ft. high, were built. One mile of this road cost over half a million dollars.

Bingham canyon now has better railroad facilities than any other mining district I know of. This system of roads will accommodate any probable future development, has ample capacity to handle the tonnage, and can assure all the mines of steady handling of the product of the future.

Plymouth Consolidated Mine

By An Occasional Correspondent

A mining operation that will be watched with considerable interest is the reopening of the old Plymouth Consolidated mine in Amador county by an English company, as mentioned in the *Mining and Scientific Press* of October 21. This mine has been idle since October 1892, after a number of successful years, during which time it was one of the largest producers in the State.

The Plymouth Consolidated was a consolidation of the Empire, Amador, Pacific, and Plymouth companies formed in 1883. The mines were all well developed and had produced, according to reports at that time, in the neighborhood of $2,500,000. Since then the mine produced over $4,000,000, and the property therefore can be credited with a total production approximating $6,500,000.

The property was worked continuously until 1888, when a fire occurred in the mine, breaking out between the Pacific and South Empire shafts, in which considerable damage was done, and work was not resumed for some months. The fire was extinguished only after sealing up the mouths of all the shafts. A short description of the property may be of interest.

The vein was from 40 to 70 ft. wide and dipped to the east about 57°. The main ore-shoot consisted of a body of ribbon quartz 30 to 50 ft. wide and about 400 ft. long. The mine was opened by four shafts, three following the vein on the incline, and one, the Pacific, a 3-compartment vertical shaft 1700 ft. deep. The main shaft was equipped with self-dumping skips of 1½ tons capacity. The mine was comparatively dry, and buckets were used for baling, hoisting about 18,000 gal. daily.

The property was equipped with two 80-stamp mills, one having 750-lb. stamps, the other 1000-lb. stamps. Water was used for power, there being 23 wheels in all on the property, of which three were turbine wheels used at an approximate head of 80 ft., and the others Pelton, Knight, and Donnelly wheels at a head of about 550 ft. The mill had a capacity of about 300 tons per day, and in 1887, though hampered at times from shortness of water, crushed 97,000 tons.

The concentrate averaged from 1¼ to 1½%, and was currently supposed to average in excess of $100 per ton. It was treated at the company's chlorination works at a stated cost, inclusive of all charges and proportion of general expenses, of $13.40 per ton of concentrate.

The average yield from ore in 1886 was $6.18 per ton, and in 1887 $7.59 per ton, the cost of production being given as follows:

Mining	$2.34
Milling	0.39
Concentrate expense	0.17
General expense	0.17
Total	$3.07

After the fire the shaft was found intact, but a number of cave-ins had occurred throughout the mine. Considerable development and exploratory work was done in various places and 40 stamps kept running during a part of 1889 and 1890, but in 1891 only 10 stamps were run and then only a part of the year, starting in April and closing down in October. The following from the ninth annual report of the company may be of interest, showing that dividends of $2,280,000 were paid during the nine years following the consolidation:

Cash on hand at time of organization, Jan. 1883		$ 153,320
Production to January 1, 1891	$4,045,983	
Production for 1891	19,775	
Total production	$4,065,758	
Miscellaneous receipts	5,667	
		$4,071,425
Total cash received		$4,224,745
Operating expenses	$1,723,337	
Construction	217,682	
57 dividends paid	2,280,000	
		$4,221,019

It is understood that final arrangements for the sale have been completed and the property has now changed hands. The results of systematic development by the new company will be of much interest.

Copper Producers' Association Statement

The Copper Producers' Association October statement shows a decrease during the month in accumulation in this country of 5,897,214 lb. The details are as follows:

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States October 1, 1911	140,894,856
Production of marketable copper in the United States from all domestic and foreign sources during October	118,255,442
Deliveries of marketable copper for consumption and export during October	124,152,656
Stock of marketable copper of all kinds on hand and at all points in the United States November 1	134,997,642

The changes in surplus since January 1, 1911, have been as follows, in pounds:

	Increase.	Decrease.
January	20,409,295	....
February	14,198,280	....
March	5,370,164	....
April	3,547,974	....
May	440,024	....
June	....	8,561,768
July	....	19,695,306
August	....	4,297,357
September	7,453,355	....
October	....	5,897,214

L. Vogelstein & Co. give the following figures of German consumption of foreign copper for the months January to September, 1911:

Imports of copper, 143,203 tons; exports of copper, 6610 tons; consumption, 136,593 tons, as compared with consumption during the same period in 1910 of 122,503 tons. Of the above quantity, 125,649 tons were imported from the United States.

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Surface Indications of Ore-Shoots in Depth

The Editor:

Sir—In your issue of October 28 Mr. H. C. Cutler contributes another interesting chapter to the discussion of the relation of ore-shoots to gulches and depressions which may cross the strike of a vein. I regret, however, that Mr. Cutler, like several others who have been good enough to enter into this discussion, seems to have misunderstood my original statement, which I have several times repeated, to the effect that my observations refer to the condition at the surface and near it only, and not to those found in depth. I have not, in any of my own contributions to this subject, offered any explanation for the occurrence of the phenomena described, but have contented myself with a description of conditions as I have found them. In the issue of the *Mining and Scientific Press* of May 29, 1911, Mr. F. L. Ransome described in considerable detail the various causes of gulches and depressions, and I agree fully with his conclusions as to the various causes of such topographical inequalities of the surface, but I will once more endeavor to make my meaning clear, and to this end it seems essential that I do so graphically; therefore the accompanying sketches. Fig. 1 illustrates a longitudinal section in the plane of a vein, in which occurs an ore-shoot that outcrops on the hillside in the vicinity of a gulch. The ore-shoot, in its downward trend along the plane of the vein, *passes beneath the gulch*, but the outcrop of the ore does not—it stops upon reaching the gulch.

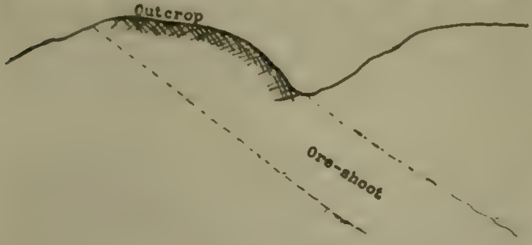


FIG. 1.

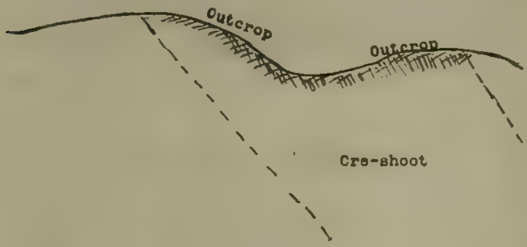

FIG. 2.

Fig. 2 is also illustrative of a longitudinal section of a vein in which an ore-shoot occurs at the surface and *does cross* the gulch. This is the condition that I maintain rarely occurs, particularly in schistose and slaty rocks. For the good of the cause, and also to please those who entertain opinions adverse to my own concerning this matter, I will say that since my last contribution on this subject I visited the Mariposa mine at the town of Mariposa, California, and there found that the vein at the surface—ore-shoots and all—crosses the gulches which intersect it, entirely regardless of my theory and with small respect for my opinion. However, the Mariposa vein occurs in an extremely hard, massive, diabase-porphyrite, and it seems that veins occurring in massive rocks of this description do not always conform to 'the rule,' although I know of numerous instances where the reverse is the case in massive granite, in rhyolite, in quartz porphyry, and in other massive rocks, these instances being no exception to the conditions which have been referred to by me as most commonly occurring.

I hope I have succeeded in making my position more clear. Even the illustration accompanying Mr. Cutler's contribution is in accordance with the views expressed in my original and subsequent contributions to this subject. The vein, on its downward trend, passes on beneath the gulch, but the outcrop of the ore-shoot appears on one side of the depression only. This is 'according to Hoyle.'

WILLIAM H. STORMS.

Berkeley, California, October 30.

Gasoline From Natural Gas

The Editor:

Sir—Your editorial of October 28, urging your readers to comment upon articles appearing from week to week is well taken, and has encouraged me to somewhat criticize your 'Concentrate' of October 21, wherein you state that although it is not impossible to make gasoline by compressing and cooling natural gas, it is not probable.

We have in the Buena Vista hills, Kern county, California, the greatest gas belt in the world, and from this gas, by means of a commercial process consisting of compression and cooling, a gasoline, or more truly a naphtha, has been produced—one thousand feet of gas yielding five quarts of this naphtha. A complete gasoline-making plant has been set up by the Honolulu Oil Co., which will, no doubt, manufacture gasoline from natural gas, if it does not first sell out to the Standard Oil Co. In the Fullerton region gasoline and naphtha are also being extracted from natural gas, and for a considerable time gasoline has been manufactured from natural gas in the Eastern fields.

This product of so-called gasoline is of very high gravity, and is so volatile that it is unsafe to transport and is ruinous to an engine using it. The Eastern States have legislated against its transportation by the railroads. It is, however, capable of being reduced to a normal gravity gasoline by topping it, and this, in fact, is done; the lighter products are eliminated and the residuum is merchantable gasoline.

WILLIAM R. JEWELL.

Bakersfield, California.

[Our 'Concentrate' was intended to prevent too hasty belief in too extensive claims for the new process. As Mr. Jewell states, the resulting product is not a true gasoline, but a naphtha from which a certain quantity of gasoline may be obtained. And a definite statement of the cost of production would be of great value.—EDITOR.]

NEARLY a third of a billion dollars was added to the wealth of the United States from the mineral production of the Western States during 1910, according to the figures of the U. S. Geological Survey. This includes about $66,000,000 worth of coal, the remaining production, principally metals, having a value of practically a quarter of a billion dollars. The total figures of Western mineral production as compiled by the Survey are $313,944,881. This is about one-fourth the total agricultural production of the same area, the proportion between mineral and agricultural production being about the same as for the entire United States. The agricultural production of the Western States, derived from figures of the Department of Agriculture, was approximately $1,394,791,000. The area considered includes the belt from the Dakotas south to Texas and the territory westward.

IN SOME PARTS of California it is necessary to store enough water to provide for the consumption for a period of from 5 to 7 successive dry years. The run-off generally exists from January to May, and the stream beds are dry for the remainder of the year.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

OLD VARNISH may be removed from a metal surface by dipping it in equal parts of ammonia and 95% alcohol.

CARBONADO is a black variety of diamond which is without cleavage. It is therefore useful in drilling, and commands a high price.

GUANO DEPOSITS, when occurring in caves, would presumably be subject to location as placers, following the ordinary procedure as to annual labor and patent.

TO TIGHTEN a screw-cap, put it over the end of a round stick and, with a nail or centre punch, make small dents in the thread about $\frac{1}{4}$ in. apart. This makes the thread deeper and will usually hold very well.

CUPRITE may be occasionally confused with hematite, as both are often the result of oxidation of sulphide minerals. They may be distinguished by the difference in the color of the streak and by simple blow-pipe tests.

NATIVE COPPER is not objectionable in copper smelting operations, and the presence of native copper in sulphide ores does not decrease their selling value. Copper smelters situated near large cities often buy scrap copper to add to the smelting charge.

TO GLUE ASBESTOS to iron, use silicate of soda. Brush the glue on the metal and then stick on the asbestos fibre, using the asbestos freely. This glue will withstand the heat and hold the asbestos firmly in place. It can usually be obtained from druggists and always from dealers in asbestos.

SATISFACTORY prints can be obtained from cracked negatives, if the film is not injured. Place in the frame carefully and cover with tissue paper or ground glass to diffuse the light as much as possible. Rotating the frame during the printing operation is also beneficial. By making prints in this way the cracks will hardly be perceptible.

NICCOLITE is a massive mineral of a copper-red color, sometimes with a white metallic crust. It has the composition NiAs (Ni 43.9%). On charcoal it gives off arsenic fumes, but the reaction for nickel in the borax bead is usually obscured by the presence of a small amount of cobalt. It is soluble in nitric acid, and the ordinary qualitative tests for nickel may be made on this solution.

BITUMINOUS COAL of which the content of volatile combustible matter is too high is not satisfactory for use in the boilers now in service in the Navy, because it produces too high temperature in the uptake and an excessive amount of soot, but such coal is used by steamships whose requirements are not so exacting as those of the Navy, by railroads, and for domestic and commercial purposes.

A SERVICEABLE chuck for holding drills and small work can be made from an old brace. With a hacksaw cut the chuck off the brace, leaving almost two inches of the rod on the chuck. The rod portion is then heated, straightened out, and turned up true. Then drill an old lathe centre to receive the rod portion and drive the chuck in. Drill a small hole for a spanner wrench, and the chuck is complete.

COPPER MINERALS are objectionable in cyanidation, because they consume cyanide, and the copper which goes into solution interferes with precipitation of the gold by means of zinc. The use of ammonium salts has been recommended to prevent this, but has not received wide application as yet. In some cases the cheapest method of treatment for ores containing copper is the use of cyanide, but some method of precipitation not involving the use of zinc should then be employed.

A DAMP-PROOF COATING for walls is made in the following manner. Dissolve 30 parts tin in 40 parts hydrochloric acid and add 30 parts sal ammoniac. Prepare a powder of 60 parts freestone, 20 parts zinc oxide, 15 parts powdered glass, 10 parts powdered marble, and 5 parts calcined magnesia. Make the powder into a paste with the liquid first prepared. Add coloring matter if desired. This composition may also be used for repairing stone work.

PIPES supplying air to rock-drills should be of a size to permit the passage of air at a velocity not greater than 25 to 30 ft. per second, while all bends and angles (especially short ones) should be avoided, as they add greatly to the friction of the air, and thus decrease the pressure. The friction of the air is proportional directly to the length of the pipe, and to the square of its velocity. For this service, pipes up to 5 in. diam. are provided with couplings; above that, with flanged joints made up with gaskets. Great care must be taken that these joints are perfectly tight, as the loss, even from a pin-hole, is considerable.

IN DEVELOPING the water of a particular stream the first necessity is to know how much water must be provided for—the volume that descends in the channel from day to day and from month to month. This necessity has its counterpart in the ordinary conduct of business. Every business man recognizes the necessity for taking account of stock. Every bank is required to keep an accurate record of its resources. There is no difference in principle between these operations and taking an inventory of water resources. To handle and develop them properly it is necessary to keep an account of stock.

A CLAIM larger than that allowed by the statutes is not void, except in case of fraud or a mistake of the grossest kind that presumes fraud. Where the purpose was to make the claim of the statutory size and the error occurred inadvertently, the claim is only invalid to the extent of the excess. In the case of a location notice calling for a stated number of feet in each direction from the discovery or location stake, the bounds of the valid claim can easily be determined by measuring off the required distance in both directions along the lode line, and undoubtedly the locator can be held to his description, though in the absence of protests and adverse claimants he can elect where the excess shall be deducted. Where the claim is not laid out from a specified point, the locator will have the right in all ordinary cases to say from which part of the claim the excess may be deducted.

ONLY public domain is open to mineral location, and there are parts even of it that are not open to location, though it is not necessarily true that only unoccupied unclaimed public land can be located as mining claims. It is the policy of the Government that the public land should be put to its most useful purpose, and in accordance with this policy, the Land Department will receive a protest, and, under proper conditions and satisfactory representations, will undertake to determine for what purpose the land is most valuable, and will render judgment accordingly, up to the time the land leaves its jurisdiction by the issuing of patent, or until by some specific act of congressional or presidential legislation, the land is removed from its jurisdiction. However, the Land Department will not undertake any determination of the rights of rival claimants under different classes of possession or entry, until patent is asked for the land in question, except in flagrant cases of its being occupied in bad faith to the detriment of good public policy and the exclusion of *bona fide* locators and entrymen.

Encouraging Outlook at Mexico Mines of El Oro.—Increase Shown in Value of Year's Production.—Larger Ore Reserve.—European Interest in Imbert Process of Slime Treatment.

It will be remembered that about a year ago the affairs of the Mexico Mines of El Oro assumed an unpleasant complexion owing to the French shareholders and the Pearson interests becoming restive at the conservative policy of the controllers, the Exploration Company. This is all past history, and it is not necessary to revive memories of unfortunate personal disputes. Suffice it to say that the Exploration Company, being in the minority, had to resign control and management. Fergus Allan succeeded A. F. Main as manager and André P. Griffiths was appointed consulting engineer. The unfulfilment so far of the gloomy views expressed by R. T. Bayliss, the chairman, and by Mr. Main, as to the future of the mine, is noteworthy. In September of last year Mr. Bayliss uttered a solemn note of warning to shareholders advising them to expect a decrease in the value of the ore, and in December a circular announced that the reserves were not being increased to keep pace with the mill. It also was stated that the output would have to be reduced owing to the necessity for retimbering the South shaft, and the unpreparedness of the new North shaft for handling the required amount of ore. It must be a pleasant surprise, therefore, to find that these prophecies of disaster have not yet come true, and that both the performance of the mine and the views of Mr. Griffiths put a more cheerful complexion on affairs. For instance, the amount of ore crushed during the year ended June 30 last was practically the same as during the previous 12 months, the figure being 136,408 tons, and the yield was gold-silver bullion worth $1,528,229, as compared with $1,392,336 a year ago; and in spite of large expenditure on retimbering, it was possible to distribute £144,000 as dividend, being at the rate of 80% on the capital, as compared with £126,000 the year before. Similarly, the ore reserve, instead of falling, has increased, and stood at 318,720 tons on June 30, as compared with 283,735 tons a year ago, the average content being practically the same at 9½ dwt. gold and 6 oz. silver. The retimbering of the South shaft and the sinking of the North shaft have been carried on so rapidly that little or no inconvenience was caused in hoisting. Mr. Griffiths has just returned from the mine and has issued a lengthy and interesting report.

MEXICO MINES OF EL ORO.

A few weeks ago I sent you some information about the Trollhättan electric furnace in Sweden that is being used for treating zinc-lead sulphides, and I reported that an English company had been formed, called the Hydraulic Power & Smelting Co., to acquire the rights and expand the operations. Since writing, *The Mining Magazine* has published a critical survey of the finance and technology of the electric zinc industry, in connection with this particular furnace. Many of the firms who furnished money for the test were not sufficiently satisfied with the results, and the Sulphide Corporation is the only Australian company that is sending its slime to be treated at Trollhattan. In the meantime these firms have been making investigations into the Imbert process as adapted by F. A. J. Fitzgerald of Niagara Falls, and in all probability something more will be heard of it before long. Mr. Fitzgerald read a paper on his invention at the celebration of the fiftieth anniversary of the Massachusetts Institute of Technology in the spring. At the time few of the technical papers appreciated the importance of this furnace, and the paper attracted little attention. The Imbert process is a modification of the old reaction whereby molten iron takes the sulphur from zinc or lead sulphide; his invention consisting of a special bath in which the reaction can be effected rapidly and continuously and at a comparatively low temperature. His difficulty was a mechanical one, and the Hohenlohe Hütte in Germany, where the process was being tested, invited Mr. Fitzgerald to come over and advise as to the application of electric heating. One of the obstructions in the path of the electro-metallurgist is the enormous wear of electrodes. Mr. Fitzgerald discarded arcs and electrodes in contact with the charge, and designed a 'resistor' in the form of an arch immediately above the surface of the charge. The heat is transferred by radiation, and the wear and tear of the resistor is accordingly small. Mr. Fitzgerald found that the loss of heat with this resistor was too great for success. Another method has since been adopted, but no definite information as to the substitute is at hand.

In the process the zinc is distilled, the lead and silver falls to the bottom, and pyritic material forms a matte. Mr. Fitzgerald has not told us much about the working of the process, but before long something will be published. E. Gibbon Spilsbury examined it some time ago. One advantage of the process is that no roasting is required. This is of importance not only on account of the elimination of an expense, but because losses of silver by volatilization are avoided. The furnace, like others used in beneficiating zinc ores, will not successfully treat ores containing much gangue, so that if the slime material is of such a quality it must be first concentrated by means of a flotation process. It is remarkable to find how many old and silent mines with finely mixed complex ores have sprung into life again since the electric smelting methods have come forward. For instance, the mountains of massive fine-grained sulphides from New South Wales, Newfoundland, and elsewhere are now once more attracting attention. There is, I believe, a large amount of these sulphides in the United States, especially in Colorado. They will all be benefited one day by flotation and electric smelting, but the time is not yet.

From time to time I have recorded various incidents in connection with the development of the Ferrobamba copper deposits situated in the department of Apurimac, Peru. The reports by W. E. G. Firebrace and Claude Vautin were so glowing as to the immense possibilities that few people in England believed them, and eventually, in order to obtain adequate capital, A. C. Burrage, of the Amalgamated Copper, was approached. He bought shares and took an option enabling him to acquire the property and float an American company for its development. This scheme was not carried through, and subsequently he proposed to acquire a lease on the property and work it at a small royalty. This proposition was rejected by the shareholders. In the meantime he has been purchasing shares privately, from all sources, and at the present time he is practically in control. As further capital is required, the shareholders have agreed to issue 60,000 new shares of 10s. each to rank equally with the existing 120,000 shares of £1 each and entitling the holders to receive all the profit up to 15s. per share. Mr. Burrage is also a creditor to the company for several thousand pounds advanced, and this will be repaid out of the new issue. There are so many ins and outs in connection with the finance of this company, that an outsider finds it impossible to follow all the history. Nevertheless, the deposit and its development will have interest technologically.

JOHANNESBURG, TRANSVAAL

Individual Power Plants Growing in Popularity.—Increase in Gold Output. Decrease in Coal Production. Government Investigation of East Rand Proprietary Mines.

It can scarcely be said that the Victoria Falls & Transvaal Power Co. has come up to expectation, with its undertaking formed for the object of supplying the gold mines on the Rand with electric power and compressed air for mining purposes. Quite apart from the initial difficulties attending such an ambitious scheme, there are many which might and ought to have been avoided. From the outset the restrictions placed upon the company in connection with the raising of the necessary capital have not tended to smooth working, for had it been free to purchase its plant in the open market, instead of being compelled, for the most part, to go to Germany, it is possible that a far more reliable and cheaper equipment could have been secured. There have been mishaps, such as, for instance, disasters at sea, for which the company cannot be held responsible, but it is anything but pleasant for the mines, **having once changed over from steam to electricity, to** find that the power company cannot supply the necessary power. There was no alternative but to revert to steam in many instances, and in others where the whole plant had been arranged to be electrically driven, a steam plant as a standby became imperatively necessary. It may be that only in a few instances has this backwardness of the power company resulted in any serious loss of output, but it has caused many inconveniences, and indeed not a little surprise, because it is generally admitted that the Rand offers, with its compactness and natural facilities, an ideal field for the use of electrical power. It has long been contended on the Rand, by electrical engineers, that despite its suitability as a field for large-scale power operations, individual properties can generate their power quite as cheaply as they can purchase it from the Victoria Falls power company. Instances of this may be seen at Randfontein, where the cost is only about half of that charged by the power company, and at Kleinfontein, where a new station has produced power at the power company's ordinary charge, although only one-fourth of the plant is at work. The load factor is such that the cost of the power (0.75 of a penny per unit) must be at its maximum. With such striking successes as those achieved at Randfontein, East Rand Proprietary Mines, and Kleinfontein, in the face of the many disappointments suffered by its customers at the hands of the power company, it is not at all unlikely that in the future more individual concerns will establish their own power stations.

The total mineral output of the Transvaal, excluding diamonds, for the 3 months ending with August, according to the report of the Mines Department, is as follows:

Gold:	June.	July.	August.
Rand	£2,795,550	£2,892,974	£2,899,725
Other districts	116,934	129,930	130,813
Total	£2,912,484	£3,022,904	£3,030,538
Coal	87,845	93,029	90,144
Tin ore	34,971	45,009	24,833
Lime	11,091	11,983	12,562
Silver	8,055	8,416	8,189
Copper ore	8,718	5,567	5,907
Flint	1,120	613	1,504
Magnesite	75	....	50
Miscellaneous	167	79	190
Total	£3,064,526	£3,187,600	£3,173,917

It will be seen that, despite the increase in the gold output, the total mineral output declined in value during the month of August, principally through a fall in the shipments of tin ore. This, however, is only temporary; actual **shipments, not output, being taken into consideration.** Coal also declined in tonnage and value. The average selling price for August was only 4s. 7.79d. per ton, the lowest recorded price yet attained for the whole of the collieries in the Transvaal. The nine collieries situated outside the two leading coal districts of Springs and Middelburg fared even worse, attaining an average selling price of only 4s. 2d. per ton, the average selling price for Middelburg being, however, 4s. 6d. per ton. This is a striking result, when it is borne in mind that every producing colliery of importance is in the Transvaal Coalowners' Association.

One of the principal mining topics of interest has been the announcement to the effect that the Government has seen fit to appoint a commission to investigate the alleged loss of gold at the East Rand Proprietary Mines and at the same time to enquire into the circumstances surrounding the serious depreciation in the market value of the **company's shares. The resident magistrate of Johannesburg,** H. O. Buckle, has been appointed as chairman, and Ross Frames, of the Premier Diamond mine, and the government mining engineer, constitute the other members of this interesting commission.

BUTTE, MONTANA

October Production of District 21,400,000 lb.—Anaconda to Resume Producing in December.—Kennedy Creek G. M. Co. Starts Operating.

The production of the district for the past month does not differ much from that of the previous month, when **the output was 21,400,000 lb., including all the producing** properties in the district except the East Butte company. During October the Washoe smelter turned out 16,000,000 lb. and the Great Falls smelter 5,400,000, making a total of 21,400,000 lb. **In this is included the Tuolumne production** of about 500,000 lb. and the North Butte output of 2,100,000 lb. The East Butte is not included in the above figures; the production of that company amounted to about **900,000 lb. The Anaconda company is working its properties** well within the curtailment agreement, and according to present calculations the production for November and December will be about the same as October.

It is expected that the Anaconda mine will take its place among the producing properties again about the first of **December, after having been closed down for slightly over** one year. In that time the shaft has been retimbered from the 800-ft. level to the lowest level, which is the 2400-ft. Three years ago the Anaconda was closed down in consequence of a fire in the St. Lawrence, the gas and smoke having worked its way through to the different levels of the Anaconda. While shut down the shaft was retimbered from the surface to the 800-ft. level, and mining was resumed in September 1909. Last October, one year ago, **there was another shut-down, and the remainder of the** shaft was retimbered. The starting up of the Anaconda does not indicate any increase in production, for some of the other mines will be closed down for repairs just as soon as the Anaconda starts up. According to present arrangements, the mine will be one of the last to be equipped for hoisting ore by the compressed-air system.

The Kennedy Creek Gold M. Co., which was organized seven years ago to develop placer property in Missoula county, and which over one year ago passed into the hands of San Francisco capitalists on a 15-year lease, has started operations. Last April work was started on a dredge. A few days ago this dredge, built by the Risdon Iron Works of San Francisco, commenced operations. It has a capacity of 75,000 cu. yd. of gravel per month and is constructed to dig to a depth of 30 ft. As the average sounding on the 200 acres of property gives 28 ft. as the maximum depth through to bedrock, the dredge will answer all purposes. It is being **worked day and night, and the results** are satisfactory at the outset. There are 34 buckets, having a capacity of 5½ cu. ft. There is a bountiful supply of water at hand and all the wood required to operate the dredge. Tests made of the ground show the gold content of the deposits ranges from 20c. per cubic yard near the surface to about $5 per cubic yard at the bottom of the gravel. From the data obtained in tests, after reasonable allowance is made for boulders, which in the lower part of the section constitute about 10% of the material, the deposit in the southern part of the basin seems to contain on the average about 80c. per cubic yard, including everything from the surface down to bedrock, or about $4 per bedrock yard.

W. A. Clark has not yet reached any conclusion as to his plans for the future in regard to finding a concentrator for the treatment of the zinc ore from his Elm Orlu mine. It seems certain that the Anaconda company will not rebuild the concentrator building destroyed some two weeks ago, as Mr. Clark's lease on the mill expires in June, and the company would not have any use for it. What seems the probable outcome is the erection of a concentrator by Mr. Clark on the ground which he has selected for the building of the zinc smelter, but even if he does decide on this course, before the material can be secured and the machinery erected, the winter will be well advanced, and little if any work can be accomplished before spring. The ore-bins at the Elm Orlu mine are full, and, so far as hoisting ore is concerned, all work has been stopped, the men being informed that the shut-down is indefinite.

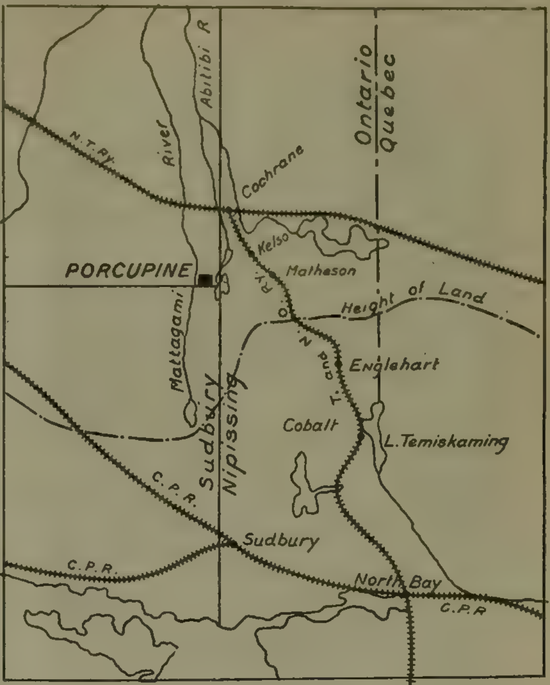
TORONTO, CANADA

Close of Navigation Approaching.—Dome Mine Visited by Stockholders.—Mine Developments.—Report on West Shining Tree.—Other Notes.

The close of navigation is rapidly approaching in the Porcupine district, where some severe frosts already have been experienced, and during the month or so which usually intervenes between the suspension of traffic by boat and the freezing of the lakes sufficiently to allow teaming over the ice, communication will be much interrupted. Recent heavy rains have resulted in a deluge of surface water, which has seriously interfered with operations in some of the mines, and managers find much difficulty in keeping the shafts dry. The double-compartment permanent shafts are now made with cement collars in order to prevent flooding.

The Dome mine was visited October 25 by a large party of the directors and stockholders, principally from the United States, including many men of prominence in financial and industrial circles. Ambrose Monell, managing director, pointed out that diamond-drill work over an area of 1000 ft. had considerably improved the condition of the property. They had positive proof of good ore to depth, the golden sidewalk vein having been cut at 200 ft., although the drilling showed a wide variation in ore content. Provided sufficient labor can be secured for the completion of the mill, it is hoped to have the plant in running order by the new year. At the Dome Extension the main shaft is down 115 ft. It is proposed to sink several hundred feet and cut the anchor vein to the south at each 100 ft. down. A new discovery has been made about 500 ft. from the shaft, consisting of a vein of quartz-porphyry 8 ft. wide. The Foley-O'Brien company is sinking a shaft about 140 ft. from the southern boundary and has reached a depth of 70 ft. A number of small veins of good ore have been found. On the East Dome a porphyry dike has been found containing many quartz stringers in which free gold appears. The shaft being put down on the Davidson claim of the Crown Chartered reached the 100-ft. level on October 15. At the American Goldfields a depth of 70 ft. has been reached in the shaft and a hill has been tunneled for 80 ft. A quantity of rich ore has been taken out. Charles E. Watson has resigned as manager of the Dobie and Tisdale companies to assume the management of the Plenaurum and Armstrong-Booth properties. He is succeeded by George E. Farish, who has a wide American experience. The first vein of the Miller-Middleton, adjoining the Hollinger, has been tapped by a cross-cut at the 75-ft. level. It is from 3 to 4 ft. wide on the surface and maintains its width where cut.

A report has been made to the Ontario Department of Mines by R. B. Stewart, of Toronto University, of an investigation of the new goldfield of West Shining Tree. This includes the townships of Asquith, MacMurchy, Churchill, and Fawcett, lying around West Shining Tree lake, about 70 miles north of Sudbury. Mr. Stewart describes the country as level, with no prominent elevations and few rock exposures except where it has been swept by fire. The geology is rather complex, the formation where the claims are situated being of Keewatin age. The discoveries for the most part are situated on zones of weathered schist, containing veins and stringers of quartz that generally conform to the strike and dip of the schist. The quartz widens in places to several feet, but does not carry this width far till it breaks up into stringers or disappears. Thirteen locations were visited, on several of which free gold was seen in place. The property known as Gosselin's, which has attracted most attention, showed apparently a very large body of quartz with free gold in several places. Seven samples of quartz were collected from properties on which no gold was seen. The results of assays of these showed that six of them were worth from 40c. to $6 per ton.



PART OF ONTARIO.

The statement of the Nipissing for October 2 shows ready assets of $459,000 on hand after the payment of the dividend. The treatment of high-grade ore by the Butters plant having been successful, experiments are now being conducted to test whether by some slight alteration in the process the large amount of low-grade ore accumulated by the company cannot be treated by this system. Should the results be satisfactory a 200-ton mill will be erected for the purpose. At the annual meeting of the Little Nipissing held here October 25, the shareholders authorized the issue of 500,000 shares of preferred stock bearing cumulative dividends of 2% per annum. This will be offered to shareholders at 20c. per share, redeemable in five years at 40c. per share, together with any dividends remaining unpaid. At the Drummond a vein of rich ore averaging 1½ in. wide has been found on the surface, paralleled by a wider calcite vein with good silver content. The annual statement of the City of Cobalt shows a production of 292,694 oz. of silver from 392 tons of ore. The ore developed on October 1 was estimated at 181,650 oz. valued at about $95,366. The cash in bank amounted to $31,954 in addition to ore at smelter valued at $26,860.

J. H. Plummer, president of the Dominion Steel Corporation, in speaking at a banquet given by the city council of Sydney, Nova Scotia, to the directors last week predicted an increase in the finished steel output from 220,000 to 400,000 tons per annum. He said that according to their present plans the corporation before long would control 20 collieries, a number not exceeded, so far as he knew, by any company in England or in Canada.

NEW YORK

STEEL PROSECUTION DAZES WALL STREET.—POSSIBILITY OF ATTACK ON SMELTER TRUST DISCUSSED.—CACTUS BUYS COMBINATION KEATING.—GIROUX PLANS ANNOUNCED.

As may readily be surmised, the recent action of the Government attacking the United States Steel Corporation has been the principal and by far the most important factor for the week and the main topic of discussion among those who hang over the Wall Street tickers. There are in Wall Street probably more varying opinions regarding the present situation than there are anywhere else in the country. The lack of cohesion in the market to give a decided trend to the course of trading has put many of the older and more experienced heads into something of a daze. The Street has played politics for many years, but never from its present position. The Eastern financial centres have small use for the iconoclast, and there are many who walk daily in the shadow of Trinity Church that proclaim this to be the day of the iconoclast and no time for the old staid citizen to expect any consideration.

There has been a good deal of discussion concerning the possibility of an attack upon the smelter trust. American Smelting & Refining has at several times during the past few days been under strong selling pressure, from which it rallied in a rather half-hearted way when an official statement was given out that no suit had been begun as yet by the Federal law department. That the smelter trust has been among those under close scrutiny by the Government is not to be doubted, and if some of the smaller independent operators throughout the West were to be allowed to conduct the investigation and sentence the offender, the result would never be for one moment in doubt.

The smelter trust, as the term is used, includes the American Smelting & Refining Co., the Smelters Securities Co., the Guggenheim Exploration Co., and in turn the chain of porphyry coppers which have been the controlling factor in the copper world for the past two years. The copper mines that are allied directly with the Guggenheim interests include Utah Copper, Nevada Consolidated, Ray Consolidated, Chino, Braden, the Alaska properties, and others of less note. The holdings in copper which the Guggenheims have built up within the last few years, comparatively speaking, will soon give them first place as sellers of copper. Holders of the Guggenheim shares in one enterprise or another are scattered all over the world. Chino is largely held in France, as is Ray Consolidated, and a movement is on foot now to list both on the Parquet department of the Paris Bourse. Braden is about to be listed on the New York Stock Exchange, on the strength of which the shares have been pushed upward and have enjoyed a strong market recently. The entire copper list has been something of a mystery, the movement in Braden could perhaps be accounted for as a move preparatory to forsaking the outside market and going indoors, but all of the copper shares have apparently been stronger than conditions in the metal market would seem to justify. The statement is not infrequent with owners of large plants that the present volume of business is not sufficient to pay expenses, which is only quoted to show that there is something more in the copper situation than mere unwillingness to stock up in the face of increasing production. The latter being an argument much used by would-be bulls in the metal market.

The Cactus Copper Co., which at one time was looked upon as a low-grade milling copper of great promise, but which was very unfortunate in being unable to develop any body of commercial ore on the ground near Globe, Arizona, where its first development was undertaken, is to make an effort to save something for the shareholders. The Cactus company will acquire the Combination Keating near Radersburg, Montana, on a stock basis, using the reserve in the treasury of the Cactus for development purposes. The new property is a gold producer of some promise and it is hoped to win back the original investment for the holders of the Cactus. N. L. Amster has finally severed his connection with Arizona Commercial, and Charles Sumner Smith, president of the Old Dominion has taken up the management of the reorganized company.

George Martin Luther, president of the Granby Consolidated, says that the Granby will be in operation again by the first of the year. The coal strike in British Columbia has finally been settled, but it will take sixty days to get fuel supplies on hand and the idle furnaces blown in. Mr. Luther, who is also general manager for the Nichols Copper company, says the Granby can make $50,000 net on the present metal market when again operating at capacity. The Nichols Copper Co. operates one of the largest refineries in the country at Laurel Hill, on Lond Island, and handles a great deal of copper ore for Phelps, Dodge & Co.

The Giroux management has at length broken silence. T. F. Cole, the president, in a recent interview unfolds plans for increasing the capacity of the concentrator to 1000 tons and says that the supply of concentrating ore already blocked out and demonstrated in the underground workings on the sulphide zone is amply sufficient to keep the proposed plant in steady operation for many years to come and in the meantime new orebodies of the same nature will be developed in various sections of the company's vast mineral estate. Giroux shareholders will be glad to know that they are to have a plant and that it will be kept going for years to come, but they would doubtless relish a more definite statement. Giroux has been one of the mysteries of the copper list. Many mines have been made and brought to the point of production since work on the Giroux was first started, and it is still in the formative stage.

Utah Copper's last quarter broke records for monthly output of copper and also established a new low cost record. The cost sheet for the entire quarter shows an average cost of 7.56c. per pound, against 8.02c. for the preceding quarter. September costs were 7.18c., the lowest yet made for any one month. For the quarter, the company earned $361,700 over and above dividend requirements. For the first nine months of the current year, surplus above dividends is $554,000.

It is said that the Phelps-Dodge company will probably cut its annual dividend from $12 to $10, in view of the conditions prevailing in the metal market. On the other hand the Greene-Cananea is expected to come back into the dividend list within a short time.

The echoes of the Calumet & Hecla merger litigation have not all died out. The Ahmeek interests, headed by the Chadbournes, not content wtih having blocked the merger, are praying the court for a decree of perpetual injunction against the consolidation, which would rather appear to be rubbing it in.

Nipissing is to have a Butters mill for the reduction of its low-grade ores. Charles Butters is now at Cobalt making preliminary tests to determine just what kind of a plant shall be erected. The two leaders in the Cobalt list have somewhat disappointed their followers during the current year. Nipissing has a large territory, by far larger than any in the camp, and heretofore has been able to prospect always with good results; of late, however, diligent trenching has not opened the usual number of good showings. The market has reflected conditions faithfully and Nipissing has sold off on what appeared to be real liquidation. La Rose has been divided against itself. Some months ago the dividend rate was lowered, and a considerable surplus has been accumulated. In the meantime known ore reserves have apparently not been increased and the management has felt that surplus funds were needed for some broader exploration work. Some of the stockholders have clamored for a return to the previous dividend rate, and the whole matter has been postponed till after the first of the year. There has been very little of interest as regards Porcupine recently. The most important deal recently was the sale of a controlling interest in the North Dome to the Temiskaming Mining Company.

General Mining News

ALASKA

Juneau

The report of the Alaska United G. M. Co. for the 15 days ended September 30 shows a net profit of $15,620. The mills of the Ready Bullion and 700 Ft. claims treated 18,730 tons of ore, from which 400 tons of concentrate was saved. The realizable value of the production from the two claims was $44,159.

The Alaska Mexican G. M. Co. in the 15 days ended September 30 crushed 8976 tons of ore, from which 238 tons of concentrate was saved. The net profit for the period was $7589.

RAY, ARIZONA, SHOWING CENTRAL PORTION OF ORE-ZONE.

Ketchikan District

(Special Correspondence.) The Wetzel property at sea-level has been bonded to a company represented by M. M. Churchill. A tram is being built to tidewater for shipping ore taken out during the process of development. The ore content principally is gold. About 700 tons of high-grade ore is nearly ready for shipment at the Rush & Brown mine. The development is being carried on by the owners.

The Princeton M. & M. Co., at Dolomi, is blocking out and prospecting orebodies preparatory to erecting a 20-stamp mill. Patrick Heaney, of Butte, Mont., has charge of the mine. Several discoveries have been made on the Salmon river at the head of Portland canal. The latest of these was by Ickis & Polson, about 7 miles up the river, and is a well defined quartz fissure vein nearly 4 ft. wide, heavily mineralized with galena and iron pyrite. A similar vein was located last year by Lindeburg Bros., about 400 ft. to the north and parallel to it. It has been traced over 2000 ft. by stripping and open-cut work. Both of these veins cut through granite. Johnson & Rowlee, Peterson and Pearson, McGrew company, and several others have made promising finds on the American side of the line during the summer.

Some important surface showings of galena ore have been exposed on the headwaters of the Salmon near the boundary between British Columbia and Alaska. Development is being carried on by the Indian Mines Co., Cascade Falls M. Co., Salmon Bear River company, and the Bruggy group of claims. These claims are on the British side of the boundary line.

The winter season will soon put a stop to prospecting in this part of the country until next spring. Surveys are now being made for a proposed railroad up the Salmon river, this being the only feasible route that will give direct connection to tidewater.

Ketchikan, November 1.

ARIZONA

Gila County

Press reports state that rich chalcocite ore was discovered recently on the Miami Development Co.'s property, which lies between the Live Oak and the Barney.

Pima County

Development work at the Camp Madera mine is to be started in the near future. The new machinery for the mine has been erected. In the equipment are a 35-hp. engine, an air-compressor, and a 1¾-in. drill. H. E. Brandt, formerly of San Francisco, is president of the company.

Pinal County

(Special Correspondence.)—The Ray Central Copper M. Co. is making preparations for the construction of a mill and surface plant which will include shops, compressor-house, hoist-house, steel head-frame, crusher-house, and power-house. The mill will have a nominal capacity of 1500 tons and will be designed by H. Kenyon Burch, designer also of the Moctezuma Copper Co.'s mill at Nacozari and of the mill of the Miami Copper Co. Mr. Burch is now at the mine working on the preliminary plans. E. Horton Jones, formerly constrution engineer for the Ray Consolidated, will occupy a similar position with the Ray Central. A new working shaft will be sunk near the east end of the Isabella claim. It will have four compartments, will measure 7 by 28 ft. in the clear, and will be 500 ft. deep. Ore will be hoisted in six-ton skips. An adit will be started at the elevation of the present first level and will be driven to the shaft. This will be used only for timber and supplies. The shaft will be driven almost entirely by raising, and driving is in progress on several levels toward its proposed location. Assessment for the current year on all unpatented claims has been completed. F. H. Probert, consulting engineer, is now at the mine.

The Ray Con. Copper Co. is mining and milling 4000 tons of ore per day with four of the eight units of the mill in operation. The ore is coming from the stopes of No. 1 mine and from the development work in No. 2 mine. The surface plant at No. 2 shaft is practically completed and will soon be ready for operation. Messrs. Jackling, Penrose, Aldrich, and McNeill are expected at the mine in a few days.

Globe, November 2.

CALIFORNIA

Butte County

The Superior Channel Mining Co., of Arizona, has been formed by E. Conger and F. C. San Souci. A branch of its principal place of business is to be at Chico.

Nevada County

(Special Correspondence.)—The Pennsylvania M. Co. is erecting the 10-stamp mill recently purchased from the Morning Star company. It will give a milling capacity of 30 stamps. The company is concentrating its activities on the Pennsylvania portion of the group, and arranging for heavy production. The Lucky vein has been found near the 600-ft. level of the Union Hill by the diamond-drill. The 500-ft. cross-cut will be driven about 50 ft. farther to open the vein, and connections made with the 300-ft. level. The new mill is rapidly nearing completion, while a large reserve of milling quartz is blocked out in the main Union Hill workings. Clifford Graham is superintendent of the property. The North Star Mines Co. has installed new cables in the Providence shaft of the Champion group, Nevada City district, and the electric pumps soon will be in position. The Andy Fitz company has decided to continue operations at the Fruitvale mine throughout the winter. The adit will be continued until the vein is tapped, and a raise put through to surface, a distance of about 400 ft. The property is situated on the Middle Yuba river, below Moore's Flat. Andy Fitzgerald is superintendent. The Oakman company has purchased the 10-stamp mill formerly operated at the Kentucky Ridge mine, and expects to have it in commission early in January. The Oakman is situated four miles above Washington and is owned by Massachusetts people. The 1200-ft. adit recently intersected a vein of free-milling ore at a depth of about 600 ft. The vein is 6 ft. wide and assays about $8 per ton. Frank Dillon is manager of the mine.

Grass Valley, November 6.

The electric conduit to be used at the Champion mine in connection with the electric pumps is now being placed, states a report from Nevada City.

Sacramento County

Amended articles have been filed by the Natomas Consolidated providing for thirteen instead of eleven directors.

Shasta County

George Bayha, a mine promoter representing German capitalists, has bought the Golinsky group of copper mines, west of Kennett, for $100,000 from Bernhard Golinsky. Mr. Golinsky located the claims, 14 in number, fourteen years ago. Four years ago the Guggenheim interests took a bond on the properties, the price to be $100,000, to be paid for with 50% of the returns from the ore extracted. The Guggenheim company built a railroad three-fourths of a mile long to connect with the Holt & Gregg line, and in less than six months shipped 3500 tons of ore to the smelter at Garfield, Utah, while Mr. Golinsky expected the ore to be smelted at Kennett, although the place was not specified in the bond. The ore milled 9% copper. The 1907 panic is said to have been the direct cause of the Guggenheims not taking the property.

Sierra County

(Special Correspondence.)—The upper and lower levels of the Tightner mine have been connected by a raise, and a bulkhead will be placed in the upper adit to prevent damage to No. 4 level by cave-ins. The lower adit will be continued to the Red Star vein, and ore will be extracted from the Tightner vein in the meantime. In the upper workings sufficient ore has been proved to keep the 10-stamp mill in commission during the winter, it is said. C. C. Derby is manager of the property. The new company which recently acquired the Sixteen-to-One is planning vigorous development. It is believed the vein will be recovered by further driving. Electric power has been obtained by the North Fork Placer company to operate the drills and pumps. A cross-cut is being driven toward the Uncle Sam vein. George F. Stone is manager.

Dan McGonigal and associates are planning extensive work at the Kate Hardy. The main vein is reported to range from 20 to 40 ft. wide, with occasional bunches of bonanza. The property has been opened by adits driven from the Oregon creek side of the workings. The Poker Flat Deep Channel M. Co. has been reorganized. Sinking of the 350-ft. shaft has been resumed. M. Duvall is manager for the company. The Round Lake M. Co. has made final payment on the Dixie Queen group, near Downieville. The mine is a quartz property and has a good body of milling ore opened. Martin Miller is superintendent for the company.

Alleghany, November 4.

Work has been started on enlarging the Alaska mill, near Pike. Twenty stamps will be added, which will make a total of 40 at the mill. R. L. Hathway, of Nevada City, is in charge of the construction work.

Trinity County

The Trinity Con. Hydraulic M. Co. of America has been incorporated to develop the extensive placer deposits in the Weaverville basin, recently acquired for a group of New York capitalists by W. A. Boland. The rumor that the Guggenheims are interested in the undertaking has been officially denied. Mr. Boland, after inspecting the properties last March, formed the plan of organizing the various properties under one management. Some of them had not been in full operation owing to the lack of sufficient water. Mr. Boland announces that there will be more than enough water available through plans already completed. D. W. Shanks, who is interested in the Rio Plata company of Mexico, and the Trinity Gold M. & R. Co. of California is general manager for the new company, of which Henry W. Miller is president, Mr. Boland vice-president, and J. H. Lee secretary and treasurer. The company already has acquired the Union Hill, the Hupp, and other properties.

Tuolumne County

The extensive caving in of the surface on the Heslep claim at the App property, at Quartz mountain, on October 28, filled the old workings above the depth of 300 ft. and dislodged timbers down to the 600-ft. level, quaking the ground within a radius of four miles. The chasm opened by the falling in of the ground is about 150 ft. deep, 200 ft. long, and 150 ft. wide. The large pipe through which runs the water to operate the mill was broken, causing an interruption in operations lasting several days. None of the workings of the App proper were damaged. Contrary to the original belief, the collapsing of the ground is regarded as rendering easier the extraction of some 100,000 tons of ore.

The Big Four mine, owned by W. D. Deming and George Wilds, and situated near the old Dead Horse, has been bonded to R. E. Edgar, of Los Angeles. Development work is now in progress. The winze started by the owners 500 ft. from the mouth of the adit, in a 2-ft. orebody assaying from $10 to $50 per ton, will be sunk to 100 ft., after which, if prospects are satisfactory, a raise will be run to the surface and hoisting machinery installed. Simultaneously driving will progress from the bottom of the winze.

A small vein of rich ore has been uncovered in the shaft being sunk at the El Dorado mine, at Cherokee. The main vein has not yet been reached. The property is owned by the Sivori brothers of Tuolumne.

Another body of rich ore is said to have been uncovered in the New Albany mine. An assessment of 10c. per share, payable before December 9, has been levied upon the capital stock of the Mohican M. & M. Co. The work of unwatering the Draper mine has progressed to the 400-ft. level.

Improvements are being made at the Harvard for the comfort and convenience of the employees. A heating and drying apparatus and a hot and cold water system are being installed in the new change room, in which will also be put a shower bath equipment and individual lockers for the workmen. The buildings on the property are being painted.

Tuolumne, November 4.

COLORADO

Clear Creek County

(Special Correspondence.)—Von Tilborg and White, leasing on the Gem mine, have uncovered a body of ore 2 ft. wide that assays $100 per ton, and 5 ft. of mill ore. The discovery was made at a depth of 2200 ft. and 1100 ft. east of the lateral run from the Newhouse adit. The Lucania T. Co. will start development upon a number of veins as soon as the contractors complete their work in the adit. John McColl is manager. The Smith property on Santa Fe mountain is showing a streak of ore 3 in. wide that assays 948 oz. silver and 0.40 oz. gold. R. E. Farmer is owner. L. Sternberger, manager for the Pennsylvania M. Co., states that a lateral will be driven eastward 1000 ft. on the J. L. Emerson vein that was recently intersected by the Lucania adit. A raise is to be put through from the Lamartine adit-level to connect with the workings above. It will be 360 ft. high. F. W. Himrod, of New York, is owner.

Idaho Springs, November 5.

(Special Correspondence.)—A vein of ore 2 ft. wide has been found in the lower level of the Millington mine on Columbia mountain that assays 700 oz. silver per ton. Connerry and Eade are operating under lease. Work has been resumed on the Paragon adit situated on Bard creek. Charles Coggswell is manager. A new company has been formed to take over the Sporting Times mine on Alpine mountain. Philadelphia capitalists are interested. C. D. Colburn will be manager of the property. The Tom Payne mine on Democrat mountain has been purchased from E. K. Cass by H. Lendecke. Shipments of ore are being made by the Paymaster mine in East Argentine. The product is a silver-lead and brings $90 per ton. A body of ore 18 in. wide has been found on the third level of the Mineral Chief mine that assays 70% lead and 45 oz. silver per ton. The vein is exposed for a distance of 300 ft. A. L. Stephens is manager. The Mammoth mine on Brown mountain has been taken under a $15,000 bond and lease by W. A. Patton, representing Denver men. Development will start soon. G. Oxley, of Idaho Springs, has taken a lease on the 100-ft. level at the Capital mine. Stoping has been put under way on a 6-in. streak of 2.30-oz. gold ore. Eade & Co., leasing in the west drift on the Aetna vein at the Capital mine, has found a 10-in. vein that assays 2.70 oz. gold, 14 oz. silver, 5% copper, and 22% lead per ton. Shipments have been started.

Georgetown, November 4.

At the Baker mine in the West Argentine district ore assaying from $45 to $60 per ton recently was discovered. Development is to be resumed on a large scale at the Josephine mine on Kelso mountain, as the legal troubles over the property have been settled. Previous to the suspension of work, six months ago, the mine produced about $12,000 per month.

Dolores County

The Rico Mining Co. has been incorporated by D. B. Ellis, S. T. Hawthorne, and C. I. Hawthorne. The company, which will have its main office at Rico, is capitalized at $3,500,000.

Ouray County

Mrs. Julia E. Dunn, of Grand Junction, has purchased the Mirren group of claims, situated near the Camp Bird for $40,000. The Mirren group is believed to be on the extension of the Camp Bird veins.

San Miguel County

The report of the Tomboy Gold Mines Co., Ltd., under the management of the Exploration Company, Ltd., of London, for September, states that the mill crushed 9300 tons of ore, from which $54,000 worth of bullion was extracted. The concentrate shipped amounted to $30,000, making a total production of $84,000. The expenses were $41,500, leaving a net profit of $42,500.

The General Vanadium Co. recently shipped a car of high grade vanadium ore to Liverpool.

Teller County (Cripple Creek)

The Miami Mining Co. has been organized to carry on mining operations in the Cripple Creek district. The main office is at Colorado Springs. The organizers are H. E. Schneider, J. O. Henry, and G. M. Irwin.

The October production of the Vindicator main shaft was 52 cars of ore, assaying about $35 per ton. The ore was principally from the 14th and 15th levels.

TOMBOY MINE.

The Vindicator Consolidated has just paid a dividend of 3%, aggregating $45,000. The total paid in dividends by this company to date is $2,407,500.

Since the resumption of work in the heading of the Roosevelt drainage adit, it has been driven about 100 ft., and the length of the adit is now 15,800 ft. The flow amounts to 6500 gal. per minute. The El Paso company is repairing the track in the Fuller cross-cut preparatory to starting work on the main C. K. & N. vein.

A 3-ft. vein of ore assaying $80 per ton has been discovered on the Kitty Wells claim, on the south slope of Carbonate hill, by W. A. Thompson, lessee of the property, state recent reports from Cripple Creek.

For October the production of the mines in the Cripple Creek district amounted to 77,728 tons, and its estimated gross value was $1,318,199. In the following table the tonnage handled by the smelters and the various mills is given, together with estimates of the value:

Plant.	Tons.	Av. val.	Gross val.
Smelters	3,825	$55.00	229,500
Golden Cycle	23,000	20.60	520,000
U. S. R. & R.	13,050	21.50	280,575
Portland, Colorado City.	9,700	20.00	194,000
Portland, Cripple Creek.	11,520	3.25	37,340
Stratton's Independence.	10,522	3.16	33,240
Wild Horse	1,200	2.30	2,660
Isabella	900	1.20	1,080
Jo Dandy	1,000	4.20	4,200

The October output of the Forest Queen mine on Ironclad hill was 22 cars. The ore, which assayed about $35 per ton, was largely from the flat vein discovered on the

500-ft. level. Richardson & Richardson, last month, operating a block of ground on the El Paso property, shipped 14 cars of ore. The usual production is about 15 cars.

IDAHO

BONNER COUNTY

Work has been resumed on the Diamond Jim, a silver-lead property on the shore of Lake Pend Oreille on Blacktail mountain.

IDAHO COUNTY

The Hydraulic Placer M. Co. of Spokane is ready to begin washing on its gold bar in the Salmon river, 15 miles from its junction with the Snake river. E. M. Bates, who has just returned from an inspection trip, reports that everything is in shape for the operation of the hydraulic system. The flume is ready and the men are completing the sluice-boxes. The company has an unlimited supply of water and will operate two giants under pressure of 100 lb., and expects to wash 1000 cu. yd. of gravel per day. It is estimated the gravel will average $2 per cubic yard.

LEMHI COUNTY

Since the completion of the Gilmore & Pittsburg railway two mines have shipped more than $1,000,000 worth of lead-silver ore, according to recent reports. There are no mills in the camp, and mining appliances are of the simplest character. The Pittsburg-Idaho and Latest Out are the principal shippers. They are sending 3000 to 4000 tons of ore per month to Salt Lake smelters.

The Kirtley Creek Gold Dredging Co. is reported to be successfully operating its 9-cu. ft. dredge, costing $200,000, five miles from Salmon. It is estimated that it will require six years to clean up the ground available. The plant is run by electricity.

MONTANA

LINCOLN COUNTY

(Special Correspondence.)—Wm. Criderman, of Libby, has sold to W. H. Graham and his associates 680 acres of placer ground on Libby creek for $28,000, and it is the intention to install a large hydraulic plant on the property. Mr. Graham is from San Francisco and until recently was connected with the Snowshoe mine. Included in the deal is an extensive deposit of fine marble, in which are 26 distinct colors of the stone. Of the purchase price, a small cash payment has been made, and the balance is to be paid within 12 months. Mr. Graham said he intended to begin operations at once with a prospecting drill.

Arrangements will be made at once to have the ground surveyed for a pipe-line, and in the spring a hydraulic plant will be placed. A pipe-line two miles long will be constructed and two 4-in. nozzles will be used. The pipe and all other machinery will be taken in on the snow during the coming winter. The same drill will be used that was brought in here by J. Y. Ownbey and his associates last summer. This drill was used to sink some holes on this ground, and some remarkable gravel was found. The property lies about 15 miles south of Libby.

Libby, November 3.

SILVERBOW COUNTY

(Special Correspondence.)—The Anaconda company is keeping every mine under its control in a complete state of repair. Whenever a property is closed down, through any cause, the opportunity is at once seized to make a careful examination and make repairs and improvements which might not otherwise be undertaken for six months or a year. This was the case with the High Ore when it was shut down last August to change the engines for operation under the compressed-air system. For quite a long time it was planned to replace the cages for hoisting ore with skips, and while at first it was not intended to do this until next spring, the time was considered a good one, so the work was commenced, and now skips are being installed. The work will be completed about the time that the engines will be ready to go into commission, which will be about the first of next month. The substituting of skips for cages is to prevent trouble in the stretching of the rope attached to the cages in the long haul of 2800 ft., the deepest level of the mine. On a loaded cage on the long haul there is a stretch in the rope of several inches, and while it is not contended that the use of the skips will have anything to do with the lessening of the stretching of the cable, it is believed that there will be less cause for trouble.

The new compressor for the Raven M. Co. has arrived and in the course of a week or ten days it will be erected. Work is to be started as soon as the compressor is in commission to drain the 1300-ft. level, after which it is intended to start uncovering some rich orebodies which are believed to exist on that level. On the upper levels lessees still continue to get a good grade of shipping ore, and according to all reports they are making much more than expenses.

Butte, November 4.

NEVADA

CHURCHILL COUNTY

Press reports state that the vein recently found on the Kinney & Leonard property at Sand Springs is now producing ore assaying 60 oz. of silver per ton, and that the vein is widening.

ESMERALDA COUNTY

The October production of the Goldfield Con. M. Co. was about 30,626 tons of ore, valued at $805,000, according to the preliminary estimate of J. F. Thorn, general superintendent for the company. The operating expenses were about $205,000, leaving a net profit of about $600,000 for the month. The average assay-value of the ore was $26.28 per ton. This is the largest tonnage ever produced by these mines in one month. The company shipped $238,000 worth of bullion on October 25, and $81,000 worth of bullion October 30, to the Denver Mint. The bullion was refined at the company's refinery and was about 950 fine.

Two lessees working on the estate of the C. O. D. Consolidated are making shipments. Six lessees, in all, are operating. The Lowden-Hardwick lease on the Victor has penetrated 3 ft. of ore which assays about $200 per ton, and the Gold Bar lease, in charge of Harry B. Ruhl, is developing a 2-ft. vein which assays about $300 per ton, state recent advices from Goldfield.

The electric hoist for sinking the winze from the 300-ft. level of the Goldfield Belmont is now in operation. A cross-cut will be driven to tap the vein at a depth of about 60 ft. The winze is being sunk vertically.

The Comet mine, operated on lease by a man named Wolfe, has reverted to the owner, T. A. Maher. The latter states that a vein of silver and copper sulphide ore was discovered after the claim reverted to him, and that the outlook is good for extensive development.

NYE COUNTY

The Tonopah Belmont Dev. Co. is to resume sinking its main shaft immediately, and an auxiliary electric hoist and sinking pump have been erected on the 12th level. The erection of the steel frame for the tube-mill is to be started at once. The production last week amounted to 2500 tons of ore, according to recent news despatches.

It is reported that the North Star will start shipping ore in the near future. The company is to build ore-bins and a loading station on the switch of the Montana-Tonopah M. Company.

The monthly report of the Tonopah Extension M. Co. shows that 4420 tons of ore was treated, the recovery being 90.6%, and the average value of the ore $12 per ton. The company shipped 4861 lb. of bullion, valued at $50,000. The estimated net profit, including the clean-up for the latter half of the month, was $23,000.

The Tonopah M. Co. last week shipped 3700 tons of ore. Prospecting is in progress in the vicinity of both the hanging wall and the foot-wall of the main veins, and several new orebodies have been found, according to recent reports. The improvements were in the Mizpah, Silver Top, and Desert Queen mines. The West End Con. M. Co. reports good milling-grade ore found on the 500-ft. level. The latter company last week shipped 500 tons of ore.

The Montana Tonopah company shipped 1043 tons of ore. The monthly clean-up is being made.

Storey County

The October production of the Comstock mines was the largest for several months, according to the weekly reports of the various mine superintendents. The production of the Ophir, Mexican, and Crown Point mines reached a total of $164,981.

The Comstock mines last week produced $38,925 worth of ore, the Ophir mine leading with a production of 348 tons of ore, valued at $20,487. The Mexican mine was second, with a production of ore valued at $15,010. The 2100 and 2200-ft. level stopes of the Ophir continued their noteworthy production, the ore averaging in value $58 per ton. On the 2400-ft. level the development is in quartz, with low grade ore.

White Pine County

Press reports state that the preliminary work for the standard-gauge railroad from the Morris shaft of the Giroux to the concentrator, has been finished, and that construction work will be started immediately.

Development work on the Ely Calumet property is to be resumed in the near future, under the direction of A. D. Myers of Los Angeles, says a recent despatch from Ely.

Work at the Veteran will be resumed probably next week, when the electrical work will have been completed. John McDonald, the new manager of the mine, is now at the property.

NEW MEXICO

Socorro County

(Special Correspondence.)—Two mortars for a new battery have been delivered at the Ernestine M. Co., and a bed plate and a fly-wheel for one of the oil engines will arrive at the works about the middle of next week. The rest of the new machinery will be rushed from Silver City as fast as possible. Last week 742 tons of ore was treated. The bullion production for the second 10-day clean-up in October was 9240 oz. of gold and silver; 4½ tons of concentrate was shipped during the period. The new shaft of the Oaks Co. has been sunk 12 ft. at the north end of the Pacific mine, and timbering the south shaft has been started. The president of the Treasure M. & R. Co. has been on the ground for two weeks, during which period the final survey for a gravity wire-rope tramway was made. White Water creek is furnishing ample power to operate both mine and mill, and steady production is being maintained.

Mogollon, November 3.

OREGON

Baker County

The West Coast M. Co. has been organized by W. J. Woods, F. H. Perry, and S. O. Correl to do a general mining business. The main office will be at Baker.

UTAH

Salt Lake County

(Special Correspondence.)—The Utah Copper Co.'s report, for the quarter ended September 30, shows an increase in production, as was anticipated, and the lowest cost per pound in the history of the company. The output for the three months was 25,851,456 lb., as compared with 25,469,812 lb. for the previous quarter and 21,296,709 lb. for the first three months of the year. The net average cost for the quarter, after deducting allowances for smelter and without crediting miscellaneous income was 7.56c. per pound, while in September it was forced down to 7.18c. for the monthly average. The cost during the previous quarter averaged 8.02c. per pound. The company made a net profit for the quarter of $1,538,712, including $375,187 Nevada Con. dividends. It paid $1,177,012 dividends and added $361,700 to surplus. The ore handled showed a falling off in grade, being 1.4829% copper, as compared with 1.6332% copper for the previous quarter. The tonnage was increased from 1,060,414 to 1,273,373.

Salt Lake City, November 6.

Tooele County

(Special Correspondence.) The Con. Mercur G. M. Co. is showing a remarkable amount of vitality, when one takes into consideration the pessimistic tone of the last annual report, in which the permanent closing down of the mine was foreshadowed as more than a possibility. September showed a profit of about $2000, and October about the same. Prospecting work is being carried on vigorously, and the hope is expressed that new and profitable orebodies may yet be opened up in the old property. The Consolidated Mercur company since its organization in 1900 has produced $9,746,041 in gold, while the constituent properties produced nearly as much before the consolidation. There are 340 men employed at the Con. Mercur, which constituted the sole support of the town of Mercur, and John Dern, president of the company, has promised to keep the property running as long as it can be done without a steady loss.

Mercur, November 4.

CANADA

British Columbia

Development work at great depth will be pushed on the Slocan Star group in the Slocan district, near Sandon, according to Byron N. White of Spokane, who is interested in the property. The group has been consolidated with the Rabbit Paw claims under the title of the Slocan Star Mines, Ltd., with R. S. Lonnie of Vancouver as president. The company is capitalized at $2,500,000. The concentrator will be in operation in a short time. The property has been developed on the Slocan Star, Silversmith, and Heber Fraction claims to 600 ft. It has produced ore valued at $2,500,000 and has paid $542,000 in dividends, in addition to defraying all costs of original purchase, prospecting, development, and equipment, including the mill near Sandon, according to recent reports. The cost of the projected development work, including the remodeling of the mill and the erection of new buildings, will amount to about $40,000. The mine has been idle for ten years, due to litigation over the question of extralateral rights between the owners of the Slocan Star and the Rabbit Paw groups. The controversy has been adjusted.

W. E. Swickey, of Spokane, manager of the Rambler-Cariboo mine, is preparing to start work on the Payne mine, situated in the Slocan district. The adits are being cleared preparatory to opening the property. The plans for development include a lower adit.

Ontario

The O'Brien company on October 31 shipped to London 21 bars of bullion valued at $10,713. The Drummond mine also shipped to London two bars valued at $752. The Nipissing property shipped 65 bars of bullion valued at $40,210.

MEXICO

Hidalgo

The La Blanca y Anexas company has taken options on the Cinco Señores and La Purisima properties, which it is believed, are traversed by the veins of the La Blanca and Santa Gertrudis mines. The price to be paid is ₱600,000, to be paid in two years. The option has been running for some time, and a thorough investigation will be made, state reports from Pachuca. The ground is between the La Blanca and the Santa Gertrudis.

The Santa Ana mine is now making regular shipments to the San Francisco hacienda over the railroad recently completed.

The Santa Ana y Anexas company has completed the extensive precautionary measure planned for the handling of its production. The work was in charge of Thomas Morcum.

Oaxaca

The San Juan M. Co. has prepared plans for a 200-ton mill to treat the ore from its San Juan mine in the Taviche district. The company recently installed a new hoist. Press reports state that it is shipping $100,000 worth of ore per month. The shaft, now down about 700 ft., will be sunk to a depth of 1500 or 2000 feet.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

ALBERT BURCH is at Goldfield.

HENRY JANIN is in San Francisco.

FRANK KEEVER is in San Francisco.

DAVID GOODALE is in San Francisco.

DUNCAN MACVICHIE is in New York.

O. BERGSTROM has been in San Francisco.

COURTENAY DE KALB has gone to New York.

G. W. HEINTZ has returned to Salt Lake City.

S. L. KNOX, of El Paso, Texas, is in San Francisco.

J. L. KING, of Denver, was in San Francisco recently.

GELASIO CAETANI is expected to return from Colorado today.

CHARLES JANIN has gone to the dredging fields of California.

H. W. REED, of Salt Lake City, is at Long Beach, California.

E. H. HOAG, of San Francisco, is at Mazatlan, Sinaloa, Mexico.

MALCOLM MACLAREN is now at Jackson, Amador county, California.

W. F. ENGLEBRIGHT, of Nevada City, California, is in San Francisco.

EDWIN E. CHASE will be at Parral, Chihuahua, Mexico, during this month.

JOHN A. STREET, of Salt Lake City, is at the Palace hotel, San Francisco.

FRANK LANGFORD has left Rancagua, Chile, and is at Eureka, California.

ARTHUR W. BURGREN is engaged in mining operations at Minillas, Zacatecas, Mexico.

C. W. PURINGTON is in London and will return to St. Petersburg early in December.

WALTER W. DAVIS is now general manager for the Smuggler mines at Aspen, Colorado.

ARTHUR L. PEARSE has arrived from London, and is staying at the Palace hotel, San Francisco.

Inquiry is made for the address of JAMES LESTER, who is associated with the Tramp claim in Nevada.

EDWIN J. COLLINS, of Duluth, is examining some gold properties in El Dorado county, California.

L. L. JAMES will return to Fairbanks, Alaska, from San Francisco, where he has spent nearly two months.

WALDEMAR LINDGREN has accepted the office of Chief Geologist of the United States Geological Survey.

CHARLES N. GOULD has resigned as director of the Oklahoma Geological Survey, and will take up private practice.

W. H. EMMONS, of the State University of Minnesota, has been elected director of the Minnesota State Geological Survey.

ALFRED HASELBRINK, who is in the Prussian Government Mining Service, was in San Francisco, and has gone to Salt Lake City.

C. COLCOCK JONES has returned to Los Angeles after a month's absence in the Lake Superior and Pittsburg regions on professional business.

RALPH B. WILLIAMS has moved from Newburyport, Massachusetts, to Minas Pecolotes y Anexas, Santa Barbara, Chihuahua, Mexico.

CHESTER B. ALLEN, resident manager for the United Gold M. & M. Co., has been inspecting hydraulic mining properties in Trinity county, California.

REUBEN W. LEONARD has been appointed, by the Canadian Government, chairman of the National Transcontinental Railway Commission, which has charge of the construction of the eastern section of the Grand Trunk Pacific.

Company Reports

CONSOLIDATED M. & S. CO. OF CANADA, LTD.

The net profit of this company for the year ended June 30 was $202,278. Added to the balance of the profit and loss account of the previous year, this makes a total for that account of $873,289.

The tonnage of ore handled at the smelter was 388,785 tons, as against 487,125 tons in 1910, the decrease being mainly due to the abandoning of the Snowshoe lease. The bank overdraft, however, has been reduced by the sum of $181,980, which is considered satisfactory in view of the unfavorable conditions existing during the year. The capital stock has been increased by the issue of 2500 shares of the par value of $100 each. These were subscribed for at par and realized $250,000 cash. This amount was expended partly in purchasing stock and bonds of the Fort Steele Mining & Smelting Co., owners of the Sullivan mine, and partly in development of other properties.

The property and plant accounts, after writing off $193,342.27 from the profits of the year, show an increase of $171,533.63 over last year. Since June 30 the directors have purchased from the liquidator all the property of the Le Roi Mining Co. at Rossland.

The gross value of metals produced at the company's smelting works for the year was $4,437,901, as compared with $5,911,767 for the previous year, a decrease being shown in all of the metals. There was an increase in the production of the Centre Star and Sullivan groups, the Molly Gibson and Number Seven have entered the list of shippers, and the remainder of properties show a decrease. The large decrease in total production is due to the working out of the St. Eugene, dropping the Snowshoe lease, and to the fire in the Slocan a year ago, which closed down the Kaslo & Slocan railway and caused a large decrease in shipments from that district.

In the Rossland mines, ore developed and shipments have about balanced. Although the tonnage developed was numerically less than for the previous year—194,000 tons as against 245,000 for the year 1910—the average value of the ore developed this year on the lower levels was higher.

BROKEN HILL PROPRIETARY COMPANY, LTD.

The report for this company for the six months ended May 31 shows a profit for that period of £126,800, as against a profit for the preceding six months of £102,928. Among recent improvements by the company is the introduction of mechanical feeders at the Port Pirie smelter, which will eliminate the uncertainty of labor supply. As the machinery allows a saving of about £30 per day over manual labor, it is estimated that it will pay for itself in two years. Construction for the Dwight-Lloyd process, which had been delayed by the non-arrival of the machinery, is being rushed and should be completed by the end of November.

Compressed-air pumps have given place to electric pumps. This form of pump is now being erected at the 1200-ft. level. Important improvements have been made in the concentrating plant. During the period covered by the report 52,441 tons of ore was treated in the old mill, and in the new mill 159,609 tons of tailing was treated. As the sulphuric acid plant has not been working at full capacity the cost of operation has been higher than otherwise would have been the case. The acid produced amounted to 2626 tons, as against 3432 tons during the preceding six months. Three roasters have been in operation on zinc concentrate and treated 1897 tons. The sulphurous gas obtained from the concentrate was equivalent to 376 tons of crude sulphur. The zinc-separation plant, in spite of Christmas and Easter cessations, treated practically the same tonnage as during the previous half-year. A permanent plant for slime treatment is planned, as an experimental 10-ton plant has been quite successful. Owing to the success of the flotation process it is probable that the sintering works will be abandoned.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS

INJURY TO MINER—ASSUMPTION OF RISK

In the operation of a mine it was the duty of the mine owner to furnish props to support the roof and it was the duty of the miner to set such props as the work progressed and the end of the room of the mine was extended. In the operation of the mine the miner was killed by the falling of the roof. The undisputed evidence showed that the deceased was an experienced miner and knew the necessity of propping the roof as he advanced farther in his work and of the danger of its falling if not properly supported, and that when he went to work the morning of his death he, with his assistant, examined the roof and it seemed all right. It appeared also that he worked from two to four days without putting up props and then called on the mine foreman for props and was told to go ahead with the work and the props would be sent and that the deceased did thereafter work extending his room when the unsupported roof fell and killed him. In continuing his mine and extending his room without propping the deceased well knew and appreciated the danger and assumed the risk although the mine owner neglected to furnish the necessary props. It is not a case of a master furnishing a defective appliance or a place which he promises should be repaired and made safe; but it is a case where assurances of safety was given to the servant who was making his own place to work which he knew as well as any one could know would be and was dangerous without using the appliances the master promised to furnish, and which he knew had not been furnished, and he well knew in continuing to work therein he was in danger and was increasing the danger with every stroke of the pick, as he was an experienced miner and well knew the necessity of propping the roof as he advanced. Under such circumstances the deceased had no right to rely either on the statement of the foreman that the top was all right or that the props would be furnished at some future time. Under such circumstances the Federal court held that as a matter of law the deceased, in continuing to work in the mine in the absence of sufficient propping to support the roof in his room assumed the risk of injury from the falling roof and the mine owner was not liable.

Republic Iron & Trust Co. *v.* Thomasino, 176 Federal, 49. Feb. 1910.

CONSTRUCTION OF LEASE OF MINE—IMPROVEMENTS

A lease of a coal mine and appliances provided that the lessee should be paid the value of all permanent improvements made by him, not exceeding $5000, to be ascertained by arbitration. The lessor had the option to pay or not to pay for such improvements, and if he elected not to pay the amount fixed by the arbitrators the lessee had the right to remove such improvements. In an action between the lessor and the lessee it was held by the court that when the lessor elected not to take and pay for the improvements the lessee had the right to remove them; but where the lessor did not elect not to take the improvements, and they were left on the leased premises, the lessor was chargeable with the reasonable value of such improvements not exceeding $5000. It was also held that the amount of damages sustained by the lessor by reason of the failure of the lessee to return the mine in better condition and repair than when he received it, as provided by the lease, was a question of fact to be determined by the jury, and the court on appeal would not disturb the finding of the jury as to the amount of such damages; and in order that the jury might determine the amount of the damages, it was proper for the court to order an inspection of the premises and to permit the lessee to enter upon the property and pump the water out of the mine, so that witnesses could make a proper inspection and testify accordingly.

Merriam and Harold C. Bryant. University of California Publications, Bulletin of the Department of Geology, Vol. 6. No. 13 and 14. Pp. 16. Berkeley, California, October 1911.

Astronomical Field Tables for the Use of Engineers and Surveyors. Instructions Covering Astronomical Tables. The Topley Co., Ottawa, 1911. 16 pp. each. These two booklets, issued by the Topley Co., will prove useful. The tables are issued in four parts, covering the period from November 1910 to August 1913. However, September 1911 is in part 1, with August 1912, while March 1911 is in part 4, with June 1912, an arrangement which scarcely seems likely to conduce to convenience. The instructions for the use of the tables are in a separate booklet, but this has the advantage that an engineer familiar with the use of tables need not cumber his notebook with unnecessary material.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the Mining and Scientific Press.

Uruguay. By W. H. Koebel. Charles Scribners Sons, New York, 1911. 350 pp., ill. Price $3. For sale by the *Mining and Scientific Press.*

This volume is the sixth of a series on South America, published by Charles Scribners Sons, the preceding volumes having dealt with Chile, Peru, Mexico, Argentina, and Brazil, respectively. Mr. Koebel, who is well known for his writings on South America, after a general description of Uruguay, devotes eight chapters to its history. This is followed by chapters on Uruguayan manners and customs, the aboriginal tribes, and ten chapters descriptive of travels throughout the republic. Chapters on Uruguay as a pastoral country; departments, climate, and natural history; industries and natural wealth; communications and commerce follow, and a discussion of politics concludes the book. In the chapter on natural wealth the Corrales, Cuñapiru, and Zapucaya goldfields are briefly described, and the occurrence of silver, copper, iron, and other metals is referred to. The volume will prove of much interest to anyone wishing to obtain a general idea of the comparatively little known country.

Technical Analysis of Brass and the Non-Ferrous Alloys. By William Benham Price and Richard K. Meade. John Wiley & Son, New York, 1911. 267 pp. Price $2 net. For sale by the *Mining and Scientific Press.*

This volume is better than its promise, for in addition to methods for the analysis of brass and other non-ferrous alloys an excellent discussion of such alloys and their uses is given. The analysis of such products is a matter of special knowledge and one not easily available to the majority of analytical chemists. In the making of alloys the addition of small amounts of certain elements has a marked effect upon the properties of the resulting product, and only a refined analysis is of any service, therefore, in the judgment of composition. By gathering in so convenient form the accepted methods of procedure Messrs. Price and Meade have conduced to a higher standard of work, and their manual will be of much service. An excellent feature of the book is the devoting of over one hundred pages to applied examples of the analysis of various alloys. To many this will be the most serviceable feature of the volume, and the comprehending of general methods of work is usually much easier than their application to the determination of special cases. The book is likely to prove a most welcome one, therefore.

Catalogues Received

EDITORIAL

COPPER prices have advanced, which, together with the unexpected decrease in the surplus on November 1, is welcome news to producers.

NIPISSING continues to be a steady producer of a little less than 450,000 ounces of silver per month, and exhibits the fact that silver mining, though unobtrusive, is yet important.

RECORDS of more than one kind have been made at the Panama Canal, and a lasting one will have been established if, as now seems probable, the work of construction will be completed 18 months before the date first set, and within the estimated cost.

KATALLA is a promising oilfield. The Amalgamated Company, which acquired the holdings of the former English company, now has five wells producing, and others are being drilled. A small refinery at Katalla is producing kerosene and gasoline for the local market, and supplies a growing demand.

ILLINOIS has produced more coal than any other State except Pennsylvania; the total tonnage since 1883, when coal mining first began in the State, being 790,333,235 short tons, according to the United States Geological Survey. Last year the production was 45,900,246 tons and the State stood third, Pennsylvania producing 235,006,762 and West Virginia 61,671,019 tons.

UNCERTAINTY seems the foremost characteristic of the industrial situation. One court decision in corporation cases is hailed by the iconoclasts, the next by the conservatives. The American Tobacco decree strengthens the hopes of the latter. And when both sides are alternately pleased and disappointed it is evident that the courts must be hewing pretty close to the line.

CAMP BIRD has been a great mine, and, though it has passed its zenith, is still great. During the year ended April 30, 1911, a net recovery of $1,676,065 was made from 79,186 tons of ore at an operating profit of £267,689, and dividends amounting to £220,000 were paid. The ore reserve is now less than in any previous year, and the Santa Gertrudis is expected to take up the dividend record of its predecessor.

ALASKA'S citizens have united to effectively present their views at the coming session of Congress, and a committee has been appointed to make arrangements for a general convention to be held at some point on the coast in the near future. This is as it should be, and the sentiment of the preliminary meeting that local jealousy must not be allowed to stand in the way of the larger good of all Alaska augurs well for the outcome.

MOTOR-CAR service from Kalgan to Ku-Luen across the Mongolian desert will soon be available, as, according to recent reports from China, the Military Council has already purchased the cars. The automobile has already shown its effectiveness in desert travel in Nevada, and that the Mongolian deserts are not beyond its powers was demonstrated in the Peking to Paris road race. The expedited service is expected to materially aid in the government of the province, which is now inclined to be somewhat out of hand. The Mongol Princes, though primitive in their manner of living, are not unaware of the comforts of civilization, one of them having purchased, upon a recent visit to a treaty port, the entire stock of thermos bottles in the city.

THE SAN JUAN DISTRICT is properly elated over an offer made by the Telluride Power Company to supply electric power for prospecting purposes at half the rate charged operating companies upon 1000-horse-power contracts. This is not only a generous offer, it is also good business. The low rate probably does not involve an operating loss to the power company, and will serve to develop mines that will be profitable consumers. The Colorado gentlemen are on the right tack.

MUCH surprise was created by the recent announcement that three American cardinals would be appointed by the papal consistory to be held on November 27. The impression has been rife that so long as Cardinal Gibbons lived, no additional American cardinals would be appointed. Though the United States is a stronghold of the Roman Church it has never been adequately represented in the college of cardinals, and the announcement is therefore as pleasing as it was unexpected.

PENSION SYSTEMS are becoming more popular in all countries, a notable recent accession to the list in the United States being the gift, on November 1, by J. Ogden Armour, of $1,000,000 to establish a pension system for the employees of Armour & Company. After reaching 57 years of age employees who have served 20 years may be pensioned, while women may retire at 50 years. *En passant*, it would be interesting to know whether the donor regarded 7 years as the average discount to which woman's age is subject.

POSTAL SAVINGS BANKS were hailed with much acclaim at the time of their establishment, and the recent sale of $2\frac{1}{2}$ per cent postal savings bonds, into which deposits are convertible at par, at $92\frac{1}{2}$, comes as something of a shock. The extraordinary discount is attributed to defects in the law establishing the service, and the matter will be investigated, with a view to recommending changes in legislation. It is interesting to note also that a monetary commission recently met in Chicago to codify the national banking laws and to recommend needed legislation to Congress.

WAR, even with the modern improvements, apparently does not differ materially from General Sherman's description of it. The Turkish minister at Washington has lodged a protest with the Government of the United States against Italian methods of warfare in Tripoli. At the same time reports of massacres in Nanking and Hankow are received from the Orient. Reports of this character are usually grossly exaggerated, but nothing is clearer than that when men go to war the elemental savage comes as strongly to the fore in the twentieth century as in the fourteenth.

MINING ENGINEERS in Los Angeles are making commendable efforts to organize a local section of the American Institute of Mining Engineers, with club rooms in a convenient neighborhood. Every such effort should be warmly seconded. The gradual growth of society has, in America, tended to minimize opportunity for social intercourse, and the anecdote of the father who, by special appointment, saw his infant son once before sailing for Europe, has more than humor in it. We are much poorer from the lack of what is too often regarded as 'idle talk,' and anything which tends to promote good fellowship among engineers and intercourse upon other planes than those of business is for the real good of all.

POLITICAL prospects are of universal interest, following the recent elections. Prophets and prognosticators find room for much difference of opinion, as the straws do not all point in the same direction. The lack of strength shown by Woodrow Wilson in his home State seems to indicate that he cannot be relied upon as so strong a Democratic candidate as was once hoped. Apparently neither a paramount issue nor an especially promising candidate has as yet been brought forward. That there is widespread dissatisfaction with the present administration is indubitable; there is a general feeling that the ship of State has often been steered by invisible hands, and ever since the days when men lived in caves they have dreaded the unseen. Theodore Roosevelt conducted affairs of state with a high hand that aroused resentment in many quarters, but gave rise to the satisfactory feeling that matters were in the hands of a vigorous and alert leader who might be mistaken but who was not likely to be imposed upon. The industrial and economic upheaval through which we are now passing is of vital importance; an equally strong though less erratic leader is greatly to be desired. Will he be found?

Conservation of Oil Resources

Oil resources and their conservation are elsewhere discussed by Mr. M. L. Requa, who, as might be expected, illumines the subject with the lamp of knowledge. Reckless depletion of a supply that is not inexhaustible in order to reap quick profits has not always received the condemnation it deserves, and the spectacular features of a Lake View or Potrero 'gusher' serve to obscure the deplorable and uncontrollable waste which they represent. In calling attention to the necessity for restraint and conservation, by private initiative or by governmental control, Mr. Requa performs a service to the industry that should meet with universal support.

Mr. Requa is naturally partial to oil, and, though commending his deductions, yet it is also possible to consider the power-fuel situation from another viewpoint. We have previously drawn attention to factors which militate against the universal adoption of oil as a source of power. As pointed out by Mr. Requa, oil at 30 cents per barrel at the well is approximately on a par with coal at $1.10 per long ton at the mine, the average for bituminous coal in the United States. Obviously, then, the critical factor is transportation, since the basal prices are equal. The field is an open one, oil having the advantage of convenience in use, against which must be set the special equipment necessary for its utilization, the possibility of an eventual failure of the supply, and, in the case of steamships, the fact that it is not obtainable in every port. Nor can oil ever completely displace coal, any more than the automobile has been able to displace the horse; there is room for both, each in its proper field. The high transportation costs, which now place coal at a disadvantage, seem more susceptible of decrease than the cost of production and transportation of oil. The battle will always be fought upon the issue of cost per horse-power hour, with lesser advantages and disadvantages upon either side.

Is 'Cheap' Labor Economical

Certain topics seem destined, from their nature, to perpetually furnish themes for never-settled discussion. One of these is the advantage derived from the use of so-called 'cheap' labor, which is introduced by the author of the interesting review of the Gold Coast, appearing elsewhere. Cheap labor is usually taken to mean unskilled, in the most elemental use of the word, labor, such as that commonly available in abundant supply wherever the white man comes into contact with native tribes whose plane of civilization is low, though sometimes the term is more loosely used to include labor obtainable at a low wage yet possessed of much skill, either native or acquired. In any discussion of the subject the two classes should be sharply distinguished, for generalizations which cover the first class are obviously incorrect when applied to the second. The characteristics of a Japanese carpenter and a Chinese mechanic cannot be grouped with those of a bushman. The question is one that should not require overmuch discussion to elicit exact information, for the amount of useful work obtained from a 'cheap' laborer in return for his daily wage apparently should be susceptible of direct measurement. Actually, however, the output of a laborer is not amenable to a brake test, but must usually be estimated, thereby introducing the fallible element of judgment. Furthermore, the usefulness of a laborer is not capable of determination in the simple terms of horsepower, but includes such elusive terms as teachableness, initiative, docility, endurance, and loyalty, to mention but a few. It is clear that the degree in which these are exhibited will vary not only with the race and the individual, but also with the character and personality of the employer and 'boss.' This alone would serve to explain the wide divergence of opinion among engineers as to the worth of a given race.

The Koreans, for example, are frequently referred to as the best type of native miner. An examination into their character discloses that they are hardy and industrious, as tractable and teachable as children, and with a certain predisposition for mining work engendered by centuries of operation by native methods. The Japanese, on the other hand, are of a more intractable disposition, having acquired in a feudal type of civilization a high-spirited and resilient temperament that is less satisfactory for unskilled labor, but capable of immensely better results where the element of skill is involved. Between the two, and combining many of the good elements of both, is the Chinese laborer. His chief drawbacks are an inbred conservatism, which makes alteration in methods employed difficult, and a tendency to clannishness which is often more effective than trade unionism. This can be easily counteracted by forming gangs of men from different provinces, as they then will not 'stick together.' In the case of a Chinese laborer there can be no doubt that his cheap labor is economical. It may even be put upon a fuel basis: the cost of feeding a Chinese laborer in China may be given as 5 cents per day, regarding this as a fuel cost, the human machine is decidedly effective as compared with any possible application of machinery at the prevailing cost of fuel. It must be remembered that there is no interest and depreciation upon a coolie, and no amortization charges are necessary. Over against this must be set the fact that certain tasks are impossible of performance by any possible aggregation of human units. A lead disk with attached ropes makes a fairly effective steam-roller when welded by a dozen active coolies, but no human aggregate could perform the work of a rail-mill, to name but one of the many types of specialized machinery to perform special tasks. There are certain tasks, therefore, in the performance of which human labor, even at minimal prices, could not be economical, but this does not nullify the advantage derivable in other cases. The problem is obviously not one capable of being treated in sweeping generalizations. Race characteristics, working conditions, the effectiveness of training and supervision, and the task to be performed are all critical factors, and must be carefully considered. Next week we purpose to analyze in detail the characteristics of Chinese labor, as exhibited in the Orient, and our readers are cordially invited to make use of our columns to record their experience with and opinion of other types of native labor.

Potash

Potash has been the exciting cause of no little interest recently, but, as is often the case when technical matters are discussed by the non-technical press, much that is misleading has been put forth. A recent editorial in a leading daily journal is entitled, 'Potash is Better Than Gold,' which is as rational as to say that coal is better than custard. The facts of the matter are, briefly, that potash, like nitrogen, has always been a source of worry in the effort to obtain an adequate supply. The reason for this is much the same in both cases; potash salts and nitrates are very easily soluble, and therefore the leaching action of the rains upon the earth's crust have a tendency to dissolve them out and carry them away. This is further complicated by the instability of the nitrates, leading to their decomposition; on the other hand, the potassium which existed as an original constituent of the earth's crust tends, during the chemical changes attendant upon sub-aerial metamorphism, to lock itself up in clayey minerals from which it can only slowly and with difficulty be wrested by the chemical changes accessory to the growth of vegetation. Animals derive their supply of this necessary element either by browsing upon the vegetation or by devouring animals that have already supplied themselves with potash from the plants. In order to keep up the fertility of the soil, animal waste and decayed vegetation are applied to its surface, and the efficacy of this method is shown by the fact that the abundant crops of the sandy plain comprising all central China, have for centuries been secured by just such means.

When the need of potash for manufacturing purposes was limited to soap-making and a few other simple industries, the supply was easily maintained by leaching the ashes of burned vegetation. But with the great growth of modern chemical industry the demand increased rapidly, and fortunately was met by the discovery of large deposits of potash salts near Stassfurt. These, under the wise policy of conservation adopted by the German Government, will furnish an adequate supply for many years to come. With the increasing cost of labor the expense of gathering and applying animal and vegetable waste as a fertilizer is becoming prohibitive and, in addition, the so-called 'chemcal' fertilizers, which are prepared by mixing the chemical ingredients required by plant life in the exact proportion required by the crops to which they are to be applied, are quicker-acting and produce larger crops. This is in large part responsible for the greatly increased demand. Germany, having a practical monopoly of the supply, is enabled to maintain prices at a level slightly below that at which it would be more economical to utilize the original sources of supply. The search for potash deposits in other countries is correspondingly stimulated, but the results have as yet been meagre. Reports of the discovery of 'potash ore' have usually upon investigation proved to be founded upon feldspar or pegmatite deposits, which, though containing potash, are not as yet possible sources of supply. The old method of leaching plant ashes, seaweed, for example, is still the most promising method of developing a local supply. Arid regions, such as Nevada and neighboring States, may eventually disclose deposits of potash salts of commercial value, and free the United States from dependence upon a foreign country for a supply of a necessary element, though this should be regarded as a possibility rather than a probability.

Present Conditions in the California Oilfields

By M. L. Requa

*California has, during the past two years, developed the Midway, a new and important oilfield. In it was the Lake View gusher, credited with a total production in excess of 8,000,000 bbl. Fortunately for the oil industry of the State, nothing save a crater-like opening now marks its position. The pipe is entirely worn away, and it is seriously doubted whether anything can be done to cause the well to produce again. Fortunately again, no other comparable wells have been found. Midway is noted for large wells of 500 to 2000 bbl., but these decline rapidly and in a few months yield but a few hundred barrels per day. In proved oil territory there have been many changes during the year, but the total area will probably show but small net increase. The principal increases are from extensions of the Midway field, development of the Lost Hills and Bell Ridge, and extensions of the Fullerton-Whittier field in southern California. The fresh area absolutely proved is not much in excess of 3000 acres. Recent developments at Coalinga indicate the possible extension of that field to the south, but at great depth. Coalinga is still the most northerly field of any consequence in the State. The Kettleman Hills, tested to 3500 ft., have to date brought in nothing. Much of the territory proved within the year is extremely deep and expensive to develop and to operate. This, however, is not true as regards a narrow strip in the Lost Hills and the proved tract in the Bell Ridge fields, 26 and 12 miles northwest and north, respectively, of McKittrick. In these fields it is claimed that at depths of 600 to 1200 ft., 200 to 500-bbl. wells are the rule, and the oil is 23° or higher in gravity. At the moment this territory is the most disturbing factor in the State as regards future price of oil. It is too early to predict with accuracy the possibilities of the fields.

Geological ideas as advanced by the U. S. Geological Survey[1] must now be slightly altered. The Middle Miocene deposits are now known to become more petroliferous to the south, and the fact that they dip under the plain, becoming unconformably covered by McKittrick beds, indicates the possibility of commercial oil in the latter as well as the Vaqueros sandstone, and is important. Oil has actually been found in the McKittrick formation in the Lost Hills.

Naturally the sudden increase in production caused by the developments in the Midway field has led to a large surplus. Consumption has not kept pace with production, and it is highly improbable that consumption will, at any time in the future, increase as in the past few years.‘ Home markets are largely supplied, and future increase in consumption must depend upon larger population and more numerous shipments to South America. If a present daily production over 8 months ending September 1, 1911, be taken at 211,000, and the surplus at 34,500, the daily consumption amounts to 176,500 bbl., or 64,422,500 bbl. per annum. Compared with 1909, in which year consumption was 58,000,000 bbl., the increase is not large. The field price at present is approximately 30c. per barrel for fuel oil and 45c. for refining. There is no real reason why this price should not rule lower, as there are apparently some producers willing and anxious to sell at prices considerably below these figures.

Drilling is still active, although much of the work is being done by the Southern Pacific Co., which is reported to be running over 90 strings of tools. On January 1 last the number of rigs drilling was 567; on July 1, 492. For the six months the total production was 38,000,000 bbl. Consumption has not materially increased in 1911, and, on the contrary, has been falling in the past 90 days. The present amount of petroleum above the ground is approximately 40,000,000 bbl. The average daily surplus for 8 months ending August 30, 1911, was approximately 32,000 bbl. per day.

It is exceedingly to be regretted that the oil producers of California do not apparently as a whole realize the real cost of production. The older fields cannot hope to materially improve production costs, but on the contrary, as the deeper territory is drilled, and present producing wells decline, costs must inevitably advance. From territory of 2500-ft. depth total costs will approximate 30 to 35c. per barrel. For direct production, including pumping, cleaning, and pulling, 10c. per barrel may be safely assumed. For maintenance of surface equipment and rigs, 4c. is conservative. For exhaustion of oil land and redemption of capital, 6 to 10c. must be reckoned, and for drilling to maintain production, 12c. is not excessive. These figures total a minimum of 32c. and a maximum of 36. It is obvious that in any business where the risk is as large as in drilling oil wells, the profit should be in direct proportion to the risk. Under existing conditions in California, this is most emphatically not true.

Recent agitation that has brought about the dissolution of the Standard Oil Co. has in no way benefited the small producer. On the contrary, the situation has, if anything, been rendered more acute. Because of its self-contained character—that is, being at once a producer, transporter, refiner, and marketer—the Standard Oil Co. is able to earn a profit where the small producer is confronted with loss. Regulating prices by agreement, even within modest limits, is apparently today criminal. Because of this it is not possible to reach any agreement with the great factor in the California oil industry, and the Standard is exerting a stronger and stronger domination while the small producer is getting deeper and deeper into the mire. The utter failure of 'trust-busting', so far as commercial relief for California oil producers is concerned, is self-evident. It would be much more to the point if conditions were frankly faced as they exist, and regulation of output and prices permitted, if necessary, under Government supervision. What is being aimed at might be accomplished in that way. It is certainly not being accomplished by the present absurd methods. The Standard Oil Co. of California can quite as effectively dominate the field as ever did the parent company. Unless the country turns anarchist, confiscates property, and ignores vested rights, there is absolutely no way of curing the trouble save by pools and agreements recognized and encouraged by law. What is true of the Standard, as to cost of doing business, will apply, though in less degree, to the Union Oil Co., and to the Associated Oil Co. in still less degree since the latter is not in the refining business. To the small producer who depends for his profit on taking the oil from the ground and selling it to the transporting and marketing companies, the present conditions spell ruin unless corrected in the near future.

The waste of oil is appalling. Brought to the surface, it is allowed to lie for months in open earthen sumps. Storage tanks of steel, concrete, and earth are full to overflowing, and yet the daily surplus of 31,000 to 51,000 bbl. accumulates and is in part dissipated by evaporation. Probably not less than 4,000,000 bbl., and possibly double this amount, was lost last year by seepage and evaporation. This year will see quite as much similarly wasted. Much of this loss could be eliminated by agreements among the producers. Practical conservation would be along the lines of restricted production, permitting the oil to remain in its natural reservoirs underground until it can be produced and sold at a reasonable profit. To improve prices and relieve surplus, the suggestion has been made that large quantities of oil be burned. This would be an attempt to increase prices at the expense of natural resources. The mere suggestion of such a remedy for a condition that need not exist if sane conservation were effective, is suffi-

cient comment on the utter inability and ineffectiveness of theoretical cures. Thanks to existing laws, it seems that reckless squandering of resources must continue and the State be robbed of one of its greatest assets without satisfactory returns.

On the Pacific Coast of North and South America there has as yet been developed no deposit of coal equal in quality to the best Eastern, Australian, or Welsh. The cost of the non-uniform coal which is found and mined in Washington and British Columbia is much higher, as must also be similar coals awaiting development in Peru and Alaska. Excess in these coal costs and the poor quality of the article has, heretofore, not only retarded various industrial developments, but hindered manufacturing enterprises on the Pacific Coast. This condition, however, paved the way for the introduction of, great demand for, and marked success of the fuel par excellence in steam generation—California oil. A few comparative statements showing its superiority to coal in point of heat value and economy in firing boilers follow.

California oil in general use and under identical conditions gives uniform results. The evaporative power of the Pacific Coast coals varies greatly. Under horizontal boilers one pound of California oil should evaporate from 13 to 15 lb. of water. One pound of the best coal in use on the Pacific Coast will hardly exceed 9 lb., and 6 lb. is the figure for the lower grades. Taking the ratio of the two fuels in point of evaporative efficiency as 14 lb. to 8 lb., or 1.75 to 1, 1280 lb. or 3.8 bbl. of fuel oil is equivalent to one long ton or 2240 lb. of coal. In transportation the advantage in favor of cost by pipe-line is so great that the cheapest rail transportation cannot compete, although water transportation comes near doing so. Loading and unloading cost, in point of cheapness, loss from wastage and theft, and the decrease in stoking expenses, are to a high degree in favor of oil. Tests made by the A. T. & S. F. railroad,[2] extending over 30 days, with coal at $6.65 per ton and oil at $1.33 per barrel, showed a cost of 23.2c. per engine-mile with coal, and 14.4c. with oil. In this extended and practical test the gain in economy from use of oil was 38%. Geo. W. Dickie has furnished figures for a steamer of 3000 indicated horsepower steaming at 11 knots. With oil at $1 per barrel, the cost of fuel per day would be $300. In order to equal this with coal, it is necessary to have a delivered price of $4 and a fuel of 12,000 B.t.u. efficiency, when the cost becomes $288.16 per day. For coal of 10,000 B.t.u. delivered at a cost of $6 per ton, the daily fuel bill becomes $488.75. A vessel engaged in the coastwise trade between California points affords the following comparison:

Oil consumption per trip, 4000 bbl., cost	$4000
Firemen, wages and food	275
Total	$4275
Coal consumption, 1200 tons @ $4	$4800
Firemen, wages and food	1000
Total	$5800

This shows a saving of $1525 per trip in favor of oil, or, assuming two voyages a month, of $3050; a yearly saving, with 11 months operation, of $33,500. This at 6% is interest on a sum slightly under $560,000. Oil at $1 per barrel delivered on San Francisco bay is equivalent to about 65c. per barrel at the well.

The U. S. Geological Survey has estimated the probable minimum content of the known oil lands of the United States at 10,000,000,000 bbl., of which half is credited to California. The maximum was estimated at 24,500,000,000 bbl., allowing one-third for California. Personally, I believe that the maximum will unquestionably be in excess of 8,500,000,000 bbl. for California. The total production to September 1, was approximately 434,000,000 bbl., leaving a very large percentage still in the ground. It is safe to say that California oil will dominate the fuel market on the Pacific Coast during the present century and probably far into the next. Unless consumption is tremendously increased, this is undoubtedly true. These figures are, of course, only relative approximations, but are sufficiently accurate to warrant the assertion that California oil will dominate the fuel market of the Pacific at least through the present century.

Comparing California oil with Alaska coal, it is apparent that oil has complete control of the field. According to A. H. Brooks[3] Alaska coal can be landed at Puget Sound ports for approximately $4 per ton. Assuming 3½ bbl of oil to equal one ton of coal and oil at 50c. per barrel at the well, its comparative cost with coal per ton on Puget Sound would be $3.50. With oil at 75c. at the well, this cost should not exceed $4.20. At prices even in excess of this, consumers would not return to coal owing to the many indirect advantages accruing from the burning of oil. Costs at other points depend upon distance by sea. Assuming Valparaiso, Chile, as the southern, and Douglas Island, Alaska, as the northern extreme, with oil at 60c. per barrel at the well, coal must sell at $5 per ton at Valparaiso and $3.50 at Douglas Island to compete with oil in cost. This takes into consideration due allowance for interest, redemption funds, depreciation, and transportation. When the prices of oil are higher, coal still cannot compete, because the oil is so much more satisfactory. It is fair to assume that during the life of the oilfields there will be no fear of competition from coal until oil is selling at above 75c. per barrel.

LAKE VIEW WELL ON NOVEMBER 18, 1910.

Recent experiments indicate the possibility of oil being used for domestic purposes even in small dwellings. I am using it in my home for both cooking and heating, to the entire exclusion of coal, and a more recent device seems to make the first cost so small as to open the entire domestic field to oil consumption. If so, the consumption of coal will practically cease in California, and the public will cut fuel bills more than 50 per cent.

The action of the Government in withdrawing certain territory is a step in the right direction. Additional drilling at this time would benefit no one and would be an additional menace to an already overburdened situation. There is no storage so satisfactory as that afforded by the underground reservoirs from which the oil comes. It is free from cost of any kind, and seepage and evaporation are entirely eliminated. Some plan, however, should be decided upon whereby the land will become available as needed. Leasing under certain restrictions would seem to be a logical solution. At present it would be folly to open in any way this withdrawn area. Territory now producing can care for consumption for an indefinite period. As a suggestion I should say Government land should not be leased so long as oil at the well sells for less than 60 to 70c. per barrel, and that on leases so granted no new drilling should be permitted when prices rule below this figure. This would be sane and practical conservation, as it would permit production only in times of need and would conserve a great natural resource that, once exhausted, can never be replaced.

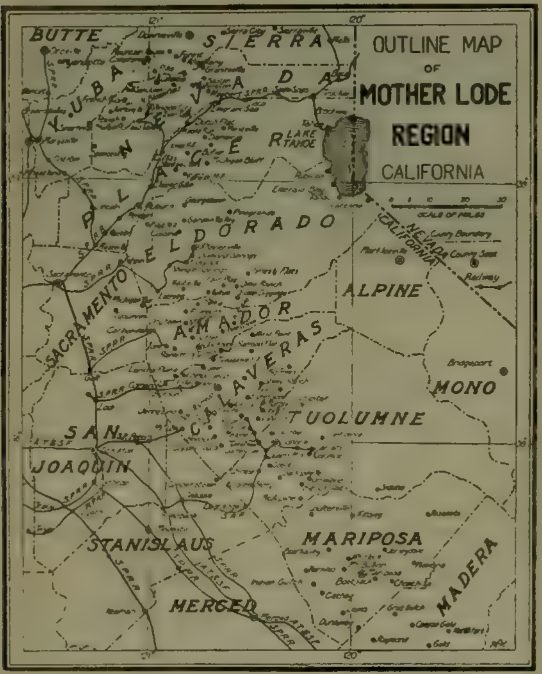
Possibilities of the Mother Lode in Depth

By William H. Storms

Recent development on the Mother lode of California has stimulated in no small degree a renewed interest in the possibilities of the great lode in depth. Investigations as to probabilities, based upon the result of the development of the noted mines of the lode, particularly as to their features and the distribution of ore-shoots in depth, are daily being made concerning property that is absolutely without development. Obviously, every mine must depend for its success upon the conditions, geological, physical, and economic, obtaining within itself. While no two mines are more than similar, yet by comparison of various mines much may be learned that is of interest, and the close observer is enabled in this way to make fairly safe deductions from the observed facts.

If there were but one or two mines developed along the line of the Mother lode it would not be defensible to assume that these were typical of all other properties, as yet undeveloped, for these one or two examples might be unfortunately chosen, for the reason that at several places on the lode large sums of money have been spent in a fruitless and, in some instances, hopeless search for profitable ore. While it is not given to anyone, no matter how experienced, to see far into the ground, yet, observing geologists and mining engineers have learned by experience that along the Mother lode there are areas where the hope of ever developing a profitable mine is slender, to say the least, while in other places the conditions are such as to invite exploration with a reasonable probability of success in the development of a valuable mine. In this the ore deposits of the Mother lode are peculiar. The generally recognized limitations of the extent of the Mother lode are from the vicinity of the old village of Bridgeport, in southern Mariposa county, and extending from there in a northwesterly direction to northern El Dorado county, a distance of about 120 miles.



If, in traveling the length of this remarkable gold-bearing belt or lode, it is found that every mine that has been largely profitable has been characterized by a noticeable set of conditions, and it is also observed that every unprofitable mine is accompanied by another set of conditions, unlike the first, it must be concluded, whether unwillingly or not, that in undeveloped ground where the conditions that have been recognized as unfortunate are present, the proposal to undertake the development of such a piece of ground would very naturally be looked upon as one extremely risky, or at any rate, as one involving a risk greater than that which might be anticipated in a locality where the physical conditions were of that type that had been recognized as being constantly associated with those mines which have been profitable.

Since certain physical conditions are known to be the accompaniment of valuable mines, a pertinent question is: What are these conditions? Briefly, every profitable ore-shoot outcropping on the Mother lode is situated either on a smooth, unbroken hill, or on a nearly level tract of land, not cut by ravines crossing its strike. In contemplating this phenomenon it is necessary to discriminate between ore-shoot and mine, for a mine may have several ore-shoots. It has been observed by myself and a number of others, that on the Mother lode no ore-shoot *at the surface* crosses a gulch or depression, though an ore-shoot outcropping on a hill, may, in its downward trend along the plane of the fissure in which the shoot occurs, pass *in depth* beneath a neighboring ravine. The only explanation I have to offer for this remarkable fact is, that gulches, ravines, and depressions at the surface are usually the physical expression of geological disturbances beneath the surface. The primary cause may have been a fault, a fold, or it may have been caused by the fact that the rocks have been somewhat softened by crushing—the result of compressive stress—and therefore more easily eroded.

Thus far, throughout the length of the Mother lode no very profitable mine has been developed in an area where the surface is cut into a series of short ridges by ravines crossing the strike of the lode. It is needless to mention the mines on the Mother lode that are characterized by the 'favorable indications,' for the reason that every largely profitable property, beginning with the Princeton, in Mariposa county, and going as far north as the Union mine in El Dorado county is, without exception, situated on a hill, or in a flat area uncut by transverse gulches, or depressions, or, if such do occur, the ore-shoots lie between the depressions. Careful investigation fails to find a mine that has been largely profitable in a locality where the lode passes through a series of short broken hills. Ore-shoots may, and do, occur in such localities, but they are short and generally do not justify the extensive development and equipment for their proper exploitation.

For years the effort has been made to determine, if possible, whether there is any uniformity or system in the distribution of ore-shoots in the great lode, but thus far the data available fail to indicate any such regularity in the distribution of the ore. However, with the careful compilation of all the data that may be obtained, it is not improbable that some very valuable information would be forthcoming. It is a fact that in most of the mines the profitable ore was entered at from 100 to 600 ft. below the surface, and in one instance, that of the main orebody of the Central Eureka mine near Sutter Creek, the shaft was sunk in the fissure to a depth of 1000 ft. before profitable ore was found. At the Union mine in El Dorado county, the first pay-shoot occurred at the surface, though there were several shoots, or zones of rich ore down to the 1700-ft. level. At the Plymouth Consolidated mines in Amador county, the first rich zone outcropped at the surface, but within a hundred feet became poor, the shaft passing through an impoverished zone to a depth of about 600 ft., where rich ore was found that continued to a depth of 1600 ft., this shoot producing, it is reported $6,500,000. The depth of the shaft is 1700 ft., the lowest level being at 1600 ft. A disastrous fire occurred in the lower levels of this property about 1889, which caused a suspension of activities there, and the mines have remained practically idle ever since, but very recently Bewick, Moreing & Co.

have taken over the property and are arranging to unwater the levels so long flooded.

At the Gover mine of the Fremont Consolidated the good ore began at the surface and according to the management, has extended to the present lowest level of the mine, at 1680 ft. (1280 ft. vertical). Sinking is in progress to 1900 ft. in the inclined shaft. This property has produced over $5,000,000. It has had a varied career, having been repeatedly closed and reopened. It is only during the past few years under the present management that the mine has had the proper equipment.

The Keystone is one of the great mines of the lode. It has produced about $17,000,000, the most of which came from veins in the black clay slate and within 800 ft. of the surface. What there may be in that part of the mine below 1000 ft. vertical is wholly problematical. It seems not improbable that there may be other great orebodies there if development is undertaken in the right direction.

The ore-shoot that made the Lincoln mine famous forty years ago outcropped at the surface and extended downward to a depth of 350 ft., where it was terminated by a fault. This particular shoot of ore has never been rediscovered, I believe.

The Wildman-Mahoney mine, which joins the Lincoln on the south, also developed an ore-shoot at the surface. The mass of ore was wide and was worked by open-cut methods. Other shoots have since been discovered and worked out in these mines. These shoots have occurred at various levels. One of the latest developments in the Wildman mine was that of a mass of ore which, starting as a narrow vein a short distance south of the Wildman shaft, widened until it measured 170 ft. across. This discovery was made on the 1400-ft. level, and as no work has been done on it elsewhere, its real extent is unknown. It is unlikely, however, that it comes to the surface. All of the ore discovered in these mines in recent years is low grade, yet if the property were equipped with a modern plant of large capacity it is more than probable that it would again become a profitable mine.

The Eureka Consolidated mine, at Sutter Creek, is one of the most noted mines on the Mother lode. It was discovered in 1850. An ore-shoot outcropped at the surface, but it was too low grade to meet the expense of operation in those days, and it was not until a depth of about 200 ft. had been reached that rich ore was found. From that time forward for many years the Eureka was a large and profitable producer. It is credited with an output of $20,000,000. It is said that the profitable ore extended to a depth of 1700 ft., where the vein was 'broken up.' Just what really took place at that level I have never been able to ascertain, as the miners who worked there whom I have met are unable to explain the condition, not understanding it themselves. Many believe that if the workings were carried to greater depth (the deepest are now about 2200 ft. below the surface), good ore would again be found, which seems not at all improbable in view of the success attending deep mining at the South Eureka and at the Kennedy and Argonaut, all lying on the lode to the southward. It is said of the Eureka that the average of the ore to a depth of 500 ft. was $10 per ton, but that much of the ore below that level went $30 per ton.

The Central Eureka joins the Eureka Consolidated on the south. A shaft was sunk on this property about 1894, to a depth of 1000 ft. before reaching any ore. Three short shoots of ore were found at that level, and these were found in greater depth to have lengthened and, finally overlapping at the ends, formed a single shoot of good ore. This shoot extended downward to the bottom of the deepest workings, nearly 3000 ft. on the incline, and yielded dividends for a long period. North of this shaft a shoot was discovered in the early days and was worked until it dipped to the north into the adjoining Badger ground. This shoot, which was low grade on the surface, is said, at a depth of 165 ft., to have milled $25 per ton, although the vein became smaller in depth.

The South Eureka mine joins the Central Eureka on the south. There is no ore known to outcrop on the surface of this property, much of which is covered with the débris of an ancient river channel, chiefly andesite cobbles and boulders. In this mine a very valuable shoot of ore was found about four years ago by cross-cutting into the foot wall. Although this has since been extensively developed, no one as yet knows where it will be found to apex. It may come to or near the surface, but it is at present impossible to say. The discovery was made on the 2750 ft. level, and development has since been carried on both above and below this level, for a distance of several hundred feet.

The Oneida mine is situated just south of the South Eureka, and has recently come into the possession of the latter company. The Oneida has been developed to a depth of 2000 ft. and has had several ore-shoots. One of those first discovered outcropped at the surface where it was 300 ft. long, and 400 ft. long at the depth of 400 ft. The average yield of this ore was stated in the Government reports to have been $17.50 per ton. Another shoot of ore was found three years ago in grading for a narrow-gauge railroad which crosses the property. Some of this ore assays over $100 per ton, and it is said to average $40, but whether this is without sorting I am unable to say. In this property the ore-shoots are not continuous, but succeed each other to the lowest level.

MT. BULLION MINE.

The Kennedy mine is one of the noted gold mines of the world, not because of its richness, but rather from the simple fact that its management has been in the hands of men sufficiently progressive to sink shafts through barren or unprofitable zones, after passing through those that had been largely profitable at higher levels, until their shafts have attained a depth greater than those of any other gold mine in America. At present the lowest level is 3450 ft. vertically below the collar of the main shaft, which is about 150 to 200 ft. lower than the outcrop of the vein on the hilltop. The shaft is over 100 ft. lower than this lowest level. The result of this enterprise on the part of the Kennedy company, which, as indicated above, has together with the other mines of the Mother lode, seen its dark days, has been to demonstrate not only that the fissures of the great lode persist in depth, but ore, as profitable as was ever found in the mine at higher levels, has been developed in the lowest levels, at depths ranging from 2500 to 3450 ft. vertically below the surface; about 4500 ft. on the vein.

KENNEDY 100-STAMP MILL.

As previously indicated, the Kennedy mine has had its vicissitudes. In its early history, during the sixties, work was confined to that portion of the vein within 700 ft. of the surface. A quartz outcrop extends along the summit of the hill, marking the course of the vein, but this outcrop of quartz is poor in gold and most of it may still be seen in place. Somewhat deeper, however, good ore was found, and the early miners exploited the vein to a depth of 300 ft. near the north shaft and 700 ft. in the vicinity of the south shaft. At these depths, and along a line connecting them, the quartz disappeared, only the fissure filled with the slaty gouge remaining. The fissure was strong and continued in its course, both in depth and longitudinally. At 950 ft. in the south shaft quartz, mixed with slate, again made its appearance in the fissure and continued for hundreds of feet, forming a valuable shoot of ore. Near the north shaft the quartz did not reappear in the fissure until a depth of about 1400 ft. had been reached, but from that level downward it continued for several hundred feet. There were two distinct shoots of ore in this part of the mine, in the ore of which there was a marked dissimilarity, though both shoots were highly profitable. In the vicinity of the 2000-ft. level the condition of the mine was far from satisfactory. There was always some ore, but much of it was too low in grade to meet the expense of mining and milling. However, on the 2100-ft. level a vein was found which was a great surprise, as it came from the foot-wall greenstone to the westward, from which direction nothing was expected. This vein proved to be profitable, and was, perhaps, the salvation of the mine, as it gave the company the much-needed courage as well as the means to continue the exploration of the vein to still greater depth. Each year the workings were advanced to increasingly greater depth, the zone of impoverishment being at length passed. Below the 2400-ft. level it was found that the ore had improved wonderfully, and it has continued to not only hold its own, but to be even better than at some of the higher levels. The fact that the Kennedy is now producing over $100,000 per month with 100 stamps, and that the ore is all practically from levels below 2500 ft. vertically from the surface, including the deepest levels, is significant of what may be anticipated on the Mother lode at great depth. I consider it the best argument in favor of the deeper development of these mines, and that others think so too is shown by the present renewed activity on the lode.

The Argonaut mine, which joins the Kennedy on the south, is practically identical with it, the fissures extending from one property into the other. In depth of its workings it is next to the Kennedy, the South Eureka being third in this respect.

The Gwin mine in Calaveras county is one of the interesting mines of the lode, having produced several millions in gold. The statement is made in the sixth report of the State Mineralogist of California, p. 32, that the value of the ore in the early history of the Gwin mine was $8 per ton in free gold, besides which there was about 2% sulphides, which were worth $100 per ton. The first ore-shoot discovered in the Gwin mine outcropped at the surface and was worked to a depth of 1500 ft. The second shoot was discovered while driving north on the 1200-ft. level, and proved to be a more important orebody than the first. It seems, from what can be learned of the early history of the mine, that the management was, if not incompetent, at least improvident, and after a number of years of successful operation the mine was closed and remained idle for a long time, being reopened in 1892-3, when a vertical shaft was commenced to reach the vein below the old workings. For several years after reaching the vein this enterprise was successful, but, like the other mines of the lode, a zone of ore too low in grade to be profitable was entered, and then the struggle for existence began, which ended in the property being once more indefinitely closed, notwithstanding a decided improvement in the value of the ore in the lowest level, at 2650 ft. vertically below the surface. I can discover no reason why, under the existing conditions, the Gwin mine with deeper development may not once more become a profitable mine.

There are no mines having a depth as great as 2000 ft. in Tuolumne county, on the Mother lode, and yet there have been some profitable mines in that part of the lode, the most noted being the Rawhide, which was successfully reopened after a long idleness. The Jumper also has made a large production, about $3,000,000, largely from masses of gold occurring at vein intersections. The workings are over 1800 ft. deep, and it is said a large body of low-grade ore has been developed in the bottom of the mine, but whether of profitable grade I am unable to state.

At Quartz, the App-Heslep is a property with an interesting history. The early Browne and Raymond reports speak in favorable terms of these mines, but they, too, have had several periods of activity and idleness. Recently this mine has had a disastrous cave-in, the cause of which is the usual one, a failure to properly fill the stopes with rock instead of depending too much on square-set timbering.

Another famous mine is the Princeton, in Mariposa county. In the early days this mine produced $4,000,000 to a depth of 600 ft. The Princeton vein occurs in clay-slate, and outcropped along the crest of a ridge. The ore-shoot was terminated at the north end by a gulch, and on the south end by a depression. This, of course, at the surface. At and near the surface the ore was too low grade to afford a profit in those early days, but a decided improvement took place at a depth of 100 to 150 ft., below which the mine was very profitable. Development was not carried far below the zone of profitable ore at that time, although the levels were extended horizontally some distance beyond it. The mine was closed and remained idle for many years, but was reopened in 1900, when it was fully equipped with hoisting and milling machinery. Since that time the output of the Princeton has been swelled to over $5,000,000. The operations of the past ten years have shown the presence of much good ore scattered here and there throughout the mine. The Princeton vein possesses many of the distinguished characteristics of Mother lode mines. It occupies a fissure of great persistence, both in vertical and horizontal extent; there are occasional branches into the walls, a feature quite common to these veins; it has its zone of rich ore, as well as those that are poor; a gouge is generally present on one wall or the other, and there are other features which stamp it as a vein of great possibilities in depth. The lowest level is at 1600 ft., equivalent to 1250 ft. vertical, a depth only about one-third as great as that of the Kennedy mine. To me this mine seems to offer every inducement for further and deeper exploration, and it is gratifying to know that active steps looking to the reopening of the Princeton mine are at present being taken, and it is my belief that if the development is carried far enough the Princeton will again become a large producer.

In reviewing the facts herein presented it may be observed that: All of the profitable mines of the Mother lode of California have had zones of profitable ore, and zones that were too low in grade to be profitable, and that these are not uniformly distributed. The upper zones of profitable ore have been found to occur at any level between the surface and 600 ft., and in one instance, that of the Central Eureka, 1000 ft., but no definite depth seems to have been established at which profitable ore has been replaced by that which is poor, nor has it been determined at what depth ore that is poor may be expected to be succeeded by that which is rich. In fact, so far as present knowledge goes, it has been learned that good ore may be found at any depth between the surface and 3450 ft. vertically below it. However, when all the available data are collected and careful comparison made it may be found that there is more regularity in the occurrence of ore-shoots on the Mother lode than a casual glance may indicate. To me it seems that proper geological conditions are of greater importance than all other considerations, and that where these are present there is every reason to anticipate the recurrence of rich ore in the fissures to a depth as great as lies within human skill and mechanical means to reach. There are so many authentic instances where a mine once profitable has been found to be so again at greater depths, that a similar result may be expected in every case where idle mines have a good record of earlier production. Moreover, in the case of undeveloped properties, where the geological and topographical conditions are favorable, the probabilities for successful development in depth may be considered as most promising, even where the ore at the surface is too low in grade to afford a profit, for some of the best mines on the lode were of this character at the surface, as has been indicated.

Precipitation of Copper From Mine Waters

By Floyd Bushnell

Although copper has been hovering around the 13c mark for the past four years, the precipitation of copper in the Butte district has not decreased as much as might have been expected. Several of the smaller and less prosperous plants on Silverbow creek on the south side have been compelled to discontinue operations, but the larger are running at full capacity.

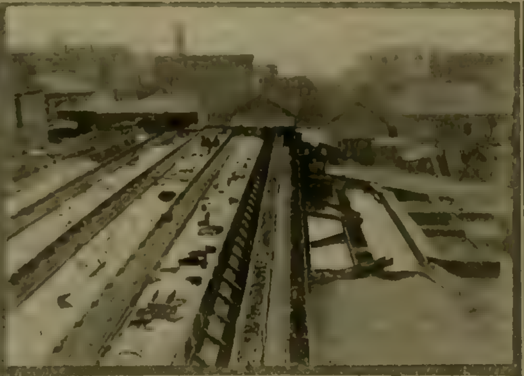
Twenty-three years ago the making of copper through the employment of mine-water was unheard of, and it is difficult to say just how much copper went to waste in the early days through failure to utilize this method. A Welshman named Morgan was the discoverer. In 1880, while living near the gulch through which ran the waters from the Anaconda and St. Lawrence mines, he noticed that tin cans thrown into the water soon disappeared, leaving a dark-red sediment in their place. He had this sediment assayed and was surprised to find it contained a large percentage of copper. Morgan died before he attained any great degree of success. Fred Miller then took up the work, and while his methods were crude compared with those of the present day, he was more successful than the discoverer. Miller dammed up the water into small ponds, into which he threw tin cans and scrap iron; after the metal disappeared he drained the ponds and scraped up the precipitate. Others became interested and encroached upon his rights, whereupon he became discouraged and quit the business.

William Ledford, in 1901, was the first to put copper precipitation on a business basis. He secured a three-year lease on the water from the St. Lawrence and Anaconda mines at a 25% royalty. Ledford was subjected to much criticism because of his so-called foolish venture, but during the life of the lease he cleared $100,000. During this lease the copper water became so strong that in a short time it corroded the pipes through which it was pumped to the surface, whereupon the companies weakened the water by passing it over iron underground. Ledford contested this on the ground that he was to have the sole right of precipitation. He sued the Anaconda company and was awarded several thousand dollars damages. After this successful venture the companies refused to give further leases, and the larger companies have since been doing their own precipitation; the Amalgamated, the Boston & Montana, Gagnon, Original, and other mines have plants at their properties. However, there are a few smaller companies that lease their copper water.

The plant at the Original mine has about the most economical system in Butte. Three men take care of 1400 linear feet of boxes. This company is the first to use the hose-washing system, which is decidedly effective. City water, under good pressure, is piped to all parts of the boxes, and at regular intervals the precipitate is washed from the half-eaten metal and from the bottom of the boxes. The precipitate is protected by means of a shelf, 2 in. from the bottom, and once it is separated from the metal, is unimpeded in its course to the tanks. This system is so arranged that the copper water may be shut off from any part of the plant. The high-grade precipitate is flushed into tanks 2 by 7 by 9 ft. in a steam-drying room. There are two tanks, each holding 21 tons and are filled several times per month.

The plants which secure their water direct from the mines and those operated on the sites of abandoned smelters have water with by far the highest copper content. The water as it comes from the mines averages from 0.04 to 0.06% copper. With the 0.06% water precipitate as high as 90% is secured, and from this it runs as low as 30% copper. Some of the operators are so fortunate in the situation of their plants that they can cause the water to

MANY SMALL PLANTS EXIST ON OLD SMELTER SITES, WHERE WATER SEEPS THROUGH TAILING AND SLAG PILES.



BOX SYSTEM AT THE ORIGINAL MINE.

COMBINATION BOX AND TOWER PLANT IN THE WINTER.

flow through the tailing heaps of abandoned plants, thereby materially increasing the copper content of the water.

There are at present two methods of precipitation, the box system and the tower system, the latter being generally conceded to be the more successful, as the towers occupy less space and the water is brought more thoroughly into contact with the iron. The box system consists of a series of troughs from 1 to 3 ft. wide and 1 ft. deep, covering a great deal of surface. The boxes are so arranged that there is a gentle incline and the water flows naturally through them. The scrap iron and tin cans are thrown into these troughs. The copper precipitate, after being washed through the many compartments, sinks to the bottom of the receiving-tank, which is cleaned out about once a month.

The tower system was introduced about eleven years ago by Huddleston & Turner. The usual tower is about 3 ft. wide, 20 ft. high, and 30 ft. long, and is partitioned off by means of floors 18 in. apart. These floors are made of 2 by 4-in. scantlings, placed 3 in. apart, running lengthwise. Tin cans and scrap iron are placed on the several floors. By means of a small pump the copper water is raised to the top of the tower, where it is distributed equally over the scrap iron. The tin cans and smaller pieces of iron are eaten away in a comparatively short time, but the larger pieces must be scraped regularly to remove the precipitate. The latter is washed to the bottom and then into tanks alongside the towers.

The operators sell their output to the smelters at 4c. less than the market quotation for copper; the shippers must pay a treatment charge of $5 per ton. The cost of making a pound of copper is estimated at between 7 and 8c., so that with the present price of copper there is not a very large profit. Theoretically a pound of tin or iron will precipitate its chemical equivalent in copper. Tin cans are used where the water is weaker, and iron and steel are sought after by those who have stronger water. A test made with the same water shows that tin cans produced a 33% copper precipitate, and iron 50%. At many of the plants one or two men do nothing but remove the paper from and punch holes in cans in order that the free passage of water may not be interfered with.

It might be thought that the plants would be compelled to close in winter, but such is not the case. The water coming in from the mines is quite warm, and the chemical action of precipitation liberates heat. The water has a greater percentage of copper in it during the winter months because there is no surface water to dilute it. As a matter of fact, almost as much copper can be made in winter as in summer. One peculiar feature of this work is that the streets and alleys of Butte are kept free of tin cans and scrap iron. Because of the increased demand for scrap iron for precipitation purposes during the past five years the price of old iron has increased from $7 to $12 and $14 per ton; $10 is the average price for a ton of tin cans. Men and boys make a living in the larger towns of the State securing material for these plants. It is hard to give the exact amount of precipitate produced in the Butte district, but a conservative operator places it at 700 tons per month. If anything, this estimate is low.

The Boston & Montana plant, at Meaderville, securing its copper water from the two Leonard mines, the West Colusa, and other properties, is one of the largest and most up to date in the district. Two flumes, 1000 ft. long and 4½ ft. wide, 800 linear feet of boxes, and four large towers are operated by this company. The towers are 100 ft. long, 30 ft. high, and 6 to 8 ft. wide. The lower towers have two electric elevators to raise the iron to the top of the towers. The precipitate is dried to 8% moisture, barreled, and shipped in 30-ton lots to Great Falls for treatment; three shipments per month is the average output. The average strength of the Boston & Montana copper water is 0.05% copper. But during the fire that raged several years ago in the underground workings of the West Colusa and other mines, the percentage of the water ran as high as 0.32%. While the water was at this great strength 90% copper precipitate was produced and the average monthly shipment of precipitate was 9 carloads. Under normal conditions the precipitate averaged 60% copper.

The charge was made in a recent issue of a mining journal that the methods employed in Butte are crude and wasteful as compared with the plants at the Rio Tinto mines, where the water runs as high as 0.2 and 0.3% copper. A comparison between the methods employed by these two camps is absurd; the water from the Rio Tinto mines, after having run through the precipitating plants, is as strong as the water coming from the Butte mines. The charge was also made that strong copper water flowed down Silverbow creek, past all the precipitating plants. Such a statement is absolutely false. An assay of the water after it passes the last precipitating plant shows the exceedingly small percentage of 0.0002 copper.

Mining at San Jose de Gracia, Sinaloa

By G. L. Sheldon

San Jose de Gracia, Mexico, is situated in the northeastern part of the district of Sinaloa, State of Sinaloa, about 70 miles northeast of Bamoa, a station on the Southern Pacific Mexican railroad system. There is a wagon-road for about one-half of the distance, by way of Bacubirito. The town is on the Alisos, commonly called San Jose de Gracia *arroya* (creek), about 12 miles above its mouth, where it empties into the Sinaloa river, at San Ignacio. The altitude at San Jose is 1300 ft. Adjoining the town on the east and southeast, is a basin, near the confluence of two or three small *arroyas* which join the Alisos just below the town. This basin has been the centre of considerable eruptive activity; the small hills and higher mountains to the north and east are highly colored, and at a distance (as one comes down the mountain to the east, on the Calabacillas trail) much resemble those of the San Juan, Colorado, except for the difference in altitude.

The rocks in the basin are chiefly andesite, extending to the east, about two miles from San Jose *arroya*. Here slates, shales, and limestone appear, and are continuous to the east to the top of the mountain (altitude 4500 ft.), which forms the State line between Sinaloa on the west and Chihuahua on the east. To the east of the divide similar rocks persist for several miles, but are cut by andesite and trachyte dikes. The town of San Jose was settled in 1828 by some Spaniards, Mexicans, and Indians from their main town or mission at Sinaloa, on the river of the same name, in the lower agricultural country. For years there had been rumors of gold in the mountains above the river. At or near the mouth of the *arroya* which empties into the San Jose just below the present town, they found a small Indian village. The Indians had some goats confined in a nearby stone corral; wishing to purchase some, the visitors went to the corral, and found it made of quartz, in which, upon examination, much free gold was to be seen. This was on or near the vein known ever since as the Mina Grande. They immediately began work and it was found to be very rich, but has never been worked below 100 ft. in depth, although it is well worthy of further exploration.

There were several other veins discovered in the near vicinity, which yielded surface pockets of rich ore. The district is much faulted and in the early days this was not understood, consequently when a fault was met work was stopped. Most of these early discoveries have only been worked to slight depth; they are owned by individuals who continue to pay the taxes, but do no work. With intelligent development no doubt some of them will prove good mines. Many of the best mining men left for California overland during the '49 to '52 gold excitement. After this, until the Diaz régime, there was not much encouragement to work the mines on account of the numerous revolutions, as both parties held up and robbed everyone who had anything; but Porfirio Diaz stopped that and made the country safe.

In 1893 Francisco Peraza found rich ore on his Jesus

Maria claim, which he had been working in a desultory manner for several years. About this time, H. H. Hughes was in charge of the Trigo silver mine, near Yeadras on the State line of Sinaloa and Chihuahua, some 50 to 60 miles east of San Jose, and, hearing of this rich find, sent for samples of the ore. The Trigo mine at that time was apparently worked out, after twenty years of continuous development, never having paid a dividend. The management was anxious to find a good mine, and finally made a deal with Peraza for the Jesus Maria for $75,000; a liberal cash payment was made, the remainder on easy terms. Mr. Hughes immediately took charge and moved some of the machinery from the Trigo mine; W. C. Wilkins was made mine superintendent. By 1895 they had a 60-ton milling plant, offices, machine-shop, laboratory, and other buildings. The mill-heads for three years averaged $65 per ton. The bullion is 700 to 750 fine. Later, E. A. H. Tays was superintendent, with Mr. Mills, of the San Fernando, Durango, mine, as manager of the property, which was known as The Anglo-Mexican company.

After having paid five millions in dividends, and worked over the tailing dump of 30,000 to 40,000 tons, said to have run $25 to $30 per ton, the company sold the property to Peraza (the former owner), and Antonio and Miguel Tarriba, for ₱27,500, in May 1902; the management believing (as one of them told me a few months later) that the mine was completely worked out, and not worth a jack-knife; also, that the vein faulted so badly it cost more than it was worth to find new orebodies. I have been reliably informed that, during the first six months after the sale to Peraza and associates, they took out $64,000 net.

During 1905 Norman T. Tracy, who was then manager for the owners, surveyed and advised a long cross-cut (500 metres) to cut the vein at a new point on a lower level. Mr. Tays, later, being called as consulting engineer, also advised it, and the vein was intersected in good ore, which was persistent. The present owners have taken out about $3,000,000 worth of ore and now have one to two years' reserve. For the past three years M. A. Newman, formerly with George Tweedy at the old Bradbury Rosario or Tajo mine, near Mazatlan, has been manager, with an efficient force of Americans directing the various departments. Mr. Newman has overhauled the entire plant and changed the method of treatment. By putting in tube-mills and cyanide tanks with mechanical agitators he has increased the saving from around 65% to better than 90%. The question of putting in a hydro-electric power-plant on the Sinaloa river was seriously considered, but it was found that it would cost in the neighborhood of $300,000. As the interest on the investment there is 1% per month, and at present there is no demand for the excess power generated, it was considered best to transform the present steam-power plant to electric, using wood for fuel. This is now packed 10 to 12 miles at a cost of ₱10 per 2000 kilometres. It would appear that in the not far distant future it may be found advisable to move the steam-plant nearer the source of the fuel supply.

The cyanide tanks were placed in front of the two-story hacienda building, erected by the Anglo-Mexican company at a cost of ₱40,000, which is 500 ft. from the mill; this was necessary, as there was no other suitable site. Everything is run by electricity, the pumps, hoist, and the lights at the mine, and all the machinery at the mill, including a small ice-plant. An old tailing pile, about 50,000 tons, has an average gold content of $12. A new plant to treat this is now practically completed. They have to be raised 50 to 60 ft. and moved horizontally over 500 ft. by an endless belt, and are then treated by an additional steam-plant in tube-mills and cyanide tanks. The treatment is expected to net $500,000. The present management, in running the 400-ft. level, below the long cross-cut, on the vein, has extended this level out under the old Anglo-Mexican company's working, but 200 ft. deeper. The Anglo-Mexican company had no ore above, but below, persistent good ore. The present company, known as the Jesus Maria Anexas, has a large territory yet undeveloped; the deepest workings are only 700 to 800 ft., and it would appear that the property should have a long, profitable life before it. With the present capacity, it has an annual production of around three-quarters of a million, nearly two-thirds of which is profit.

The only other mine on which any work has been done in recent years, or ever extensive work, is known as the Rosario. This is less than 2 miles to the north and east of the Jesus Maria and is in the slates, shales, and limestone which extend down to within ½ to ¾ mile of the Jesus Maria, which is entirely in the andesite. In the early days of the district the Rosario was known as the Los Muertos, and a small surface pocket of rich ore was taken out. In 1893 W. C. Wilkins, Manuel Flores, and Mr. Parker located it, and in 1894 they sold the property to Antonio Echavarria for ₱5000. The vein, which was well defined on the surface, ran only $4 to $6 per ton. Don Antonio was an intelligent, practical miner, and much of the data herein was given to me by him. He ran a short cross-cut and intersected the old Los Muertos vein at about 100 ft. in depth, finding 7 ft. of bonanza ore. By June 1896, he had a complete 30-stamp mill all paid for, and for several years the annual production was better than one-half million. The tailing, which ran down the creek and was lost, assayed $12 to $20. They developed several veins by adits at good depth that gave very good ore. There are 8 to 10 other veins on the property as yet undeveloped that make equally as good a surface showing as the one developed. For several years the property has been in litigation, and for the past two years idle, but it is now generally understood that the former owners, which include Peraza and the Tarriba brothers, of the Jesus Maria company, have practically settled all litigation and in the near future will reopen the mine.

I believe if the district were in the United States, that within three years it would be producing from one-half to a million dollars per month. The present owners of the developed properties and many of the undeveloped ones are Mexicans; the two principal owners have been in Paris for the past two years, trying to spend their dividends from the Jesus Maria. There is no work whatever being done outside of the Jesus Maria mine. It is interesting to note there are working in the Jesus Maria mine three blind Mexican miners. Two lost their sight in a powder explosion; the other, a younger man, has learned by practice since he became blind to use the hammer and drill. They are led to the mine each morning and home each evening by a small boy, and the shift-boss takes them wherever he wants them to work, and points their holes for them. By taking a drill and placing their hands on either end of the drill, he gives them the place and direction of the holes; they put in a regular shift, accomplishing as much and receiving the same pay as other miners, working alone single-handed; their holes are loaded and fired by others. Formerly the company allowed them 25c. extra per day for the candles which they do not use, but this has lately been discontinued. They are as happy and contented as any of the other workmen.

During the late political disturbance, the *Insurrectos* held up the management for the bullion on hand and placed them in jail until they turned over $41,500; the mine was shut down, but after the railroad commenced operating again, so supplies could be obtained, it has been running continuously. The two generals in command of the *Insurrectos* that took the bullion, in June were placed in jail in Culiacan, by the orders of higher officers; one-half of the bullion was immediately returned, with a promise of returning the rest as soon as possible. San Jose is on the western edge of a gold district that extends east and north to Guadalupe y Calvo in Chihuahua, embracing all the southwestern portion of the Guadalupe y Calvo district, and extending into a portion of the Sinaloa and Mocorito districts in the State of Sinaloa. The Calabacillas mine, with a production of two and a half to three million, is in this area; also the La Cumbre de San Manuel mine, which has recently been sold to S. C. Dickinson, representing English capital, for $530,000. This gold district is one of the best in northern Mexico, but is little developed.

Tin Dredging in Alaska

By H. G. PEAKE

In 1900 and 1901 placer miners, who had traveled up the coast from Nome, started work on Buck creek in the Port Clarence mining district of Alaska. The gold was saved with difficulty, owing to the fact that it was heavily covered with some coating substance, making amalgamation impossible, and the riffles were rapidly filled up with an unknown heavy material, making the saving of gold still more difficult. The miners did not detect the true nature of this heavy substance until members of the U. S. Geological Survey came through the district and pronounced it cassiterite. On assaying, it was found to contain 68% tin. Several companies were subsequently formed for the exploitation of this deposit, and their failure has cast a certain amount of discredit on this field. In 1905 and 1906 the American Tin Mining Co. secured, by purchase and location, most of the claims on Buck creek; the remainder was secured later. Buck creek is fourteen miles inland from York, the nearest port, and extends from the junction of two smaller streams for a distance of about 3½ miles before emptying into Grouse creek, which empties in the Arctic Ocean. This company later took in an excavator of French design, which was set up and operated for five days, then abandoned, as it was found that it was unsuitable for the work. The crew were then put to work shoveling into sluice-boxes, and during the remainder of the season 37 tons of concentrate, which averaged 68% tin, was recovered. During the past five years this company, in performing its assessment work, has taken out enough tin each season to pay the expenses of sending up the crews, together with their wages, and all other cost of the work. The deposit on this creek has been examined by mining engineers, and was on one occasion surveyed and mapped and a thorough test made with a Keystone drill. This test showed a tin content high enough to warrant working the property, if a satisfactory method could be found.

On January 18, 1911, W. W. Johnson, of San Francisco, leased the property of the American Tin Mining Co. on a royalty basis; subsequently he organized the York Dredging Co. This company, after carefully looking into the matter, placed an order for a specially-designed dredge, suitable for operation in the shallow deposits and under the conditions in the district. The order for the dredge was placed with the Union Construction Co. on May 26, they agreeing to complete it in such time that a test run could be made this season. The machinery was shipped from San Francisco, on June 24, and at Seattle the lumber for the hull, which had previously been framed and fitted together ready for erection, was loaded on the same vessel. By special arrangement with the steamship company, this vessel made a trip to York, the nearest port. The roadstead at this port is very shallow, and the vessels are obliged to anchor some three or four miles from shore, where all freight is transferred to lighters, on which it is carried as near the shore as possible. From the lighters it is transferred to shore by wagons. From York to the site on Buck creek, where the dredge was to be built, it was necessary to make a wagon-road. This was done by cleaning out the bed of the Anikovik river where necessary, and by graveling about two miles over a low divide to the head of Grouse creek, the bed of which was also cleaned out. Work was started on the road June 15, and a camp was established at the dredge site at the same time. The vessel carrying the dredge machinery and lumber reached Nome on August 3. Here the construction crew, together with extra teams for hauling, were picked up and taken to York. Construction work was commenced on August 7 and the dredge was completed and ready for operation on September 6. Unfortunately, a severe storm washed out a portion of the dam below the dredge, and it was necessary to rebuild this before operations could be commenced.

This machine has 2½-cu. ft. open-connected buckets. The hull is 30 by 60 by 6½ ft., and 75,000 ft. of lumber was used in its construction. The dredge is provided with a revolving screen for washing the material. This has 3-in. perforations and the water-supply is furnished by a 10-in. centrifugal pump, designed to deliver 3000 gal. per minute against a head of 40 ft. The material passing through the perforations in the screen is delivered into either one of two sluices, which extend from a point at the centre of the dredge, 35 ft. beyond the stern. On account of the bulk of material to be recovered, provision was made so that one sluice could be cleaned up while the other was in use. The material passing through the end of the screen is delivered by means of a chute to a picking-belt, which delivers the rejections at a point about 10 ft. beyond the stern of the dredge. Occasionally cassiterite boulders weighing from 5 to 40 lb. are found. These are recovered on the picking belt by Eskimos. Between the two sluices and extending from their outer end to the upper, another conveyor was installed so that the concentrate could be shoveled from the sluice being cleaned up, directly upon it. This belt delivers its material into a hopper on the dredge, whence it is taken and sacked for shipment. The dredge is operated by means of gasoline or distillate engines, of which two are provided, one for driving the pump and one for the main drive, winch, screen, and conveyors.

The dredge started operation on September 10 and was run continuously until October 15. It has handled from 800 to 1000 cu. yd. per day and has recovered 2.85 short tons of concentrate for each operating day. This installation was considered by well informed men as more or less experimental, but all agreed that dredging was the best method for handling the deposit, and the results have proved conclusively that this was correct. So far as I am informed, this is the first placer-mining dredge for the recovery of placer tin that has been installed and successfully operated on the western hemisphere. Its work would seem to warrant further exploration of this field.

Phosphate Deposits

When the coal deposits of Pennsylvania, West Virginia, and other States of the Appalachian region were being formed, many millions of years ago, in the Carboniferous age, there were also being accumulated in the Rocky Mountain region enormous mineral deposits which are of a widely different character, but which may nevertheless play a part in the industrial development of the United States comparable even to that of coal. These are the phosphate deposits of Wyoming, Utah, Idaho, and Montana, which are now known to contain hundreds of millions of tons of phosphate rock, constituting a most important artificial fertilizer. Until recently it had been generally assumed that the phosphate deposits of South Carolina, Florida, and Tennessee afforded an 'inexhaustible' supply, but recent estimates by the U. S. Geological Survey show that at the present rate of increase in phosphate mining these deposits are likely to be exhausted within a generation.

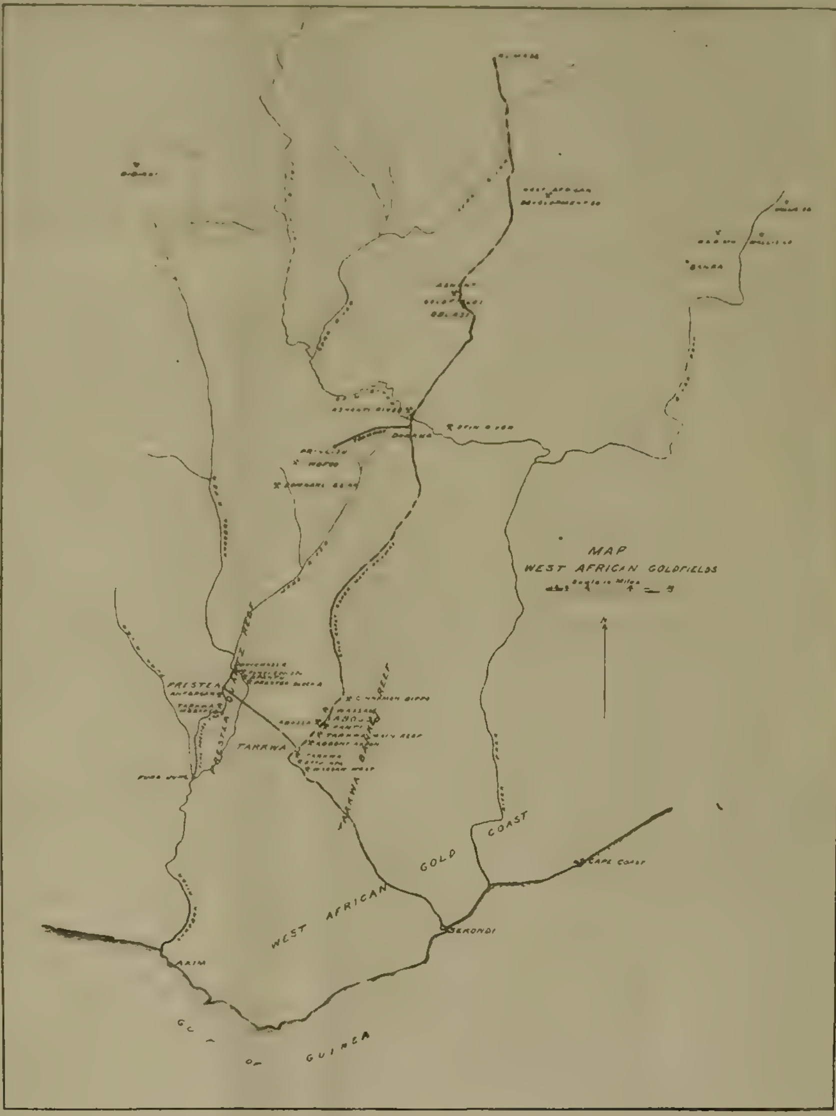
The discovery of the Western phosphate beds, therefore, constituted a most important find, and though the first reconnaissance of these deposits by the Geological Survey showed their considerable extent, the more detailed study and exploration, with additional discoveries made by the Survey during the last three years, have shown that the field is probably the greatest in the world. Recent geologic study of the phosphate-bearing strata indicate the probably still greater extension of the phosphate area. The northernmost portion of the beds first discovered was in Wyoming, but an outcrop of the same character and in the same geologic formation was found last year in Montana, some 160 miles farther north, so that Survey geologists believe that workable phosphate beds may be found in many other places. Phosphate rock usually sells in the markets upon a basis of about 60c. per unit per cent of available phosphoric acid, though high-grade phosphates from Eastern deposits bring as much as $4 to $5 per ton f.o.b. mine.

Gold Coast Mines, West Africa

*The Gold Coast is contained between 5 and 10 north latitude and 3° 7′ west to 1° 14′ east of Greenwich, including Ashanti and the Northern Territories. The population of the Colony and the Protectorate may be set down at 2¼ millions, but cannot be stated definitely, even when the census of 1911 is made known. The first records of gold from the Coast date back to about 450 years ago, when the Portuguese obtained, by trading, considerable quantities of gold from a port on the Gold Coast, which they named El Mina (signifying the mine). Subsequent trading stations were established by the Portuguese, Dutch, English, Germans, and Danish. The operations of these various companies were all confined to the coast, but considerable quantities of gold reached the hands of the traders, principally from the hinterland. In the year 1872 the whole of the rights to the territory now known as the Gold Coast was acquired by the British, and this fact led to the first Ashanti war. As the Ashantis had generally conducted their trade with the coast through the Dutch, they feared that the British would try to deprive them of their trade connection with the seaboard. The British operations of this war were intrusted to the command of Sir Garnet Wolseley, and were wholly successful, as were also the wars of 1896 and 1900, in spite of the dense jungle which intervened between Cape Coast Castle and Coomassie, a distance by road of 186 miles. Up to the time of the subjugation of the Ashantis by the British this powerful combination of tribes maintained a complete control by force of arms, of nearly the whole of the tribes of the Gold Coast Colony, between Ashanti and the sea, and all trade with the hinterland was only carried on by their permission.

The constant demand for gold by the many trading stations on the coast resulted in extensive washing operations being conducted by native tribes, who, being slaves, were compelled to obey the demands of their taskmasters, and pay a yearly tribute in gold. In the earlier days most gold was obtained by panning the gravel from the many streams, and by hand-crushing the outcrops of quartz reefs, but later the auriferous conglomerates, which are now known under the name of banket, were discovered by natives, who, in their search for gold, sunk numerous pits along the outcrop at close intervals. The work of sinking the pits and of mining the conglomerate was performed by men, but the ore, after being raised to the surface, was taken to the creeks, disintegrated between stones, and panned by the women. The natives had no idea of driving from one hole to another, and when they reached the conglomerate beds (always by circular shafts 20 to 24 in. diam., and sometimes 40 or 50 ft. deep) they would gouge the ore for a few inches all around the bottom, and then proceed to sink another shaft, so that in places the ground was literally honey-combed.

Pierre Bonnat had been taken captive by the Ashantis, and remained a prisoner with them for several years, during which time he often heard the natives speak of the valuable deposits at Taquah. On regaining his liberty, some time in the early seventies, he proceeded to the Wassau district, in which the Taquah belt is situated, and obtained from the local chiefs two concessions, one at Taquah, the other at Abosso, these being about six miles apart. When it is considered that the whole of the country is covered by a thick jungle which makes an examination of the surface a matter of the greatest difficulty, it is an extraordinary fact that the areas taken up by M. Bonnat are today the most valuable ones on this line of auriferous country. M. Bonnat after obtaining the concessions proceeded to France, and was successful in obtaining the flotation of his properties and securing the necessary capital to enable him to develop and exploit his concessions. In spite of the great difficulties of transport, the unhealthfulness of the country, the denseness of the jungle, and the heavy rains, for which the coast is noted, M. Bonnat succeeded in opening up the mines and equipping them with hoisting and treatment plants; but although the ore mined and treated was of fairly high grade, the cost of mining and treatment, owing to the



---

*Abstract from *The Mining and Engineering Review.*

difficulties mentioned above, was so great that the company was compelled to cease operations. Some of the difficulties of transport will be understood when it is mentioned that, though river transport was utilized as much as possible, in many cases the machinery had to be transported on natives' heads over wretched jungle paths. Most of the machinery, therefore, had to be made in sections. In this respect the Bibiani mine has been laboring under a heavy burden through having the whole of the plant sectionalized so that it could be carried by natives from the railway station at Dunkwa to the mine, a distance of 70 miles.

The first noteworthy mining operations by British companies were carried out during the latter seventies, but, owing to the extremely insalubrious nature of the climate, these operations were limited. In 1900, however, quite a boom was created in West African mines, and many ventures, chiefly of a wild-cat nature, were floated on the London market for large sums. The collapse of the boom a year or two later left few mines in actual operation. Those on the Taquah belt which continued working are the Wassau gold mine, Abosso gold mine, Abbontiakoon and Taquah Exploration mines. On the quartz belt the only mines that were able to survive the slump were the Prestea Block A and Broomassie mines in the southern part, and Ashanti Gold Fields Corporation and Bibiani mines in the northern part of the colony. The result, however, of several years' working was the depletion of high-grade ore reserves and the gradual extinction of the capital of most of the various companies, owing to the extremely high costs of mining. All skilled labor required has to be imported at considerable expense and high wages, while the actual manual labor is entrusted to the natives. The London directors at their annual meeting of shareholders like to expatiate on the cheap (?) labor of the Gold Coast, but many years of experience has fully established the fact that native labor, though nominally cheap, is really most expensive, even when properly supervised, but it is an unfortunate fact that supervision on the West Coast has generally been of a most perfunctory character. Things continued in this state until the year 1908, when several mining engineers from Western Australia, who were placed in charge of some of the mines, became convinced of the fact that mining and treatment by careful management could be carried out at a cost that would leave a fair margin for the shareholder. Representations being made in the proper quarter resulted in large sums being invested in the industry, principally by the big South African companies, notably the Consolidated Gold Fields of South Africa, and the infusion of this new blood resulted in the boomlet of 1909.

Gold is generally obtained on the coast from two parallel auriferous belts, the principal one being the Taquah banket belt, on which workings are at present being carried out over a length of 20 miles from Eduapriem on the southwest to Chida in the northeast. To the north of Chida there is a break of a few miles, in which very little banket has as yet been discovered; beyond this large deposits of banket (said to be of a profitable nature) have been opened up by the Wallis Syndicate, Ambroso Syndicate, and other prospectors for a distance of several miles along the outcrop. The quartz belt lies 15 miles west of the Taquah banket, and extends parallel in a southwesterly and northwesterly direction. Gold in this latter belt is mostly contained in quartz reefs, in a fissure of the graphitic schists, which are mostly found associated with auriferous quartz reefs. These may be said to extend from the seaboard near Axim far into Ashanti. If one were to judge by the magnificent reports gathered by the many eminent (?) engineers, which have been put in the papers during the last two years, the Gold Coast must be a happy hunting ground for those in search of the precious metal: but the fact remains that, though a considerable number of mines offer a fair opportunity for the profitable employment of capital, the greater portion of the reefs, whether banket or quartz, are not by any means of a profitable character, so far as they have been proved by workings along the outcrop. As a matter of fact, the known profitable areas do not comprise one-sixth of the line of reef, on what is known as the banket belt; while on the Prestea quartz range the lengths of outcrop that offer inducements to prospecting companies are comprised between Anfargah on the southwest and Broomassie on the northeast, a distance of probably five miles, though prospecting and mine development are being carried out for about another twelve miles northeast of Broomassie, and five or six miles southwest of Anfargah. In Ashanti mining operations have mostly been confined to the quartz belt, which is believed by some authorities (on rather slender evidence) to be a continuation of the Prestea goldfield. During the early part of the present century an immense amount of speculation took place in Ashanti, but, owing to inadequate returns, the field was gradually limited to work on the Ashanti Gold Fields Corporation, Akrokerri, and the small property known as the Ashanti Quartzite. In the year 1909, however, owing to the depletion of its ore reserves and to the fact that development work failed to disclose any further bodies of ore, the Akrokerri mine ceased operations and disposed of its machinery.

Progress in Zinc Smelting in 1910

By C. E. Siebenthal

*The expense of the manual labor necessary in retort zinc smelting and the losses incident to the lack of continuity in that process have stimulated metallurgists to invent mechanical charging devices and to design forms of furnace in which the smelting operation should be continuous.

The Saeger cleaning and charging machines, in use in the Silesian zinc works of Georg von Giesche's Heirs, consist of steel trucks operated by electricity upon tracks parallel to the face of the furnace. Mounted upon each truck in alignment with the sloping retorts are as many banks of screw conveyors as there are banks of retorts in the furnace, and from three to eight conveyors in each bank. After the condensers are removed, the cleaning machine withdraws the residues by inserting the screw conveyor into the retort; then follows the charging machine in which similar conveyors push the charge into the retort. The advantages of the machines are summed up as follows: Saving of half the labor charge; shortening of the injurious cooling-off period while cleaning and charging the furnaces, thereby increasing the time for distillation and consequently the yield; and lastly, more healthful conditions of work.

The Wettengel rotatable furnace is designed to save time and trouble in charging and cleaning the retorts. These are arranged in batteries in a revolving steel shell. They are turned upright beneath individual hoppers for charging, are revolved into horizontal position for distillation, and lastly are turned downward for discharging the residue. After re-charging they are turned to the horizontal, 180° from the position of first distillation. By thus alternating the top and the bottom of the retort its life is presumably doubled and the residue does not accumulate on one side. A small Wettengel furnace was in operation during 1910 at the works of the American Zinc, Lead & Smelting Co., at Caney, Kansas, but the tests are not yet concluded and results are not available.

The Hughes revolving furnace consists of a rotary retort held in place in a rotary shell or combustion chamber. A stack ore-hopper feeds continuously into the upper end of the gently sloping retort, which discharges both zinc vapor and residue into a stationary cylindrical condenser at the lower end. Both the size and the temperature of the condenser are controllable. The waste heat of condensation is carried through the hopper, preheating the charge, which arrives at the retort with a temperature of about 400°C. A retort 8 in. diam. and 7 ft. long is shown by experience to have a capacity of about 5 tons of roasted zinc concentrate in 24 hours. Savings are claimed in handling the ore, in more efficient use of the heat, and in initial cost of plant. A small Hughes retort was given a trial test at Butte, Mon-

---

tana, in 1909-10, and a full commercial size retort is now installed at the demonstrating plant of the Hughes West Continuous Zinc Distillation Co. at Southampton, a suburb of St. Louis, Missouri.

Several methods have been proposed recently for smelting lead-zinc concentrate in the ordinary zinc furnace, producing lead-free spelter and a lead-bearing residue suitable for lead smelting. One of these is the Hopkins process, which employs essentially a charcoal or carbon filter between the retort and the condenser. It is found in practice at Swansea that this process, working on Broken Hill zinc middling, gave spelter 99.6% pure, as compared with 96.5% pure with ordinary condensers, and at the same time gave a much better recovery of the zinc. The increased recovery is due to the higher temperatures possible with this method. When the endeavor is also to raise the percentage of recovery, another charcoal or carbon filter is placed in the outer end of the condensers. In a 19 weeks test at Swansea, the Hopkins condensers and ordinary condensers working on opposite sides of the same furnace upon the same ore and in all other respects under the same conditions, the Hopkins condenser averaged more than 7% greater recovery.

A process for smelting zinc-lead slime and fine concentrate patented by Sulman and Picard, has been recently described. The scheme was devised to treat the fine lead-zinc slime resulting from the flotation processes at Broken Hill, New South Wales. This material could not be smelted profitably in the ordinary way because the lead destroyed the retorts and because the resulting spelter was too leady to be salable. In the experimental test the material was first carefully roasted in a hand-roaster, then mixed and made into briquettes composed of roasted ore, 70%; bituminous coal, 25.5%; and pitch, 4.5%. The briquettes were of such a size that 14 of them, 2 deep, just filled the retort. After distillation the briquettes came out of the retort quite porous, but intact, and well suited for direct lead smelting. There was no tendency for the retorts to 'slag up' in the bottom because the briquettes came away clear and whole each time. The recovery of zinc, based on the whole run, was 70%, but at times it exceeded 85%. The conclusion is that above 80% recovery would be maintained in commercial operation, which is excellent practice for that class of ore. As results of this process, an otherwise unavailable product was rendered profitable, the spelter commanded a premium for purity, there was 33⅓% increase in the capacity of the retorts, and there was a considerable saving of time and waste in cleaning and re-charging the retorts.

The problem of the complex lead-zinc ores has also been attacked from the electrochemical side. A 200-ton plant is under construction at Georgetown, Colorado, by the Western Metals Co., which will employ the Malm process. In this process the sulphides are subjected to partial dry chlorination in a tube-mill, the chloridizing is completed by agitation in a vat with hydrochloric acid, and the metals, except zinc, are, by an emulsion of zinc oxide, precipitated in a form suitable, after filtering through asbestos filter-presses, for treatment by lead smelters. The zinc chloride solution remaining is evaporated, fused, and electrolyzed, metallic zinc being thus recovered and the chlorine regenerated. The present plant is being constructed in the light of experience gained at the experimental plant previously in operation at Elkhorn, Montana.

Possible Source of Potash

In a recent Geological Survey report on potash, written by W. C. Phalen, the hope is expressed that every salt producer in the United States will in the future, when boring or otherwise exploring for salt, be on the lookout for possible occurrences of potash compounds. At present the Geological Survey has a deep-drilling party at work in the arid West, where vast deposits of salt are known to exist, in an endeavor to find possible sources of potash and nitrate of soda—two of the three essential elements of 'complete fertilizer,' a recognized necessity for successful agriculture.

Cement Industry of the United States

Ten years ago the production of portland cement for the first time passed the 10,000,000 bbl. mark, showing an increase of 2600%, over the production of ten years previously. Even this production was small compared with that of the present day. In 1910, according to the report on cement by Ernest F. Burchard, of the United States Geological Survey, the production of portland cement reached the enormous total of 76,549,951 bbl., with a value of $68,205,800. This is equivalent to 12,986,152 long tons, valued at $5.25 per ton. It is an increase over the output for 1909 of 11,558,520 bbl., or nearly 18%, and an increase in value of $15,347,446, or more than 29%. This increase alone is greater than the total output of portland cement in 1900. In addition to portland cement there was also produced last year 1,139,239 bbl. of natural cement and 95,951 bbl. of puzzolan cement, a total of 77,785,141 barrels.

The price of portland cement in 1910 was as low as 73c. in some places, the average for the United States being 89.1c. per barrel. In 1890 the average price was over $2 per barrel, and as late as 1903 it was $1.24 per barrel. The following table shows the healthy growth of the American portland cement industry and also the decrease in prices:

	Barrels.	Average price per barrel.
1880	42,000	$3.00
1890	335,500	2.09
1895	990,324	1.60
1900	8,482,020	1.09
1905	35,246,812	0.94
1909	64,991,431	0.81
1910	76,549,951	0.89

Titration of Potassium Cyanide in the Presence of Potassium Ferrocyanide

By W. D. Treadwell

Liebig's method for the direct titration of KCN with $AgNO_3$ is not applicable in the presence of $K_4Fe(CN)_6$. If, however, 0.1 gm. KI is first added to the solution, which should be about $^1/_{10}$ normal and slightly alkaline, accurate results are obtained. The addition of NH_4OH, as recommended by Denigès and Sharwood, is not necessary. The disturbing influence of $Na_2S_2O_3$ may be overcome by increasing the amount of KI to 1 gm. I found a satisfactory explanation of the above facts in a study of the silver ion in the various solutions. This was detected from measurements of the electromotive force of a concentration cell consisting of $^1/_{10}$ normal $AgNO_3$ and the solution to be tested. In the titration of pure KCN solutions with $AgNO_3$, it was found that upon the addition of the drop before the appearance of a turbidity, there was a sudden decrease in the electromotive force from 0.724 to 0.523 v., due to an increase in silver ions. Similarly the influence of excess NH_3, of $Na_2S_2O_3$, and $K_4Fe(CN)_6$ was found to be due to the formation of complex ions, and the lowering of silver ions below the concentration for precipitation of AgCN. Addition of KI caused in each case a turbidity due to the lesser solubility of AgI.—*Zeitschrift für anorganische Chemie.*

The uncertainties and the lure of mining in the Tintic district have been well illustrated by the recent return of the Gemini to the dividend list. This company, a close corporation of only 5000 shares, was forced to stop mining in the lower levels about four years ago on account of water. Some rather unpromising portions of the upper levels were developed, with the result that entirely new orebodies were opened, and from these the company has posted a dividend of $30,000. The previous total was of $2,000,000. The company is now figuring on pumping the lower levels and resuming mining operations there.

Treatment for Electric Shock

By H. H. Clark

*When a man has received an electric shock that leaves him senseless, two things should be done as soon as possible: (1) Remove the victim from contact with the electric wire. (2) Revive him or 'bring him to' by getting him to breathe. While removing the victim from the electric circuit, be careful not to get a shock yourself. If there is a switch at hand, cut off the current at once, but if there will be any delay in cutting off the current, remove the body from the circuit by means of a piece of dry wood, used either to roll or push the body aside or to lift from the body whatever is carrying current to it. Tools with dry wooden handles, such as picks or axes, may be safely used for this purpose. The body of the victim can be safely grasped if your hands are protected by several thicknesses of dry cloth, or if you stand upon a piece of dry wood. When you can do nothing else, you may be able to short-circuit the wire with which the victim is in contact, and thus blow the circuit breaker or fuses which protect that part of the electric system. A short circuit may be made by placing an auger, or drill, or a piece of pipe so that it will connect the two sides of the electric circuit. For example, in case the victim is in contact with a trolley wire, the auger, drill, or pipe should be thrown across the trolley wire and track rail, so as to be in contact with both. In doing this, be sure that auger, drill, or pipe leaves your hand before it touches the current-carrying part of the circuit, as otherwise you will get a shock yourself.

When the victim has been removed from contact with the current, turn him on his back, loosen his clothing from around his neck, chest, and abdomen, and place a small log, a rolled-up coat, or something of similar size and shape under his shoulders in such a way as to throw his head back and his chest up. The next thing to do is to draw out the victim's tongue, which can best be done by grasping it with a piece of dry cloth. This act clears the windpipe, and unless it is done, the victim cannot be made to breathe. If the assistant is alone, he will have to keep the tongue in this position by tying it with a handkerchief or a bandage passed over the tongue and under the jaw. The tongue must be held in this position while giving artificial respiration.

There are several methods of giving artificial respiration, but the one most commonly used is the Sylvester method. Kneel behind the head of the victim, grasp his forearms just below the elbows and draw them slowly backward until they extend as far as possible over his head, and hold them there for about one second. Then slowly bring the elbows forward and downward. Next press the elbows firmly against the chest and hold them there for about one second, so as to drive out the air from the lungs. Do not perform these movements too rapidly; swinging the arms up and down is a waste of time. To complete one series of movements should take about four seconds. A very good way to time yourself is to count, very slowly, 'one, two, three, four,' while making the movements. Count 'one' as the victim's arms are being extended, count 'two' while they are held above his head, count 'three' while his arms are being returned to his side, and count 'four' while exerting pressure on his chest.

Usually a victim of electric shock can be made to breathe within an hour, and the artificial respiration should be continued at least that long, even if the victim does not show any signs of being 'brought to.' If other persons are at hand, have them assist by relieving you at short intervals. Also have them keep the victim warm by covering him with coats or blankets, if any may be at hand. After the victim begins to breathe, the assistants should rub his limbs briskly and toward the heart, keeping their hands under the covering while doing so. This will help to restore the circulation of the blood, which has been for a time suspended.

While arrangements are being made for removing the injured man to his home or to a hospital, treat any injuries that the victim has received. Treat electric burns exactly as ordinary burns. Before the arrival of a doctor it is proper to cover the burnt place with several thicknesses of picric-acid gauze. This gauze is now being used in nearly all mines and hospital emergency rooms. In case no picric-acid gauze is at hand the burns may be covered with clean gauze, preferably taken from sterile packages, and covered with vaseline, carbolized vaseline, olive oil, linseed oil, or what is known as carron oil, which is a mixture of linseed oil and limewater. Cover these dressings with plenty of cotton and protect this in turn from the outside air with oiled paper or anything that will keep out the air while the victim is being taken home or to a hospital. Bandage all dressings lightly so as to cause as little pressure as possible upon the injuries.

---

*From Miners Circular 5, Bureau of Mines.

Mining Districts of Humboldt County, Nevada

The southern portion of Humboldt county, Nevada, is part of a metallogenetic province characterized chiefly by the prevalence of antimonial ores of silver with numerous and widely scattered deposits of stibnite and cinnabar. There are in addition some deposits of gold-silver, copper, and nickel-cobalt ores. Ore deposition probably began immediately after the intrusion of the Triassic and Jurassic sediments in late Mesozoic time by a magma of generally granodioritic composition, comparable with that which invaded the rocks of the Sierra Nevada at the same period, and continued into the Tertiary. The known Tertiary deposits are essentially gold-silver ores and copper ores, but it is possible that some of the other types are also Tertiary.—*F. L. Ransome, in Bulletin 414, of the U. S. Geol. Survey.*

Production of Tin in Bolivia

The official reports for the first quarter of 1911, according to the *Boletin Sociedad Nacional de Mineria*, give the tin exportation as 8819 tons of barrilla, or concentrate, containing 60 to 65% tin. This is 1269 tons less than the production for the corresponding period of 1910, the decrease being due to the destruction of the roads by floods. The production by districts was as follows:

	Tons.
Potosi	5344
Oruro	2938
La Paz	537
	8819

An old method of mine ventilation, the use of a heating stove to create a draught, is used extensively and effectively throughout Missouri. An ordinary wood or coal heater may be employed. It is stationed at the surface, near the mouth of the shaft. The pipe is run horizontally to a point directly above the shaft from which a vertical section can be extended to the bottom of the shaft. The lower portion need not be of metal piping, wooden boxing being effective, and in some instances even better than metal would be. The top extension of the pipe should be sufficiently high to create an excellent draught when a brisk fire is built. The suction effectively removes impure air from the mine workings. The plan is more satisfactory than the use of the canvas blow-pipe, another common method of ventilation found throughout the district.

Deep excavations in the Arbuckle mountain region of Oklahoma revealed an underground lake at a depth of 62 ft., the development being done on the land of Scott Braden, 6 miles southwest of Davis, Oklahoma. Pressure forced water, sand, gravel, and fossils high into the air. The development was being conducted in search of zinc ore, several fair finds having been made in the immediate vicinity.

Lead and Zinc Mining

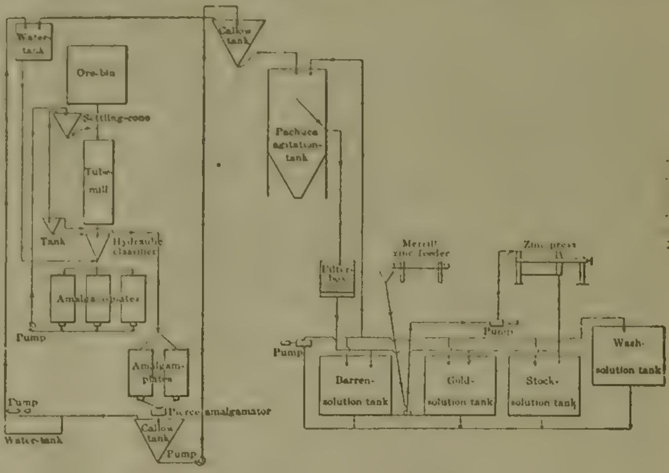
By B. S. Butler and J. P. Dunlop

*Mining and milling practice in the Joplin region is so well known through the numerous articles that have already appeared that but few words are necessary here. The type of mill erected in the southwest Missouri district is carefully chosen to fit the needs of the particular kind of orebody to be exploited, and, being based on the evolutionary experience of nearly forty years, is in general wisely selected. In early days of zinc mining in the district, when only the richest runs and pockets of the 'disseminated' deposits could be profitably worked and the life of the individual mine was necessarily short, a simple type of concentrating plant came into use. It was equipped with a rougher-jig and a cleaner jig, and had a capacity of 80 to 100 tons of crude ore per 10 hr. shift. When a deposit was worked out, the mill could be easily and cheaply moved to another deposit. When the increased price of concentrate made it possible to mine lower-grade ore and the life of the deposits was thereby lengthened, somewhat larger and more complete milling plants came into vogue. Sand-jigs and concentrating tables were added to the equipment, and the capacity was raised to 200 tons or more per shift. Such mills, developed by the necessities of local conditions, came to be characterized throughout the lead and zinc regions of the Central States as the 'Joplin type.'

The lead and zinc ores of the Central States, when marketed locally, are sold on a plan which differs somewhat from the methods in vogue in Western and other States where more complex ores prevail. The producer is paid by the ton of concentrate, all ore being sold in that form. The price is arranged on a sliding scale, the foundation of which is the price paid for ore of a certain standard, namely, the 'basis.' In each of the ores a 'basis' is arbitrarily taken which represents as nearly as may be the average metallic content of clean concentrate. In sphalerite or zincblende concentrate the basis is 60% (theoretical composition, 67%) of metallic zinc, by wet assay or analysis; in the oxidized zinc ores (the carbonate and the silicate), the basis is 40% (theoretical, 52 and 54%) metallic zinc; and in galena concentrate the basis is 80% (theoretical, 87%) metallic lead. The buyer will offer so much for 60% zinc ore which becomes the 'base price.' If the assay shows the concentrate to vary from the basis, $1 is added to the base price for each per cent of zinc above 60, and $1 subtracted for each per cent less than 60. Deduction is made for moisture, all concentrate being sold on dry, or net, weight. Penalties are exacted for the presence of undesirable elements, as iron, bitumen, barite, and fluorspar; $1 is deducted for each per cent of iron above 1%. The first ore sold from the new Miami district was penalized 2%, that is, $2 was arbitrarily deducted for the bitumen clinging to the concentrate. The blende concentrate from Miami averages about 50% zinc, and is penalized $10 per ton for falling 10% below the 'basis', as well as an additional penalty for the iron content. In practice, however, it has been found that these penalties are heavier than necessary, and the ore-buyers offset the excess by increasing the basis offer over the base price obtaining in the other parts of the Joplin region where the concentrate averages nearer 60%. Fluorspar occurs in the zinc concentrate of western Kentucky and southern Illinois, but neither fluorite nor barite is found in quantity in the ores in the Joplin or the upper Mississippi Valley districts. The practice of buying zincblende concentrate on an assay basis became general in 1899, though it began in a small way a few years earlier. Formerly the ore was bought on 'flat bid', that is to say, the buyer made a visual inspection and mentally estimated the metallic content very closely. Galena concentrate is generally bought on flat bid, though buying on assay is increasing. Ore which is sold in lump, such as hand picked galena, lead carbonate, and carbonate and silicate of zinc, is very generally sold on flat bid.

An Experimental Cyanide Plant

In designing a cyanide plant at the Alaska Treadwell mines, it was judged wisest to make exhaustive experiments before undertaking construction, as the capital thus expended would be repaid in the more effective working of the mill as finally constructed, and by the saving in the cost of the alterations usually necessary in a new plant. Preliminary tests were made, under the direction of W. P. Lass, in glass jars, and followed by tests upon 50-lb. lots by grinding in a small clean-up barrel filled with iron balls, the pulp being agitated in a 14 in. by 4-ft. Pachuca tank. Next a 4 by 12-ft. Abbé tube-mill was installed, the pulp passing over amalgamated plates to a Dorr classifier and Callow cones were used for dewatering the sand before cyaniding in a 10 by 22-ft. Pachuca tank, the classified solution going to a Merrill precipitation press. With this equipment 15-ton lots could be treated. The gold content was removed from the pulp by successive washes and treatment. The accompanying flow-sheet shows diagrammatically the method used for these experiments, with the exception that the filter-box shown was later superseded by a Kelly filter-press (type 1 B) of 50 tons daily capacity, which did away with the numerous washes and decantations previously required. With this equipment a complete series of tests was carried out, with the result that when the 100-ton plant was constructed it was operated from the start without any hitch.



FLOW-SHEET OF EXPERIMENTAL CYANIDE PLANT.

American manufacturers deserve a great deal of credit for their efforts in producing suitable permissible explosives to meet the economic conditions in the coal mines of this country. Many of the permitted explosives used in European countries would not be suitable for use in the bituminous coal mines of this country for the reason that they are much stronger and quicker in action. If such explosives were used in mines of this country according to our American practice, depending to a great measure on the execution of the explosive, they would fail in their purpose. For this reason the American manufacturers have found it necessary to reduce the strength and quickness of explosives for coal-mining purposes by adding inert materials or restraining substances. With explosives of this kind the average miner, after a short time, obtains successful and satisfactory results.

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Surface Indications of Ore-Shoots in Depth

The Editor:

Sir—After reading Mr. Cutler's article on pitch of ore-shoots in your issue of October 28, I am more than ever in love with the old rule: when you are in ore any change (of formation) is a bad sign, and when looking for ore any change is a good sign. Now in Mr. Cutler's second paragraph reading "When following an ore-shoot in a vein, a change in the vein or a disturbance is unfavorable * * *"; if we read "when looking for an ore-shoot in a vein * * *" then, by all means, what is needed is a gulch. Though I rather think that the prime cause of most gulches is that you cannot have two hills without one. In other words, if you look for the cause of the ridges, the gulches are a natural sequence.

I quote you from 'The Practical Handbook for Miners,' J. A. Miller, 1897, p. 95: "When a river forks at its head into two or more branches, it is strange to say, the source of the gold will nearly always be found in the right-hand branch geographically speaking * * * you are supposed to stand at the head of the river or stream, looking toward its mouth or outlet." Now this was evidently a rule in those days, whether it is now or not. Again, p. 103: "Observation shows that most mineralized mountain chains extend into a northeast and southwest direction—that is, roughly speaking—and that most metalliferous lodes run at right angles to the main axis of elevation of the ranges; it follows that lodes must have a more or less east and west strike."

Now, why should not ore-shoots have their little habits also? If it were possible to compare data from several camps, it would help settle the point whether ore-shoots in general favor a certain direction in their pitch.

It was not so long ago that a faulted vein meant digging in every direction; now there are rules for this, thanks to careful study and comparison. Of course, I don't say that Mr. Miller is infallible, as on p. 73 he tells us that "the almost microscopic infusoria * * * lay down beds of limestone and sandstone hundreds of feet in thickness." But this was before they found gold in the grindstone. Also, on p. 109, he says "pyrites or mica, which is the same thing"—which latter is rather a gem.

In these matters it is well to remember that fifteen years hence many of our present ideas will be laughed at. I can remember twenty years ago that an 'expert' would hardly look at a property in limestone. Granite and slate contacts were the fashion then. How long has it been since the tellurides were generally recognized—and are they really understood yet? Twenty-five years ago the Cornishmen used wolfram for ballast and wall building, and yesterday some zinc was overlooked. Tomorrow there may be a rule to find an ore-shoot in depth without following the ore *antigua* style. Before bidding good-bye to Mr. Miller, I quote a few sentences from his 'Mining Investor's Handbook', p. 192:

"The mining prospectus is got up for the purpose of selling the shares of its respective company and addresses itself especially to the unwary and gullible public. Nobody is responsible for the statements the prospectus contains. Nominally the directors are the responsible parties, but as it happens as often as not, the prospectus comes into existence long before the board of directors, and in not a few cases they themselves have been caught and deceived by their own prospectus. What is wanted is to make the prospectus innocuous. The prospectus should emanate from a practical mining engineer of good standing, who should be held responsible for every statement made in it. The prospectus should be signed by the compiler and also by a goldfields warden or magistrate residing in the neighbourhood of the mine, testifying to the respectability of the compiler and also as a guarantee of good faith that the ground proposed to be mined does really exist, and is the property of the company." Thus in 1897 and 1911, "which is the same thing."

SONORA.

Nacozari, November 3.

Mining Opportunities in the Orient

The Editor:

Sir—Having noticed frequent references to Oriental affairs in the *Mining and Scientific Press* recently, I would like to ask your opinion of the opportunities for mining now existing in Japan, Korea, and China, and I think many others among your readers would be similarly interested. Is the general impression that abandoned native mines in southeastern China offer a profitable field for exploitation by foreign companies a correct one? What effect will the revolution in China have upon mining development?

ENGINEER.

Salt Lake City, November 10.

[The mining laws of Japan, like those of the United States, are not framed to encourage mining exploitation by aliens, and there is little attraction for foreign mining investors. Korea, which now belongs to Japan, is governed by regulations which offer liberal terms to foreigners and foreign companies, though regarded as onerous by some who were accustomed to the provisions imposed by the former Korean régimé. The country offers a promising field for mining, as native workings are widespread. Frequent references to the companies now operating in Korea appear in our columns. China, generally speaking, offers little field for foreign exploitation, as the experience of the Government with foreign concessions has been so unsatisfactory that it is safe to say that no more will be granted, unless under extreme diplomatic pressure. A good deal of native capital is being invested in the development of coal mines, but we regard the coal supply at present available ample for present needs, though the demand is likely to grow rapidly. The demand for capital for industrial development is so great that mining, other than coal, is somewhat neglected by native investors. The general impression as to the mineral wealth of southwestern China is well founded, to a certain extent at least. The Burma Mines, Ltd., is successfully operating an abandoned native lead mine and slag-dump in the Shan States, a short distance west of the frontier. The Syndicat du Yunnan has a 60-year concession on 40,000 square miles in Yunnan, but though it has been in existence for ten years, little has been accomplished on account of local difficulties and the opposition of the people and officials of the province. It is to be feared that the revolution, if it should be successful, will hamper rather than encourage mining development. The underlying cause of the outbreak is popular opposition to the wholesale incurring of foreign loans for the development of railways and industry, and in any case the financial situation in China will be bad for some time. There will always be opportunities, of course, for individuals to enter the employ of the companies now in operation and to engage in work in various other ways, but in all cases the engineer should see that he is provided with a properly executed contract and funds for traveling expenses before venturing so far from headquarters. Generally speaking, living conditions are excellent in the Orient, and the climate is nowhere unhealthful when reasonable precautions are observed.—EDITOR.]

THE MESABI IRON RANGE in Minnesota produced in 1910, according to the United States Geological Survey, 53¾% of the entire iron ore production of the United States. The Lake Superior district, including Minnesota, Michigan, and Wisconsin, produced 81½% of our total iron ore production. Figures from other countries are not yet available for 1910, but this is probably a greater production than the entire year's output for any foreign country.

Concentrates

Most of these are in reply to questions received by mail Our readers are invited to ask questions and give information dealing with the practice of mining milling and smelting

TIN EXPORTS from Perak for August are given as 7642 piculs of block tin and 31,439 piculs of ore. A picul is approximately equivalent to 133 lb., and equals 100 kin.

ON melting copper, it is important that none of the copper project above the charcoal. Any copper not covered by charcoal will be oxidized or 'burnt,' and the casting will be weak and full of holes.

IN MINING and milling low-grade orebodies power becomes a large factor in the total cost. A former manager of a custom mill for complex lead, zinc, and iron ores at Leadville reported that power amounted to 25% of the total cost of operation of his mill.

MILLSITES having no connection or association with a lode claim, cannot be patented unless each millsite has a mill or other reduction works upon it. Plants of another nature, even though of service to a mill or mine, or other uses of the claim, will not satisfy the law.

ALLUVIAL deposits are sometimes worked upon a royalty basis; the amount of royalty paid depending upon the working conditions and cost and the richness of ground. In one case 10% of the gross proceeds was paid, but 20 to 25% of the net proceeds is the more usual arrangement.

HOT brass cylinder heads and jackets may be cleaned by using the following recipe. Sift coal ashes fine and mix with kerosene oil to a thick paste; add as much air-slaked lime as can be conveniently mixed with it. Apply this polish to the bright parts, rubbing hard; wipe off and polish with dry slaked lime.

IN melting brass or similar metal, too strong heat is detrimental. Portions of the metal exposed will be melted and oxidized before the rest is melted. The best practice is to have the metal melt as uniformly as possible, so that all portions become liquid at about the same time. This avoids overheating any portion.

MALDONITE is a well defined compound of gold and bismuth, and was first discovered in the quartz of the Nuggetty reef, Maldon, Victoria. It has a pinkish silver-white color when freshly broken, but tarnishes to a dull copper, and finally to black. Before the blowpipe it yields a bead of gold and the usual bismuth coat.

MAKING forgings and welds is aided by directing a jet of compressed air against the heated ends of the work. The air-blast will cause a display of fireworks and will considerably raise the temperature of the metal just prior to making the forging or weld. By this means it is possible to revive the heat in a piece that has become cooled. The air-jet will also blow off all dirt and scale. It will burn the metal faster, and it will increase the heat.

WATER may be appropriated in California by diverting it for some useful purpose, the appropriation being good from the time of diversion. A notice is placed at the point where the water is diverted, stating the amount of water taken, the purpose and place of use, and the means of diversion. This is duly recorded and the work of diversion must be begun within 60 days of the posting of the notice, and carried on with all due diligence to completion. The failure to make use of the water for a beneficial purpose for five years is held to constitute a forfeiture of the right.

FOR a water-supply system the quality of the water available determines its usefulness quite as much as the quantity. Some waters contain ingredients that make it impossible to use them for irrigation unless certain precautions are taken in applying them to the land and in draining them off. Certain ingredients in water make it unavailable or destructive if used in boilers, and the quality of water used in a manufacturing plant may largely determine the quality of the product of manufacture.

THE following substances are held to be locatable under the placer laws when found in placer form; when occurring as veins or lodes, even if primarily formed as placers, it appears that they should be located as lodes. The last three are the subjects of special placer acts.

Alum
Amber
Asphaltum
Borax
Building gravel (uncertain)
Building stone
Gas
Gold-bearing gravel
Guano
Gypsum
Iron beds
Kaolin or fire clay
Limestone
Marble
Mica
Phosphate (uncertain)
Salt beds and springs
Slate
Soda
Sulphur
Tailing and slag
Petroleum

DIATOMACEOUS EARTH is chiefly used for cleaning and polishing, either in the form of powder, or mixed with soap. It is an effective non-conductor of heat and has been used alone, or with various compounds, for coverings for boilers, steam pipes, and safes and in fireproof cements. Its great absorbent qualities fit it admirably for use in water filters and for dynamite. For the latter use it is mixed with wood pulp. It is used largely by paint manufacturers as a wood filler. Boiled with shellac it is made into records for talking machines. In Germany it has been used for the absorption of liquid manures so that they could be utilized as fertilizers, as a source of silica in making water glass, in the manufacture of cement, tile glazing, artificial stone, ultramarine and other pigments of aniline and alizarine colors, paper filling, sealing wax, fireworks, hard-rubber objects, matches, and papier-mâché, for solidifying bromine, and for many other purposes. The value runs from $6 to $9 per ton.

NITRATES can be tested qualitatively in the field, but there is no process known by which a prospector can make a test that is very reliable. There are, however, two methods which are pretty good indicators. One depends upon the fact that caustic soda or potash (NaOH or KOH) will act upon aluminum to produce hydrogen, and nascent hydrogen will act upon nitrates in such a way as to produce ammonia. The process, then, is for the prospector to furnish himself with a number of small aluminum cups, sticks of sodium or potassium hydroxide, and a small measuring cup, such as a cartridge filler, which would be the only outfit he would have to carry. He would then take specimens of the soil or mineral which he wished to examine, measure it in his cartridge filler, and put it in the aluminum cup with a certain amount of water, always the same, and then add his hydroxide. By the strength of the ammonia odor evolved he could judge about how much nitrate was present. In this or in other processes used, careful tests should be made before going into the field, in order to become acquainted with the reaction and with the amount of ammonia produced from given amounts of material. The best way to do this would probably be to take clean sand and add to it varying known percentages of saltpetre. After making such tests a number of times, a prospector would be able to judge roughly of the percentage of nitrates contained in samples of the same size in the field. This experiment is ordinarily made by using a glass vessel and strips of aluminum, but by using aluminum cups which would nest there would be less bulk to carry, and this would obviate the carrying of glass, always an undesirable object in outfits which must be packed from place to place.

Special Correspondence

LONDON

Differing Opinions as to Future of the Tanganyika Concessions.—Financial Crisis Impending in the Company.—Secrecy Hides Principals in Recent Tin 'Corner.'—Orsk Goldfields.

Interest is being shown in the copper enterprise belonging to the Tanganyika Concessions, situated in Katanga in the southern part of the Congo State and just over the border from Rhodesia. The chief mine is the Star of the Congo. For eight years or more this copper deposit has been before the British and Belgian publics, for the ownership and control is about equally distributed in the two countries. In a general way it may be said that the company arrangements in the two countries are such that Belgians control the financial side, and Robert Williams, the English head, is responsible for the administration and the mining and metallurgical operations. Various reports have been issued as to the extent and metallurgical value of the ore, which is almost entirely carbonate. Mr. Williams, who is neither a mining engineer nor a metallurgist, says there is enough ore to produce 100,000 tons or even 200,000 tons of copper per year for an unlimited number of years. Unfortunately, the opinions and views of experienced men capable of judging have never been sought, so in well informed circles there is an air of polite incredulity. One of the first requisites necessary for the exploitation of the deposits was railway communication. A year ago the Rhodesian Railway system was completed to Elizabethville over the Congo border and not far from the 'Star', and by this means access was given from Cape Town to Beira. A railway is also planned and is partly completed from Katanga to Lobito bay on the west coast of Africa. With the best of communications, however, the cost of sending coke from Europe is tremendous. At present no coking is done on Natal, Rand, or Wankies coal, and, indeed, the deposits nearest to the mine are not suitable for the manufacture of metallurgical coke. The smelter started operations this summer, and many rumors have been in circulation as to the difficulties experienced. It is beginning to be realized that a young and inexperienced metallurgist like Allan Gibb is the wrong man for the place. Mr. Williams, however, still sticks to his guns in a hopeless and despairing sort of way, and issues lamely optimistic circulars, giving all sorts of excuses for the absence of information, such as "badly mutilated cablegrams." Such information as is vouchsafed, unintentionally reveals the fact that the metallurgist is at his wits' end to get a good smelting mixture. The congeries of companies forming the Tanganyika group is approaching a serious financial crisis, for the available cash resources are nearly exhausted and the debenture interest is a long way in arrears. The quotation of the ordinary £1 shares is falling steadily, and is now £2 as compared with £7 eighteen months ago. I should not be surprised if the shareholders received an ugly blow even before this letter is in print; but in any case the crisis cannot be postponed later than Christmas.

During the last six or nine months there has been an artificially inflated price for tin, due entirely to the machinations of certain merchants who have been able to corner the visible supplies of such metal as is sold on the London Metal Exchange. I am sorry to say that I am not able to give your readers the names of these speculators, for the simple reason that members of the Metal Exchange do not give away the secrets of their trade to journalists or to the public. In this way they resemble the tin smelters, who are equally secretive. It is really good of the trade not to 'split' on each other, but I suppose there is such a thing as honor in other circles than the proverbial one. It is not generally known outside the metal trade that the only brands of tin sold on the Metal Exchange are those of high quality, such as are necessary in the manufacture of tin-plates. This tin comes from the Federated Malay States and the islands of Banca and Billiton in the Dutch East Indies, these two sources being classed as 'Straits Tin,' and from Queensland and Tasmania. The ores from which these brands of tin are produced are mostly concentrates from gravel, and are notably free from other metals. The assay of Banca, Billion, Penang, and Singapore tin is 99.9% or more; Mt. Bischoff tin from Tasmania assays 99.8%, and Queensland brands run 99.6 to over 99.9%. These are the only brands sold on the London Metal Exchange, and the product of the Cornish, Liverpool, and German smelters is disposed of in other ways, though as a rule through firms of brokers who are members of the Exchange. Tin produced by Cornwall, Liverpool, and German smelters comes from Cornish and Bolivian ores, chiefly. These ores are not gravels, but are found in veins, and usually are associated with many other minerals and metals such as lead, antimony, arsenopyrite, and wolfram. The metal runs 98¾ to 99.9%. In addition many other brands are on the market, especially in Bolivia and China, that run as low as 95% tin. The brands that are not sold on the Metal Exchange are used chiefly in the manufacture of brass and other alloys, a fact which explains the establishment at Liverpool of branches of the Williams-Harvey and Penpoll smelters, a course adopted because the brass market was in close proximity. Owing to the recent 'squeeze' in tin, the majority of the members of the London Metal Exchange have been in favor of widening the source of supply for their official transactions, so a 'Standard' contract has just been adopted that allows high-class refined metal above 99¾% to be dealt in on the Exchange at the official price, in addition to Straits and Australian tin. This rule will allow much of the English and German tin to come within the scope of the dealings of the Exchange, and the increased supply will tend to prevent 'corners'. In addition, any tin assaying from 99 to 99¾% may be dealt in on the Exchange at £7 per ton lower than the Standard, thus providing further resources in case of need, though, as a rule, the penalty of £7 will be too great to induce transactions through the official medium. There is a great deal of unnecessary mystery in connection with the new scheme, and many people think that the smelters, and the mines producing low-grade ore, will suffer. This is not the case, apparently, and the above statement ought to clear the air of many misconceptions.

The Kolchan dredge of the Orsk Goldfields started operations on October 21, and a three weeks' run is expected for this season. It is reported that the stacker-scow has cleaned up $122,000.

MEXICO

A. S. & R. Smelter at Chihuahua Resumes Operation.—Development at the Mololoa.—Semiannual Report of San Rafael y Anexas.—Exploration Company Ventures.—Proposed Line from Guadalajara to Mexico City.

The Chihuahua smelter of the American Smelting & Refining Co., closed several months ago as a result of labor trouble following the revolution, is again in operation and soon will be running at full capacity. The company has decided to add two furnaces at this plant, giving it a total capacity of 900 to 1000 tons per day. Work on the smelter additions is in progress. Operations likewise have been resumed at the Terrazas smelter of the Rio Tinto Copper Co., another Chihuahua plant that was closed several months ago as a result of disturbed conditions. Several hundred tons will be handled daily. In the State of Chihuahua the mining industry is rapidly regaining the ground lost during the revolution, and it is believed the coming year will witness great activity. It is said that the new State government in Chihuahua plans measures of benefit to the mining interests. Recently the Mexico Northwestern railway commenced operating trains on the 22-kilometre branch that gives the Cusihuiriachic silver district in Chihuahua transportation facilities, and that road has let a contract for the building of another branch, 47 kilometres long, from Pearson to Colonia Pacheco. This latter branch will benefit the Dos Cabezas and other important mines. Orders have been placed for additional machinery for the two big mills of the Parral district of Chihuahua, the Palmilla and Veta Colorada, and these plants will handle increased tonnages during the coming year.

The old Mololoa mine in the Hostotipaquillo district of the State of Jalisco, one of the famous antiguas of western Mexico, is again in bonanza ore, and present shipments of high-grade ore are netting the Mololoa Mining Co. from ₱2500 to ₱3000 daily. Power for increased development is to be supplied by the building of a branch transmission line from the El Favor station of the Chapala Hydro-Electric Co. A reduction plant to treat the milling ore existing in the old workings, and that being opened by new development, will be built during the coming year. Much rich ore is being found in stoping in the big El Favor mine in the Hostotipaquillo district. A recent shipment of 26 tons netted the company ₱11,400, or ₱440 per ton. The mill at El Favor is now operating steadily. The aerial tramway that will carry the ores of the Espada Mines Co. to the Virginia & Mexico mill, in the Hostotipaquillo district, will be completed about the middle of December. The reduction plant is under lease to the Espada company. The Chapala Hydro-Electric Co., which has experienced much trouble in operating its Hostotipaquillo and Etzatlan transmission lines during the past rainy season, will change its insulating system during the present dry season. The company is completing a new 12,000-hp. hydro-electric plant, planned to supply mining districts principally. The Almoloya M. Co., of Mexico City, which has been operating in the Ameca district of Jalisco for a few years, has bought the old Cerrito copper mine in that district for ₱50,000. The Magistral-Ameca Copper Co., of Los Angeles, which abandoned operations at the Magistral mines in the Ameca district some months ago on account of disturbed financial conditions, has resumed work on a double-compartment shaft that is expected to prove the property at depth.

A report covering the operations of the San Rafael y Anexas Mining Co., one of the most successful companies of the Pachuca district of Hidalgo, during the first six months of this year shows a gross production of ₱1,649,556, and a profit of ₱546,114. A total of 71,587 tons was mined, the mining cost amounting to ₱6.56, and the milling cost to ₱3.94 per ton. The average yield was 653 grams silver and 3.43 grams gold. The company disbursed in dividends in the six months ₱434,400. The company formed last year by well known Pachuca mining men to build a custom milling plant in the El Chico district of Hidalgo, and which stopped work because of the revolution, is getting ready to resume operations. The company has contracts with El Chico mines for sufficient ores to keep the proposed 100-ton mill operating at capacity. The Pachuca Light, Power & Railroad Co. is completing its Pachuca-Real del Monte electric line, and will have it in operation early in the coming year.

The Exploration Company of England & Mexico has surrendered a three-year option on the Cometa property, adjoining the mines of the El Oro Mining & Railway Co., in the El Oro district of the State of Mexico, which was arranged early in 1910. It was believed that the Cometa contained important extensions of El Oro veins, but evidently developments since the option was taken have not borne out this belief. El Oro Mining & Railway Co. is retreating tailing that accumulated in the early days of the company's milling, the supplies amounting to 450,000 tons. It is estimated that a profit of $700,000 will result. The annual report of El Oro Mining & Railway Co., covering the year ended June 30 last, shows a gross production of $2,389,349 from 360,294 tons of ore, and a profit of $984,333. The profit from the railroad was $103,120, making a total profit of $1,087,453. Working costs were reduced from $4.93 to $3.90 per ton. The dividends paid amounted to 15%. The company is controlled by the Exploration Co., Ltd., of London, of which the Exploration Co. of England & Mexico is a subsidiary.

Southern Pacific engineers from San Francisco have started from Guadalajara, the Jalisco capital, to survey a line from that city to Mexico City. A concession for this line was granted by the Diaz government. The West Coast extension of the Southern Pacific will be completed into Tepic, the capital of the territory of that name, in December. In closing the gap between Tepic and Guadalajara the Southern Pacific will have to cross the *barrancas* of the Sierra Madre, and it is estimated that this crossing will cost from ₱7,000,000 to ₱10,000,000.

JOHANNESBURG, TRANSVAAL

Welgedacht Exploration Co. Closes Down. Government to Reduce Tax on Diamond Mines. Schuller Mine in Difficulties.

Since my last letter was written drawing attention to the wholly inadequate steps taken at Welgedacht to sink through the dolomite formation, and the discredit likely to be caused thereby to that portion of the Far East Rand goldfield, the truth of my remarks has been exemplified in a striking manner during last week. The directors have discovered that the plant and equipment is such that, with safety, even such a small quantity of water as 60,000 gal. per hour cannot be dealt with, and have decided to close down. A new board of directors has, however, been appointed, but the circumstances surrounding the company are such that it is doubtful whether—at least for some time to come—shaft-sinking operations will be again resumed. According to the bore-hole results, this shaft was going down upon what appeared to be a most promising area of the Far East Rand Goldfield. This failure of the Welgedacht Exploration Co. to handle its property in a workmanlike manner, is sure to throw discredit upon a goldfield whose value and possibilities have just been materially benefited by the excellent returns secured at Brakpan.

PREMIER DIAMOND MINE.

Diamond mining in the Pretoria district still continues under a cloud, and were it not for the fact that the Premier mine is worked on an exceptionally large scale, profits under the circumstances would be out of the question. The 60% profit paid to the Government is an incubus the industry ought not to be expected to carry, and it is reported that some alteration in this respect is contemplated by the Government. The Premier mine is the only diamond mine of importance in the Transvaal, and when it was first opened the prospects were so dazzling that even a 60% share of the profits did not seem too much to pay to the Government. Since then, however, the yield has fallen with depth to such an extent that only by working on an unprecedented scale has the company been able to pay the tax, and any inconvenience caused by such a heavy tax on the industry has been thrown upon the shoulders of the shareholders. Why a diamond mine should be called upon to pay six times as much as a gold mine it is impossible to say, and an early readjustment of the burden will be welcomed by all concerned.

Some attention has lately been attracted by attempts to open up the old Schuller diamond property in the Pretoria district, but so far the work done has been, as regards capital, of such a hand-to-mouth character that it is extremely doubtful whether the efforts of the prospecting syndicate can be expected to meet with success. The diamond pipes are so small and yield such a poor grade stone that only by working on an extensive scale will operations be conducted at a profit, while it is doubtful whether the syndicate will ever be able to command the necessary capital to enable mining operations to be conducted on a sufficiently large scale to be profitable.

Despite the many disappointments and losses incurred by the working of the Montrose diamond mine since the present company resumed operations, despite the fact that diamond experts are agreed that the so-called mines are of a worthless character, additional capital is being expended on the property. Month in and month out, operations are being conducted at a loss, and were it not that the mine is controlled from London, where a market exists for the shares, most probably the mine would have been closed down months ago.

TORONTO, CANADA

Lake Navigation Closed.—Many Power-Plants Proposed.—Prospecting Results Encouraging.—Development in the District.

Lake navigation in the Porcupine district closed about November 1, owing to the formation of heavy ice around the shores. At the same time land transportation became difficult owing to the partial freezing over of the roads, the frost not being sufficiently severe to form good winter traveling. The roads, abounding in deep mud-holes, were made impassable for heavy traffic and a number of horses were killed in attempting to overcome the difficulties of moving freight. Building has practically come to an end for the season, a great deal of work having been accomplished during the last few weeks. At the new town of Timmins sixty buildings have gone up in two months. The district will be abundantly supplied with electric power if all the proposed enterprises are carried out. The Porcupine Power Co., with a plant at Sandy falls on the Mattagami river, which has a number of contracts with mines, will not have a monopoly of the field. S. W. Wallberg has 400 men at work constructing a dam at Waiwaietan falls on the Mattagami to supply power by a transmission line to South Porcupine, twenty miles distant. It is hoped to have the line finished by the end of the year. Surveys have also been made and a company organized by Daniel Clark of Cobalt with the object of constructing a third power-plant at High falls on the Frederickhouse river. At the Dome good progress is being made with the power-house and stamp-mill, and it is hoped to have the mill in running order March 1. Recent operations have consisted principally of surface prospecting and diamond-drilling, proving the existence of large quantities of good milling ore. The deepest hole sunk reached a depth of 750 ft., showing the persistence of the surface formation. For 1000 ft. across the property surface prospecting has discovered outcroppings of high-grade ore. The Golden Stairway vein continued down to 200 ft. The main shaft is now down to 180 ft., and it will be continued to 400 ft. before considerable exploration work will be undertaken. The management of the Rea mine has been undertaken by Bert Pourrier, who will also retain his position as manager of the Vipond. The vein has been reached by cross-cutting on the 300-ft. level, 35 ft. from the shaft, where it is found to have widened considerably and to contain sulphide, though but little visible gold. At the 200-ft. level driving shows that the vein runs between 2 and 6 ft. wide, with good free gold for about 300 ft., splitting up and disappearing at both ends of the drift. New finds of outcroppings have been made on the surface, and cross-cuts are being run to tap them underground. The main shaft of the Dome Extension is now down 170 ft., and at 200 ft. a cross-cut will be run to cut the Anchor vein. F. Augustus Heinze visited the West Dome about the end of October and announced that a mill would be erected in the spring. The main shaft is being cross-cut at 125 ft. to catch several veins which show on the surface. The Cartz vein on the adjoining property recently acquired by the West Dome is being worked. A shaft has been put down 20 ft., the ore showing free gold. At the Vipond the main shaft is down 200 ft., and cross-cutting has been begun in two directions. About 650 ft. of underground development has been accomplished at the 100-ft. level. The new 100-ton mill is expected to be ready for operation in February. The principal work now in progress at the Dobie is the sinking of No. 2 shaft, now down 75 ft., a short distance lower to find a large orebody discovered by diamond-drilling. At the Jupiter the vein of No. 1 shaft has been driven on at the 100-ft. level for 84 ft. and found to contain gold. A cross-cut from the shaft on No. 3 vein at the 100-ft. level shows the vein to be 21 ft. wide, yielding good ore. Work on the Porcupine United, which was suspended at the time of the fire, has been resumed, under the management of T. S. Jenkins. The Eldorado has found free gold in the shaft, now down 25 ft. A controlling interest in the North Dome has been secured by the Temiskaming Mining Co. of Cobalt. The Wright-Hargraves claims, four in number, situated southwest of Kirkland lake in the Swastika district, have been purchased by W. Young, of Haileybury, and associates for about $20,000. At the Swastika mine two cages in the new 3-compartment shaft are in operation, and good milling ore is being extracted from the vein, which is 10 ft. wide on the 200-ft. level.

The Amalgamated Asbestos Co., operating a number of asbestos properties in Quebec, is in difficulty and likely to make default in the payment of interest on its $8,000,000 bond issue due December 1, amounting to $200,000. The earnings of the company for the past six months do not equal this sum, notwithstanding every effort to cut down operating expenses. The company will probably pass to the possession of the bondholders, and its reorganization is looked for.

The Laurentian gold mine, in the Manitou Lake district of northwestern Ontario, which has experienced many vicissitudes in the course of the last few years, has been purchased by E. E. Hedges, of Boston, who purposes to continue development work through the winter and is arranging for additional machinery.

NEW YORK

Decreased Copper Surplus Surprises Public.—Foreign Manufacturers Experience Boom From Low-Price Copper.—Ray Con. Issues First Report.—General Market Notes.

The copper producers sprung something of a surprise upon the general public when the statement for October was put out. It has been generally and confidently predicted that there would be a material increase in the surplus, estimates running all the way from 6,000,000 to 15,000,000 lb. When it appeared therefore that the October demand had not only taken all of the month's output, but some 5,897,214 lb. in addition, it was felt that the copper situation was and is making some real progress toward the long wished for higher price levels. Output for the month was 118,255,442 lb., an increase of 2,666,492 as compared with September. Domestic consumption was 64,068,307 lb., an increase of 6,756,723 lb. over the September figures. Nevertheless it was the export demand that saved the day, consumers abroad taking 60,084,349, as against 50,824,011 lb. for September. It is one of the hardships of the present copper situation that the metal output is for the benefit of the consumer abroad. Neither the manufacturer at home nor the consumer of the manufactured product is getting any just proportion of the benefit derived from the flood of red metal that is turned out by the smelters. If such were the case the nation as a whole would not suffer so greatly. As matters now stand, the German manufacturer has the laugh on all the rest of the world. He is going at top speed with raw material cheaper than ever before, and not only cheap but plentiful, and with no reason to apprehend any immediate change in conditions. On the other hand, when the American manufacturer does come into the market he will be bidding against himself. For months he has been importuned to act as the savior of the metal market. In a way, the domestic buyer will evidently have to bear a double burden. There seems to be but one element that is not altogether for the better in the metal market. It is not known just how much or what proportion of the so-called export deliveries goes directly into consumption. The industrial expansion in Germany has been tremendous, and a reaction is to be expected and should be anticipated, rather than any further increase in demand. Germany has been for some months the chief foreign user, and it is hardly to be expected that the present demand can be kept up indefinitely. The copper surplus of 134,997,642, as compared with the record mark of 165,995,932 lb., does not apparently show such a decrease in accumulation as would warrant any great enthusiasm; however, the present accumulated supply of the world is 273,884,362 lb., which, compared with 401,249,967 lb. surplus as of July 1910, shows that in spite of the tremendous amount of copper which has been produced, consumption has made material inroads upon the world's visible supply. It is upon this feature rather than upon the situation at home that better times for copper must be predicted. At the recent meeting of the Copper Producers Association, John D. Ryan, president of the Amalgamated Copper Co., was elected a member of the executive committee to fill the vacancy caused by the recent resignation of Urban H. Broughton.

The first quarterly report of the Ray Consolidated has just been made public. Production up to October 1 was approximately 9,000,000 lb. of copper in concentrate. At present it is costing the Ray 1½c. per pound to ship its concentrate to El Paso, over what it will cost to ship to Hayden when the new smelter is completed. One-half of the Ray mill is completed and working, and the material for the remaining half is all on the ground. The ore at present being sent to the mill runs about 1.85%. When the mill is running at its full capacity of 8000 tons, the management expects to bring the average of the ore up to 2.17% and copper costs down to below 9 cents.

Horace J. Stevens evidently is inclined to side with J. Parke Channing, in the latter's position that the copper producer will eventually have very much the whip hand. Mr. Stevens, in a recent review of the Lake coppers, says: "For the immediate future, the supply of copper in sight is fully adequate and no unduly high prices need be anticipated; but the figures clearly foreshadow another boom period within the next two to four years, at which time the alarmists will be as badly scared, for fear that the copper supply is petering out as they are now for fear that the production is so much greater than consumption that nothing but permanent disaster is in sight."

That there are others whose faith is as great as that of Mr. Stevens in the future of copper, is shown by the mines which are being made in distant lands. The Alaska copper country has been very much discussed, in part, because some believed that the Guggenheim interests were securing some deposits that would give them permanent control of the market; in part, because some of the ground was made the basis for some very unsavory promotions. The Cerro de Pasco, controlled by James B. Haggin, J. P. Morgan, and the estates of H. McKay Twombly and D. O. Mills, it being rather a family affair, with all of the gentlemen mentioned under one roof in the Mills building in New York, has been much talked of, because it cost its owners some $20,000,000 to bring it to its present state of profitable production. The Braden, the property in Chile, South America, taken up some time ago by the Guggenheims, has just joined the ranks of the producers. The last mentioned mines, one in Chile and the other in Peru, are soon to have each a rival, in the Ferrobamba in Peru and the Chuquicamata in Chile. These properties have been taken in hand by Albert C. Burrage, the Boston copper magnate. Each is said to be an immense steam-shovel undertaking, with orebodies like that of the Chino, exposed so that work can be done with little or no stripping of overburden. Mr. Burrage is the Boston director of the Amalgamated Copper Co., but it is stated that the Amalgamated has no interest whatever in either venture, the interests which have been acquired having been taken over for Mr. Burrage.

Ray Central has been a market feature in the copper list, on the strength of the company's plans for a mill. The present plans include the construction of a plant to handle 1500 tons per day, which will be designed by H. Kenyon Burch, who designed the Montezuma mill at Nacozari and the Miami mill at Globe. Frank H. Probert is acting as consulting engineer. Greene Cananea is beginning to show the results of the rebuilding of its plant. The October production showed 4,058,000 lb. of copper, 127,568 oz. of silver, and 763 oz. of gold. The precious metal values at the Greene Cananea are increasing and are of much importance in maintaining a low copper cost. The mine is keeping within the 9c. cost reached some time ago. The management states that dividends could be resumed now, but distributions probably will be deferred until there is more incentive to production. Any fractional advance in copper means a great deal to a big producer such as Greene-Cananea, and stockholders can really afford to wait for an improved metal market.

Nevada Consolidated is making a unique record in that it is turning out copper at 6.84c. per pound from ore that averages 1.7% copper. The construction of the new smelter to be built at Jerome by W. A. Clark for his United Verde property will be in charge of J. B. McIntosh, who superintended the construction of the International Smelting & Refining plant at Tooele and the new works at the Garfield smelter. The new plant is to be an oil burner and will be situated about six miles from the mine, with which it will be connected by a new narrow-gauge railway line. The erection of the new plant to be built by the Granby on its Hidden Creek property will be in charge of Albert Trotter, who was formerly on the Guggenheim staff. Detailed plans are now in preparation, but actual construction work will not be commenced until in the spring. Expenditure is expected to be about $1,500,000, the plant to be of 2000-ton daily capacity.

SALT LAKE CITY, UTAH

Grand County Uranium.—Ore Deposits Arouse Interest Abroad.—Magna and Arthur Plants Increase Tonnage.—Transportation Contracts.

Developments in the uranium property owned by W. L. Fitzgerald and Louis Grundhand, of Salt Lake City, in Professor valley, Grand county, about 22 miles south of the Denver & Rio Grande railroad, indicate that ore may soon be mined here on a commercial scale. Assays show 3 to 28% uranium, with indications of pitchblende. One analysis said to be of an average sample, gave as follows: Uranium, 2.84%; tungsten or wolfram, 2.84%; molybdenum, 1.72%; thorium, trace; gold, trace; silver, 2 oz. per ton; copper 27%. Several samples have been sent to various scientific laboratories, including the Sloane laboratory at Yale, and a shipment of 100 tons is being forwarded to Paris in response to requests resulting from the analysis of smaller samples. The ore occurs in a red Jurassic sandstone, a light standstone, and in a porphyry intrusive. The higher grade ore is carnotite, chiefly, and the lower grade is largely composed of uraninite.

At the present time the Magna concentrating-plant is treating an average of 12,000 tons of ore per day, and the Arthur about 3000 tons. If this rate of production is continued, it will increase the tonnage for the last quarter of the year still further, to about 1,365,000 tons. The amount of actual copper produced will, of course, depend on the grade of the ore mined during the quarter.

The Utah Metal Mining Co., which is constructing a tunnel through the range at Bingham, connecting with the International Smelting & Refining Co.'s plant at Tooele, has made a contract with the Bingham-New Haven for the transportation of that company's ores through the tunnel. The company has built over a mile and a quarter of the tunnel and has less than a mile left to construct. Several other companies are planning to make contracts for deep mining and transportation through the tunnel.

Utah metal mines have paid to date $5,169,687 in dividends in 1911.

General Mining News

ALASKA

Copper River District

Reports from Cordova state that the production of the Circle City district this year will be between $350,000 and $400,000. Clarence Barry on Eagle creek, Jenson & Herrington, the Mastodon Hydraulic Co., and P. J. Anderson on Mastodon creek, and Berry & Lamb on Mammoth creek are working with full forces and are making big clean-ups.

Ketchikan

(Special Correspondence.)—A No. 9-A Cameron sinking pump is being erected at the Red Wing group, owned by the Prince of Wales Mines, Ltd., and shipping will be resumed in the near future at this property. The mine is equipped with a compressor, three machine-drills, and a 60-hp. boiler. The ore assays 7 to 22% copper and carries gold and silver worth $7 to $9.65 per ton. Ore will be shipped to the Tacoma smelter. Rich ore has been discovered recently. The mine has so far been operated by lessees, but Tola Wyman recently returned as superintendent, and the property from now on will be operated by the owners. It is situated south of the Sulzer group of mines, which are steady shippers.

Copper City, October 26.

Prince William Sound

By a curious coincidence, work started on the Cameron-Johnson properties and the death of Mr. Cameron occurred at the same time, October 29. A shipment of 1500 lb. of ore recently was brought to Valdez. Two tests were made. One sample assayed $343 per ton and a second $1226 per ton.

Drake & Westbrook will continue development throughout the winter. Near the Treasury Note is a good water-power site, suitable for prospecting machinery. Drake & Westbrook hope to ship at least 100 tons before snow disappears in the spring, state advices from Valdez.

ARIZONA

Pinal County

(Special Correspondence.)—The new mill and smelter town of Hayden, in the Gila valley, 21 miles from Ray, is the scene of great activity, there being 1500 men, mostly Mexicans, employed, 700 by the Ray Con. Copper Co. and 800 by the A. S. & R. Co. Four of the eight units of the concentrator are in operation, and equipment and machinery is being installed in the other four units. It is expected that the fifth unit will be running by December 1. While one unit has handled as much as 1350 tons of ore per day, the present average daily tonnage is 900 per unit, or a total of 3600 tons, with a daily production of 180 tons of concentrate, the ratio of concentration being 20 into 1. The concentrate is dried by vacuum-pumps to about 9% moisture and shipped to the El Paso works of the A. S. & R. Co. The recovery of the copper content of the ore is reported to be from 70 to 75%. Electric power is furnished by the power-house nearby, 400 kw. being required for each unit. Water is pumped from the bed of the Gila river a distance of three-quarters of a mile, and 5.6 tons is used per ton of ore. Railroad communication is established by a spur from the Phoenix & Eastern, a branch of the Southern Pacific. About 200 men are employed in the operation of the four units—Americans for foremen and skilled labor, the majority of the workmen being Mexicans. Including the men employed in construction and in the power-house and shops, the total force numbers 700 men. H. Clay, formerly mill superintendent at Cananea, is superintendent.

The fourth generator has been installed in the power-house and the equipment now consists of four Allis-Chalmers 1750-kw. alternating-current generators, each driven by an Allis-Chalmers 4-cylinder triple-expansion condensing engine. There are also two Allis-Chalmers 200-kw. direct-current generators driven by Nordberg tandem compound engines, a Nordberg high-duty 3-cylinder triple-expansion pump with capacity of 7000 gal. per minute against a 90-ft. head, and a Nordberg cross-compound blowing engine with capacity of 18,000 cu. ft. of free air per minute. The pumping-plant on the Gila river consists of three Aldrich quintuplex motor-driven pumps with total capacity of 10,000 gal. per minute.

The A. S. & R. Co. is employing 800 men and is using 425 head of mules and horses, and one steam-shovel on the excavation for the new smelter at Hayden. Their contract with the Ray Con. Copper Co. calls for the completion of the smelter and the beginning of the smelting of the Ray Con. concentrate by April 1, 1912.

Globe, November 8.

The Ray Con. Copper Co., in a report covering the period from the last of April to October 25, just issued, states that before the first of the year the gross output of 2,500,000 lb. of copper per month will be increased to almost, if not quite, 3,000,000 lb. per month. Up to October 1 the production of copper in concentrate has been at a rate of about 9,000,000 lb. per month. Since the April report 47,240 ft. of workings has been driven, and several drifts and adits have been enlarged for permanent working. The concentrator building, power-plant, shops, and all accessories at Hayden have been completed. The fifth unit of the plant, which is to be completed at an early date, will not be needed before the end of the year. The water-supply is said to be unlimited as far as present or possible requirements are concerned. In the future the company will issue quarterly reports.

Yuma County

At the Steece Copper M. Co.'s property, according to recent reports from Parker, the shaft at the 500-ft. level passed through about 80 ft. of ore which assayed on the average $20 per ton. The shaft is now 900 ft. deep. Cross-cuts will be run to determine the width of the ore-body. P. H. Newman is superintendent of the property.

CALIFORNIA

Calaveras County

(Special Correspondence.)—The shaft at the Lightner mine is down 525 ft., with cross-cuts extended from the 200, 300, 400, and 500-ft. levels. It is reported that six distinct shoots have been opened, and the 60-stamp mill is running in good ore. The company treats its concentrate at its own chlorination plant, the product being sent from mill to works by an electric aerial tramway. It is reported a mine telephone system is planned. At the Angels group the old 900-ft. Angels shaft is being sunk deeper. A pump has been installed. The Melones Mining Co. temporarily has suspended operations, pending repairs and improvements to the surface plant. A 1600-ft. ditch will be built to enlarge the water-supply system, and the mill will be overhauled. A 250-hp. electric hoist is being erected. This mine is one of the most economically operated on the Mother Lode. The ore is quarried, and reduced by a 100-stamp mill. The property is on the north side of the Stanislaus river.

Angels, November 10.

Eldorado County

Ore assaying $82 per ton has been discovered in the Lucky Baldwin mine, recently acquired by Los Angeles investors, and the working force is being increased.

San Francisco capitalists have acquired the Beebe mine, near Georgetown, and extensive development is planned.

Plumas County

Another copper discovery has been made near Portola by Jack Rankin, who made the first find. Rich peacock ore was found in the second discovery, which was made about three miles from the town of Portola. Rankin sold his third interest in the first discovery for $15,000, state recent press reports. While many prospectors have been attracted by the copper discoveries, few locations have been made, as the finds were on patented land.

Sacramento County

Dredge No. 8 of the Natomas Con. of California, which was burned October 20, is to be rebuilt at a cost of about $225,000, according to recent reports.

SHASTA COUNTY

(Special Correspondence.)—The Mammoth Copper Co. is driving a new adit which will be used as the main working level. It lies about 750 ft. southeasterly of the main adit and is about 2000 ft. long. It is 9 by 10 ft., and is planned to intersect the orebodies about 167 ft. below the present workings. At the 2400 ft. level, it is believed, a new vein will be tapped, while at the 3100 ft. level the main orebody should be reached. Driving is progressing at a rate of 14 ft. per day. Two machines are employed, and 25-ton cars will be employed to transport ore, the cars being operated by electric motors. The track is laid with 50-lb. T-rails with a 36-in. gauge. It is planned eventually to extend the adit 600 ft. farther to tap a virgin vein disclosed by the diamond-drills. It is rumored here that the Bully Hill Copper Co. is still experimenting in an endeavor to devise a smelting process which will overcome the fume annoyance. The company's plant at Delamar has been idle for 18 months owing to the action of the National Forest officials. The Mt. Shasta has completed a new station on the sixth level, and driving from this and the fifth level is under way. Twelve men are employed. H. A. Clark is manager. The Mt. Shasta lies eight miles west of Redding. During October the Delta Con. company shipped two cars of silicious quartz to the Mammoth smelter. S. D. Furber, assistant secretary, is directing operations. The Minne Shasta recently sent a car of fair-grade ore to the Mammoth smelter. The mine lies in the Middle Creek section. The Noble Electric Steel Co. is completing the new furnaces at the Heroult electric iron smelter. It is reported active production will commence shortly.

MAMMOTH SMELTER.

Kennett, November 11.

SIERRA COUNTY

Rich ore is reported to have been found recently in the Sixteen to One mine at Alleghany, according to recent newspaper despatches, but no definite information has been given out.

TEHAMA COUNTY

The Northern California Gold Mining Co. will soon have its suction dredge in operation, it is reported. The dredge will operate about ten miles from Red Bluff.

TUOLUMNE COUNTY

(Special Correspondence.)—Operation has been started at the Starr King mine. The new 5-stamp mill is working satisfactorily, and it is believed that sufficient ore can be extracted in development work to keep it working steadily. Where work is now being done the vein is large and of a fair-grade ore, with a streak of high-grade that should bring the results up to a satisfactory average.

The Iron Spring and Buster mines, situated in Hunter canyon and owned by Benjamin Darnert and D. J. Sutton, have been bonded to S. O. Prescott, who is also interested in other East Belt mining properties. A crew immediately will begin driving an adit 500 ft. Mr. Prescott is the owner of several quartz claims in the same district as the properties he has just bonded, and he will begin the development of these in the near future. A bar of gold weighing 70 oz. is the result of the first clean-up after a 30-day mill run at the Crystalline mine. A large quantity of sulphide also was saved. Repairs are being made to the plant at the Omega.

At the El Dorado mine, near here, a 4-ft. vein showing free gold has been uncovered in an old shaft north of the prospecting shaft lately sunk and in which a small vein of high-grade ore was found several days ago. The property is being developed by the owners, the Sivori brothers and Henry Rosasco.

Development may soon be resumed at the Miller mine, in which R. W. Canthers of Sacramento is interested. Good progress is being made in the Columbia basin project, the double-compartment shaft having reached a depth of nearly 150 ft. Thus far the flow of water has been easily handled with one small pump, but four 10-in. pumps are being installed in anticipation of a large volume of water when bedrock is reached. Some of the gravel strata already traversed are gold bearing. Though a station has been cut at the 100-ft. level, it is understood that no driving will be done before the bottom of the shaft is on bedrock.

Tuolumne, November 12.

Conlin brothers, operators at Rye Patch, Nevada, have secured a bond and lease on the Golden City quartz mine and have started operations.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—Work has been resumed on the Everett property, situated on Republican mountain. Otto Shatz, of Denver, is operating the mine under bond and lease. The Terrible compressor-plant is furnishing air for the operation of machine-drills at the Seven-Thirty and Zero mines. Shipments of lead and zinc ore are to be started from the Key West mine on Leavenworth mountain. The orebody is from 7 to 14 in. wide. E. J. Butts is manager. Plans have been completed for the resumption of work on the St. Paul property. The adit will be driven 500 ft. to intersect the St. Paul vein. Mont Tong is manager. A 12-in. streak of quartz that assays $40 per ton in gold and silver is showing in the bottom of the 35-ft. shaft sunk on the Black Prince vein. F. Winters, Jr., is owner. Construction work on the new mill at the Conqueror mine on Covode mountain will be started this month. George Schneider is manager. Work has been resumed on the Old adit situated in Columbia mountain. The bore is now in 550 ft. and a vein should be cut in the next 20 ft. The Mineral Chief mill is now running on three 8-hr. shifts. An average of 60 tons per day is being treated. A. L. Stephens is manager of both mine and mill. Work will be resumed in a few days on the Central Colorado property on Leavenworth mountain. C. R. Iliff of Denver is owner. Occasional shipments are being made from the Amie mine, returns of $90 per ton in gold and silver being received in settlement. W. S. McGintie is manager.

Georgetown, November 11.

GILPIN COUNTY

A mass of pitchblende or uraninite, weighing 240 lb., it is reported, was recently taken from one of the uranium producers on Quartz hill in Gilpin county. This pitchblende surpasses in radioactivity the pitchblende produced in Austria, but has not yet been developed in large bodies. Small but rich pockets are occasionally found in the development of the other ores for which the mines are worked. Similar ore, it is reported, has been shipped in the past from the Jo Reynolds mine in Clear Creek county.

Shipments assaying $120 per ton are reported from the Corydon, a mine that has been idle most of the time for twenty years. The property is owned by Henry M. Teller and associates, of Denver. Shipments reported from the Pittsburg in Russell gulch returned $325 per ton for the first-class ore, and $225 per ton for the second class. The ore was taken from the 800-ft. level and preparations have been made to follow it to greater depths.

LAKE COUNTY

Arrangements have been made to take advantage of the proffered co-operation of the Central Colorado Power Co. in providing for the unwatering of the lower depths in the mines of Carbonate and Fryer hills. A company with a strong directorate will assume charge of the pumping operations. The $40,000 that this company will need for the purpose will be raised by the sale of securities. The power company will subscribe $15,000, to be paid in current at a rate that will make the pumping much less expensive than it would be if coal were used. Liberal subscriptions from the mine operators and other business men of Leadville are assured. The deepest mining now in progress on Fryer hill is not more than 500 ft. from the surface. By raising about 700 gal. per minute it is estimated that the water-level can be lowered to 700 ft., and large bodies of zinc carbonate made available for profitable production. By pumping 1200 gal. per minute on Carbonate hill the water can be lowered to 1300 ft. from the present depth of 1000 in the Wolf Tone. The ground to be unwatered contains deposits of complex sulphide ores from which a large production can be maintained.

Walter W. Davis, formerly of the Yak adit, has gone to Aspen to take charge of the Smuggler properties, which have been unwatered by pumping through the Free Coinage shaft.

OURAY COUNTY

To promote prospecting in the Ouray district the Telluride Power Co. has offered to supply power to prospectors at one-half rates for long-time mining contracts.

TELLER COUNTY (CRIPPLE CREEK)

Work will be resumed at the 1000-ft. level of the El Paso mine in the near future. Development was abandoned some time ago through the flooding of the mine. With the increased production made possible by this work, it is believed that the company may resume the quarterly payment of dividends. Sinking of the Nichols shaft is progressing well. It is planned to give this shaft an additional depth of 300 ft., which will permit the El Paso company to hoist ore from the deep levels of the Beacon hill Ajax property. John Nichols is superintendent for the company.

IDAHO

SHOSHONE COUNTY

William Beaudry, superintendent of the Stewart mine in the Coeur d'Alene district, has confirmed the report of the recent ore discovery, saying that the vein was found in the winze and that it may go farther than the winze. The miners are reported in ore at a depth of 185 ft. The opening of the new orebody will greatly increase the shipments of pure galena. The long adit is being driven at a rate of about 400 ft. per month, and unless more than usual difficulties are met with in crossing the Osburn fault, the orebody should be reached early next spring. The crew has been enlarged and three shifts have worked continually, with results which, it is said, have set a record in the Coeur d'Alene.

MONTANA

DAWSON COUNTY

J. W. Ridinger, of Coeur d'Alene, is quoted at Spokane as saying that Ridinger & Co. will erect a stamp-mill on their property on Cedar creek, for operation in July. Much development work has been done on the property and assays have been secured ranging from $30 to $500 per ton. The ore is refractory, carrying copper, silver, lead, and running high in gold. The company has five claims. A 50-ft. adit has been driven on one of the claims. The company plans to handle the free-miling ore at the property and to ship the concentrate to the smelter.

LINCOLN COUNTY

(Special Correspondence.)—The Dominion mine, situated at the head of Lyons creek, near the Lincoln-Sanders county line, has a vein of ore about 4 ft. wide, rich in gold, according to William Criderman, who recently visited the property. The vein has been opened up for a distance of 1400 ft., Mr. Criderman says, and a series of assays taken at different places along the vein for this distance gave returns ranging from $9 to $1700 per ton in gold. In specimens taken from the property the free gold is plainly visible. The mine is situated on the divide between the headwaters of Vermillion and Silver Butte Fisher creeks. It is being developed by a company organized at Hamilton, and supplies have been taken in to last throughout the winter. Mr. Criderman has a claim on a vein parallel to the Dominion upon which he intends to do some work at once. The first move will be the letting of a contract for an adit 150 ft. long, which will cross-cut the vein at a depth of 100 feet.

Libby, November 8.

SILVERBOW COUNTY

(Special Correspondence.)—A large number of stockholders of Butte Coalition in this city were in favor of the proposal which originated somewhere in the East of a dividend being declared from the treasury surplus, but the cool-headed ones are wondering how a dividend of $4 can be declared on 1,000,000 shares from a treasury surplus which is less than $4,000,000. It is feared that the story originated in the mind of some Boston broker who took this means to start a boom in the stock. If this were the object, to some extent it has been a success. However, if this dividend is paid, the holders of the stock cannot expect to receive more than $3.80 per share, as the treasury surplus amounts to $3,850,000. Since Butte Coalition sold its property to the Anaconda company it is nothing more than a holding company, but it holds a large amount of stock in the Anaconda Copper M. Co. and the International S. & R. Co. The income from stocks held is adding something over $50,000 per year to the treasury after all expenses and dividends are paid.

The men who a few months ago made such an effort to raise sufficient money to build an independent smelter have abandoned the effort, and those independent owners have found out that people are not going to put their money into any such enterprise when the smelter accommodation at present is much more than sufficient to handle all of the ore offered and thousands of tons besides.

Butte, November 13.

NEVADA

CLARK COUNTY

E. Carleson and Charles W. Lund will start development immediately on a lease they have secured on 400 ft. of the main Quartette vein, says a report from Searchlight. The lease includes the original Quartette shaft, sometimes known as the glory hole.

The Searchlight M. & M. property temporarily has been shut down. Additional pumping facilities will be provided, according to a statement of H. E. Carter, manager of the property. The mill may start, however, in a few days on a run of ore from the Wells lease on the Dabu claim.

C. J. Farr, Charles Fearney, and George Weeks have started development in the Leadville district, 25 miles south of Searchlight, and plan to ship to the smelter at Needles.

ESMERALDA COUNTY

High-grade ore is being sacked for shipment at three points on the claims of the C. O. D. Consolidated, state recent press reports. Ore assaying about $300 per ton is being mined in a drift from the old incline that connects the workings of the Gold Bar and Victor mines.

Development will be resumed in the near future on the Jackpot group, about four miles west of Goldfield, according to recent reports. A trust deed covering a bond of $200,000 from the Hall Jackpot M. Co. to the Merchants Bank & Trust Co. of Los Angeles has been filed.

The directors of the Montana-Tonopah company recently ratified the purchase of the Commonwealth mine, near Pearce, Arizona.

The shaft of the Florence mine is down 915 ft., and sinking is being continued in order that new ground at a greater depth may be developed.

HUMBOLDT COUNTY

E. W. Hawk has discovered ore assaying as high as $1500 per ton on the Delaware M. Co.'s property in the Seven

Troughs district, according to recent reports from that place.

Active development is to be rushed on the Seven Troughs Monarch M. Co.'s property, to cut the vein, according to a recent announcement by D. P. [illegible], manager for the company. The adit now is in 1400 ft., and it is believed the vein will be found within the next 100 feet.

W. C. Pitt has purchased a one-fourth interest in the Walker brothers' cinnabar property in American canyon, says a report from Lovelocks. The property is equipped with a Huntington mill, concentrating tables, and retorts.

LANDER COUNTY

The Gold Basin M. Co. recently made the first payment on a group of claims at Carroll, in the southwestern part of the county to Charles Carroll, J. L. Watt, William Watt, and Mrs. Isabel Watt. All remaining Watt and Carroll properties are to be offered for leasing.

LYON COUNTY

(Special Correspondence.)—Business from a mining standpoint is improving in this vicinity. Unusual activity is noticeable along the copper belt, caused by the work nearing completion on the smelter at Wabuska.

SEVEN TROUGHS IN 1908.

Many of the silicious gold prospects have from a few hundred pounds to several tons of a medium ore that will not stand shipment to San Francisco or Salt Lake City, which will pay a profit when the new smelter is blown in. The majority of these prospects are on small seams and veins, and will never be large producers. On account of their smallness it will not pay to follow them to any great depth.

Yerington, November 11.

NYE COUNTY

The Tonopah M. Co. last week shipped 3450 tons, the Belmont company 2650 tons, the Montana-Tonopah 1045 tons, the Tonopah Extension 987 tons, the West End 525 tons, and the Midway 50 tons, making the total production for the district 8707 tons, the estimated value being $217,675, states the *Tonopah Miner*.

STOREY COUNTY

Only a nominal production was made by the Comstock mines last week, partly through the fact that no stoping was done on the 2500-ft. level ore. The Ophir, however, approached its customary output with 282 tons, which averaged about $50 per ton, the total production from the mine being valued at $14,252. The Crown Point, owing to the repairing of the Yellow Jacket shaft, hoisted a comparatively small amount of ore. During the repairing of the 2000-ft. station of the Union shaft, the only mining done by the company was the sinking of the Union and Sierra Nevada winze. At the Mexican, work on the mill was continued, together with other construction work and underground development. Three cars of ore were shipped to the smelter. At the Union Consolidated a higher grade of ore was found on the 2500-ft. level. Fifty-five cars assaying on the average about $24 per ton, and 55 cars assaying on the average about $6 per ton were shipped. The usual repairs were made at the Consolidated Virginia, together with considerable development work. The southwest drift on the 2250-ft. level was driven 16 ft. through low-grade quartz from which 22 cars averaging a little over $10 per ton was saved.

WHITE PINE COUNTY

The Nevada Con. Copper Co. in the quarter ended September 30, according to the official report recently issued, produced 15,837,097 lb. of copper, about the same as the production for the preceding quarter. This fact is taken as an indication that the company is maintaining its production at a figure of about 64,000,000 lb. of copper per annum. For the second time, no mention of costs was made. Thompson, Towle & Co., figuring on 12¼c. copper, computes the cost at 6.84c. per pound. The latter company, commenting on the Nevada Con. report, remarks:

"It is worthy of note that during this quarter the grade of ore treated was 1.7%, copper, which is the average of Nevada Consolidated's reserve. It is not to be lost sight of, however, that operations are confined at present entirely to steam-shovel ores and no underground mining is now being done. The management of Nevada Consolidated feels confident that the cost over the life of the mine will not exceed 7c. per pound. This opinion, however, is not expressed by some engineers, who believe that a 7½c. figure will be nearer the true average."

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Ernestine M. Co., even while erecting the new batteries, necessitating the stopping of ten of the old stamps to permit the new mortar-block to set, made the greatest monthly production in its history in October. The new orebody opened below the main adit is over 20 ft. wide and assays $40 per ton. The last 10-day clean-up in October yielded 10,465 oz. of gold and silver bullion, and 5 tons of high-grade concentrate; 570 tons of ore was milled during the week, producing 50 sacks of concentrate in addition to the zinc-box precipitate. E. Craig, the president of the company, is inspecting the property and the new machinery. At the Deadwood mines the third level west has opened good ore. The mill continues its regular production of bullion and concentrate. Both the old Cooney mine and the Little Charlie, of the Mogollon Gold & Copper Co., are producing a good-grade ore. Smelter shipments are being made from the former, while 10 tons per day are being treated in the Deadwood mill from the latter. The new working shaft on the Pacific, of the Oaks Co., has been sunk 18 ft. in ore. Work continues on the main adit. A good orebody has been opened in the 80-ft. shaft of the Iron group.

Mogollon, November 10.

OREGON

JOSEPHINE COUNTY

Chicago investors have purchased the W. H. Barr placer property, consisting of 320 acres on Briggs creek, state recent reports from Grants Pass. A sawmill will be built and the placer equipment will be added to. Moore brothers leased the property last year, and applied for a renewal, but Mr. Barr decided to sell the property.

As soon as the Commercial club of Grants Pass will give him a site, A. J. McCorkle will erect a 200-ton sampling-mill at that place.

Two carloads of machinery for the mill of the Michigan mine have been delivered. The equipment delivered includes Monell concentrating tables and a Monell slimer, manufacturd in Colorado. A mill may be constructed at the Jewett mine, 7 miles southeast of Grants Pass. Development will be resumed in the near future at the Granite Hill mine.

UTAH

JUAB COUNTY

The South Iron Blossom company recently completed assessment work on the unpatented ground owned by the company in the south end of the Tintic district. The work in the main adit, where the assessment work was done, was encouraging, and as soon as possible in the new year the ground will be patented.

The electric pump at the Swansea, which was stopped by a breakdown, will be in operation in a few days. Work will be taken up on the 940-ft. level.

Negotiations are under way with Salt Lake City mining men for a lease on the Godiva mine.

Salt Lake County

The report of the Utah-Apex M. Co. for the year ended August 31, recently made public in the West, states that regular shipments have been made since April. The mill was put in operation in June and is running two shifts on second-class ore from the Parvenue orebody. Plans are made to mix with this ore from the Louisa adit. An arrangement has been made to load directly on the cars of the Bingham & Garfield railroad near, and on the same level as, the Parvenue adit. The ore-sales for six months amounted to $313,102. The mining costs were $191,802, leaving an operating profit of $121,300. Other expenses amounted to $33,622, leaving a net profit of $87,672.

The Utah-Apex commenced using the Bingham & Garfield railroad on November 10. In six months of mining the company shipped 38,000 tons of ore.

Tooele County

It is believed that two lead furnaces of the International S. & R. Co. at Tooele will be in commission by the first of the year. The foundation work for two of three furnaces has been finished and the work of erecting the furnaces will be started at once. Grading for the third furnace is under way. Over 90% of the structural steel for the storage and bedding bins has been received. The large flue dust chambers have been completed and the bag-house also has been erected. Work on the plant was started last June.

WASHINGTON

Ferry County

(Special Correspondence.)—The Ben Hur Leasing Co. has completed the cross-cut from the shaft to the vein and is timbering the station on the 400-ft. level of the Ben Hur mine. The Knob Hill company shipped four cars of ore from the Knob Hill mine for the week ended November 3. The Quilp is now well ventilated, a new blacksmith-shop has been built, and the old one has been converted into a drying-house. The ventilation affects the 600-ft. level of the Surprise mine, from which the No. 2 and 3 raises on ore afford an air-current through the stopes. A small portable engine has been erected on the main level for hoisting steel, timbers, and supplies.

Republic, November 3.

Robert A. Koontz, of Spokane, president of the San Poil Con. M. Co., announces that the directors have decided to equip the property at Republic with a mill of 125 tons capacity. S. L. Boyer, manager of the mine, reports that in the South San Poil stope, above the No. 2 level, the orebody is from 6 to 8 ft. wide. Samples of the working face show 2 ft. of ore assaying about $135, and 6 ft. assaying $31 per ton. It is from this stope that the company was shipping until compelled to suspend by the closing of the Granby smelter.

Spokane County

L. K. Armstrong, temporary secretary, has called a meeting for November 24 to organize the Spokane section of the American Institute of Mining Engineers. It is planned to give a dinner in the evening. This will be followed by a business meeting, at which papers will be read. Officers for the year will be elected and a formal organization effected. R. S. McCaffrey, of Moscow, Idaho, will be one of the principal speakers.

Stevens County

(Special Correspondence.)—The First Thought Extension mine, in Orient district, idle for several months, will be active about November 10.

The adit of the Blue Grass mine, driven a long distance in barren hard rock, is in 335 ft. and entering vein matter. The Scotia mine has been examined in the interest of New York capitalists.

Orient, November 4.

The Diamond R., Diamond R. No. 2, Bella May, and the Bluejacket claims, in the Metaline district, have been transferred by William Kroll of Spokane and his associates to the Falls City M. & M. Co., which has been incorporated with a capital stock of $2,000,000 for the development of these properties. The ore is silver-lead, with the lead predominating. A crew of men is doing development on the Diamond R. at the present time, and it is planned to do extensive work in the spring.

CANADA

Ontario

(Special Correspondence.)—After the first snow at the Porcupine district comes the warm Indian summer that is new to most of the mining operators there at present. South Porcupine has built up wonderfully since the fire, and the convenience of the electric light is appreciated again.

Work at the Dome mine and mill is progressing as rapidly as material arrives. Nearly all the concrete work is in place at the mill; remaining to be completed is the tube-mill floor, the reinforced precipitation-press floor, and a few column piers. Two Merrill precipitation presses and one Merrill clarifying press will be placed on the reinforced floor. The material for the tube-mills, the presses, and the batteries has arrived, and will be placed immediately. The motors are on the ground and will be placed next. Most of the mill and cyanide tanks have arrived and have been placed. The first carload of steel for the new mill-buildings is delivered. The brickwork for the camp buildings has been finished and that for the machine-shop and store-house is nearly done. The refinery will be started in a day or so. The steelwork is about half up on the power-house, four of the present six boilers are ready, although one is sufficient to run the 12-drill compressor. Underground work is being rushed.

Sanitary conditions at the Dome mines will be most modern in every detail. They are installing a septic tank for sewage disposal to eliminate typhoid fever and other ill effects from unsanitary methods.

The spur track from Porcupine has been an important aid to the rebuilding of the surface plant. The company stock-yards show well with lumber, coal, and brick. About 20 carloads of steel is yet to arrive.

South Porcupine, October 29.

MEXICO

Chihuahua

Goldman & Co., of Mexico City, have purchased the Esperanza property, in the Placer de Guadelupe district, from Julio Miller and Jesus Madrid for $40,000, states a recent report from Chihuahua.

Shipments are being made to the A. S. & R. Co.'s smelter at Chihuahua from the Buena Tiera, Santa Eulalia, which was purchased last year by the Exploration Company of London for $600,000. R. M. Ray is manager for the company.

A record for shaft-sinking in the Santa Eulalia district has been established by sinking the shaft of the Estella mine over 100 ft. in the last month. The shaft, which now is 185 ft. deep, is 6½ by 15 ft. W. T. Swoyer is manager of the property, which is owned by Bainbridge, Seymour & Co. of London. S. G. Burn was the contractor in charge of sinking the shaft.

Sonora

The Greene-Cananea smelter established another record for itself in its October production, 6,000,000 lb. of blister copper. A third of this was from concentrate shipped by the Miami company, the customs product bringing up the output to record size. The Greene-Cananea company, during the month, had a little labor trouble, and the Oversight mine was closed for seven days, although the curtailment is not apparent in the smelter's production.

At Agua Prieta the records show the October exports to the United States amount to ₱1,169,500, divided as follows: copper, ₱463,800; silver, ₱427,100; gold, ₱178,600. There were 244 cars, containing 9433 tons of ore. The El Tigre mine shipped 78 bars of bullion, weighing 6340 lb. and valued at ₱95,000.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press

Injury to Miner Safety Cages

The statute of Montana requires iron bonneted safety cages with doors, in mine shafts over 300 ft. deep, to be used in lowering and hoisting the miners. The provision that the doors must be closed "when lowering or hoisting the men," must apply to the singular number as well as the plural, and requires the closing of the doors during the hoisting or lowering of one or more miners. The statute was not complied with by closing the doors only when the shifts of men employed in the mine were being lowered and hoisted at the usual time of changing the miners. And where the statute provides that when the cage is used for sinking only, it need not be equipped with such doors, the term 'sinking' is not technical but means descending, going down, excavating downward without substantial deviation from a straight line, and does not include the cutting of stations so as to relieve the operators from providing doors to such cages during such operations. Evidence in the trial for an injury to a miner while in such cage, showing that he entered the cage from a station from one side and that his foot got off or over on that side where it was crushed, was sufficient to show that his foot extended out of the cage through an opening where there should have been a door, and made it clear that the absence of the door from the cage was the proximate cause of the injury.

Osterholm *v.* Boston & Montana Consolidated Copper & Silver Mining Co., (Montana) 107 Pacific, 499.

Injury to Miner—Negligence of 'Shift-Boss'

The statute of Montana makes a mining corporation liable for injuries to a miner if such injury is occasioned by the negligence of a superintendence of a superintendent, foreman, shift-boss, engineer, or crane-man. Under this statute the word 'shift-boss' is formed by uniting the words 'shift' and 'boss'. The word shift means a set of workmen working in turn with other sets, or the time during which a particular set of men worked; and the term 'boss' means a master workman or superintendent, a director or manager, or one who oversees and gives directions; and this compound word as used in the statute accordingly means a master workman who directs the work of a set of men engaged on a particular shift. And in an action by a miner for an injury alleged to have been caused by the negligence of the shift-boss, the plaintiff was entitled to the admission in evidence of a paragraph of the defendant's verified answer, which after denying that the miner was injured while engaged in his duties as defendant's servant, or that the person by whose negligence he was injured was a fellow servant of the defendant, in fact, or was acting as shift-boss for defendant, alleged that the miner was injured through the negligence of one of defendant's employees, who was then and there a fellow servant of such injured miner, as such allegation was proof that the miner was injured by the negligence of one of the defendant's employees. But where it was alleged that the injury to the miner was by the fall of certain timber from above, the question of negligence must be submitted to a jury where there is any evidence to support the theory that the timber was caused to fall by the negligence of another servant in charge of the shift at the time of the accident. Under this statute it is not essential to render the master liable that the negligence of the shift-boss should obtain by the performance of a non-delegable duty owing by the operator of the mine, but the statute was intended to create a liability for the negligence of such superior servant resulting in injuries to another servant, though the negligence was occasioned while such superior servant was performing ordinary labor, not superior in grade to that of the miner injured.

Johnson *v.* Butte & Superior Copper Co., (Montana) 108 Pacific, 1057.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the Mining and Scientific Press.

The Theory and Practice of Technical Writing. By Samuel Chandler Earle. 301 pp., ill. The Macmillan Co., New York, 1911. For sale by the *Mining and Scientific Press.* Price, $1.25 net.

A more general realization of the actual importance of technical writing in the field of literature is exhibited by the numerous articles and volumes upon the topic that have appeared during recent years. The present volume is obviously intended for a textbook, and will be of service to the technical schools where the study of English is included in the curriculum in a belated endeavor to correct the deficiencies of matriculants. Teaching 'technical writing' rather than good English is as unsatisfactory as teaching 'practical' surveying without mathematics. But a half loaf is better than no bread. There is much in Mr. Earle's volume that will be of service to those who feel their literary deficiencies, though so detailed a discussion is likely to prove discouraging. And we cannot agree with Mr. Earle in his division of writing into literature and science; the purpose of the former being to please, and of the latter to instruct. No such line of division exists; the great novelists have instructed as well as pleased, and the great scientists have pleased as well as instructed. Technical writing should possess all the characteristics which Mr. Earle discusses at length in his pages, but it should also possess the merit of pleasing literary form, which is a potent aid in attracting and holding the attention of the reader. Spencer has defined good conduct as that which is well adapted to secure a worthy end. Similarly good writing may be defined as that which is well adapted to attain the desired end. The end may be a simple one, more often it is complex and the characteristics exhibited will be similarly complex. Good writing is an art, and like other arts, a foundation of natural aptitude must exist upon which training may be superimposed.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. W. MERRILL has gone East.

FRANCIS DRAKE has gone to New York.

HERBERT S. JOHNS, of Oroville, is in San Francisco.

C. G. ROTHSCHILD, of New York, has gone to London.

E. A. RITTER is in Utah investigating carnotite deposits.

DEAN E. MITCHELL is expected to arrive from England shortly.

KARL EILERS and D. J. ROBERTS visited Globe, Arizona, last week.

A. H. CARPENTER has returned to Denver from Wyoming and Nevada.

J. E. HALL, of Reno, Nevada, is staying at the St. Francis hotel, San Francisco.

J. H. WEDDLE was in San Francisco and has gone to Choluteca, Honduras.

A. J. HOSKIN, of Denver, is engineer for the Moore Mining Co., at Alma, Colorado.

A. C. PERKINS has been examining dredging ground in the Perm district in Russia.

H. W. TURNER is making a geological study of the Ufalei estate, near Ekaterinburg, Russia.

M. L. REQUA is in New York and is not expected to return until the end of the month.

GASTON CLAUS, of Paris, was in San Francisco recently and has gone to Folsom and Oroville.

F. G. COTTRELL has left for the East, where he will confer with the Director of the Bureau of Mines.

CHARLES W. BOISE is on his way from Hurley, New Mexico, to Kinchasa, Belgian Congo, West Africa.

E. D. MCDERMOTT has returned to London, having resigned his position at the Kyshtim mines in Russia.

KURT PIETRUSKY has returned from abroad, and will be in New York City, instead of Chicago, as formerly.

J. C. WILLIAMSON, of the Orsk Goldfields, Ltd., was in San Francisco recently, and has sailed for Yokohama.

ROBERT E. CRANSTON has recently returned from Oregon, where he made an examination of the Oriole mine near Grants Pass.

SAMUEL W. OSGOOD, of Osgood, Carter Co., Chicago, will be in Knoxville, Tennessee, district for some weeks, examining zinc properties.

HORACE V. WINCHELL recently made an examination of the Idaho-Maryland mines at Grass Valley, California; he expects to go to Idaho and Montana.

K. C. PARRISH will sail from New York on November 24, for Cartagena, Colombia, South America, and will probably not return until next summer.

LEIGHTON STEWART, of Summerside, P. E. I., Canada, will be in the future with the American Smelting & Refining Co., at Tiro General mine, Charcas, San Luis Potosí, Mexico.

AMBROSE MONELL, of the International Nickel Co., W. E. COREY, late president of the U. S. Steel Corporation, and E. C. CONVERSE, of the Bankers Trust Co. of New York, were at Porcupine last week.

J. O. ROYER and LEOPOLD GELUS, general manager and president, respectively, of the Quartz King mine, left Parker, Ariz., recently, for Los Angeles, together with F. G. STIERLIN, engineer for the Chamber of Mines, Marseille, France.

FREDERICK F. KETT has been appointed general manager for the Swedish Iron Mines & Furnaces, Ltd., with headquarters at Nora, Sweden. For several years Mr. Kett was in charge of the 100-stamp mill at the Melones mine in Calaveras county, California, and recently resigned from the position of mill superintendent for the Braden Copper Co., in Chile.

BOSTON news despatches relate that the Essex Hosiery Company has taken over the Brown Stocking Company. But what has happened to the blue stocking?

JAPANESE SULPHUR from Hokkaido will hereafter be admitted free of duty, as the Treasury Department has reversed its recent ruling that the process by which this sulphur is produced is a refining process, within the meaning of the act imposing a duty of $4 per ton on refined sulphur.

SUPREME COURT decisions, under a new ruling cutting down the time allowed for arguments, will be much expedited and the number of cases disposed of this year will greatly exceed last. When the sensible arrangement of preventing an appeal upon technicalities of procedure, where substantial justice has been done, is put in force even greater progress will be made.

ORE DEPOSITS are objects of unceasing study and the sources of perpetual interest. And when they are discussed by so clear a thinker and lucid a writer as Mr. James Furman Kemp the interest is doubly intensified. Mr. Kemp is so closely identified with the present-day recognition of the importance of the rôle which igneous rocks have played in the formation of veins that the interest of his exposition of contact deposits, given elsewhere in this issue, is outdone only by its importance.

CONDITIONS in Mexico are still unsettled, and the recent action of the United States Government in seizing the person of General Bernardino Reyes, as well as a quantity of arms and ammunition, has served to attract attention to the real situation. Continual agitation in Mexico can serve no good purpose and may wreak much harm. Until Francisco I. Madero has had opportunity to show his ability as president, outbreaks against the Government are childish folly. And if a change of leadership should later appear desirable, legitimate opportunities of making it will not be lacking.

AUTHENTIC news from China has been scanty recently, and the final outcome is as uncertain as ever. Yuan Shih-kai has finally accepted the premiership, announcing that there is no hope of establishing a republic so promptly and effectively as to forestall foreign intervention. This care to prevent giving any occasion for foreign interference has marked all the actions of both sides throughout the progress of the outbreak, but if unrest prevails too long in the Flowery Kingdom the resultant effect upon national finances that have for years been in a precarious condition is likely to prove serious.

LEGISLATION that is hasty is often correspondingly irrational. No better example of this could be desired than the employers liability law recently enacted by the legislature of California. Under its provisions the employer of a reckless chauffeur who demolishes himself and his employer's machine in a collision, would be liable for whatever sum a jury might be persuaded to fix as the value of his life. Any employer of a single servant is similarly liable for injuries not within his power to prevent. Legislation of this character undermines the foundations of government by eradicating popular respect for the law-making branch.

ENGINEERING courses at Columbia University are to be placed upon the plane of graduate work, requiring two years of college work as a prerequisite, following the recent recommendation of the president and faculty. Many engineering students have failed to derive from their technical courses the benefit they should, because of the immaturity of their minds, or lack of adequate preparation. Students who find it imperative to become salary earners as early as possible can always find schools to meet their need. Columbia University, which, it is interesting to note, has the largest number of students of any university, does well to set the highest standards for itself.

The Alaskan Situation Again

Too protracted discussion, colloquially designated as 'Fletcherizing the conversation,' is the mark of the bore, and, having stated our views regarding Alaska and its problems, we have refrained from tiresome iteration. The Chicago address of the Secretary of the Interior, Mr. Walter L. Fisher, has received such wide publicity, and so nearly coincides with our previously expressed views that we at first refrained from its publication. But since it has, in some quarters, appeared in garbled form, we present it this week, as nearly in full as consideration of space will permit. A feature of the address that calls for further comment is the suggestion that the railroad from Seward should be constructed to the coalfields, and that if private enterprise does not undertake it the Government should do so. Recognizing the strength of the sentiment against the Government operation of public utilities, Mr. Fisher further suggests that joint public and private ownership and operation may be found practicable. The uncertainty of early returns upon the investment is likely to deter private capital from engaging in such a joint enterprise, and it might be well for the Government interest in such an enterprise to guarantee to the private investors, for a term of years, a reasonably low rate of interest upon the capital invested. There is too much fuzzy thinking and useless discussion in regard to Alaska. What is needed is prompt results, not comminuted conversation. Private individuals have finite lives and desire to reap returns upon their investments in this generation, the Government is under no such necessity and can afford to operate a railroad at a loss for twenty years if the assured returns for a century justify such a course of action. There is too much of the philosophy of unreason in what is put forth in many quarters in regard to Government ownership and operation of public utilities and resources. The universal control and operation of mines and railways by the Government is unquestionably undesirable. But Government control and operation of a few mines and railroads in districts where conditions are favorable is unquestionably desirable, so that we may be able to discuss its advisability from the standpoint of accurate information, not that of blind prejudice. The advisability of the leasing policy scarcely seems to need discussion. During 1907 and 1908 Mr. A. C. Veatch was sent as a special commissioner to study the mining laws of the Australian States and New Zealand; his report to the Department of the Interior is perfectly accessible and ought to be enlightening to many minds now wrapped in the mists of preconception and prejudice. It is interesting to note in passing that coal mines are now in successful operation upon leased territory in the Mesa Verde National Forest. The really useful public servant should not be too jealous of instant and universal public approval. W. H. Seward was not afraid of the phrase 'Seward's folly,' and Mr. Fisher can afford to be fearless in the performance of public duty.

The Scope of the Bureau of Mines

It is proposed, at the forthcoming session of Congress, to amend the organic act creating the Bureau of Mines, and the local sections of the Mining and Metallurgical Society of America have been requested to make suggestions to the chairman of the House Committee on Mines and Mining. This is noteworthy in many ways. It is a recognition of the position and influence of the Society that is gratifying, and, following the recent pronouncement of the Council "We are unable to recommend, however, that any section shall have the right to make public its conclusions upon any matter under any circumstances," it constitutes an adequate refutation of the wisdom and advisability of any such policy. In this instance effective action precluded the possibility of securing the consideration of the Society as a whole, and this is likely to be the case in every subsequent instance. Finally, it is not too early to give the Bureau of Mines wider scope for its activities. Effective and useful as the work of the Bureau has been in fuel-testing, mine-rescue work, and the prevention of accidents in mines, it has, beyond its extension of mine-rescue work, been able to do but little as yet for the metal miner. Many professional men, especially the geologists, have deprecated the possible invasion by the Bureau of the field of the Geological Survey, with a possible useless duplication of labor. But the proper fields of work of the Bureau and the Survey are genetically distinct; the one is kinetic, the other potential, the Survey deals with deposits, the Bureau with their exploitation and use. The study of each involves the consideration of the other, but co-operation in important matters is possible and in small affairs unnecessary, just as an individual doses himself with quinine for a cold, but calls in a physician for serious ailments. In these days of 'trust-busting' it seems a bit inconsistent to eliminate all possibility of a little healthy competition between the Survey and the Bureau. But some suggestions for possible extensions of the work of the Bureau bear the stamp of futility, the most notable of these being the proposal that a testing laboratory for the gratuitous testing of ore and other products be established. Such a laboratory would be inundated with work, of which the larger part would be perfectly useless, and the remainder could be equally well performed under private auspices. Assay certificates from the Bureau of Mines would prove a godsend to the 'wild-cat' promotor, and, incidentally, many worthy citizens would find their livelihood interfered with. Analytical and testing work has, in most places, now been reduced to a base-level of cost. Prospectors of the right sort would be the first to resent an attempt to place them upon a charitable basis; the old timer always paid his own way, whether he was able to go far or not.

We would urge, in conclusion, the unwisdom of imposing unnecessary restrictions upon the work of the Bureau. In business it is clearly recognized that the best way to get action that is prompt, effective, and well directed, is to secure a man whose judgment, ability, integrity, and loyalty can be relied upon, and give him a free hand. Since we now have at the head of the Survey and the Bureau of Mines men of this character it cannot be doubted that the best policy to be pursued is one of freedom from hampering restrictions.

Characteristics of Chinese Labor

By Thomas T. Read

Much has been written regarding the characteristics of the Chinese, both by those who are amply qualified to express opinions of value and those who are not. It is not surprising, then, to find an extraordinary diversity of opinion upon Chinese topics, the opinions of qualified observers differing from each other almost as widely as from those of the casual tourist. There are many reasons for this state of affairs, the most potent being the striking topographic, climatic, and racial differences between different parts of China. It must be remembered that the centre of dispersion of the Chinese people is northwest of the area they now occupy, so that the southeastern border constitutes a true frontier. Along the frontier are found groups that differ markedly from the main mass of Chinese. The Cantonese, to mention but one of these, speak a language differing from that of four-fifths of the population of China to about the same degree that Dutch differs from English, while temperamentally they exhibit the same degree of contrast as between Italians and Germans. Since almost all the Chinese in the United States, excepting officials and students, are Cantonese, this must be kept in mind in attempting to generalize from the characteristics of Chinese laborers in the United States. This discussion pertains to the average Chinese, more especially in the north; essentially the same type of men as those imported into South Africa by the Transvaal Chamber of Mines. I will attempt to discuss their characters in logical order, beginning with physical characteristics that are least disputed. Easily the first of these is resistance to bad living conditions, acquired through centuries of existence under the strict application of the Darwinian principle of the survival of the fittest. Overcrowding, underfeeding, and generally unhygienic living conditions have no terrors for the Chinese workman, because he has always been accustomed to them. They are similarly resistant to the diseases common to China; smallpox is ubiquitous and is nowhere dreaded; the resistance to septic infection is very high, and Chinese patients often show marvelous recuperative power. In winter, when the temperature was below zero, my ricksha men have run with me until they were dripping with sweat, on stopping would bundle themselves in a few ragged pieces of clothing, and, contrary to all reasonable expectation, did not die of pneumonia, but seemed to flourish. It should be said, however, that there is a good deal of tuberculosis, to which the Chinese seem no more resistant than Europeans.

Endurance is a quality which cannot be estimated so exactly, because of its relativity. A well-fed man naturally has more endurance than one who is underfed, especially one who has habitually been underfed. Attention should be called here to the fallacious reasoning in the apocryphal story of the railroad contractor, who, wishing to hasten his work, conceived the scheme of taking away the rice from his coolies and feeding them upon beefsteak, with surprisingly gratifying results. Such a procedure is as irrational as the feeding of a cow upon bones in the hope of converting her into a watchdog. Men whose digestive systems are hereditarily adjusted to a vegetable diet cannot be instantaneously altered to a diet of animal food any more than a locomotive can be changed from coal to oil burning without a readjustment of its mechanism. Increased results from Chinese workmen are to be secured by providing them with sufficient quantities of well cooked food of the kind to which they are accustomed, and not by making radical changes according to preconceptions. There are many features of the Chinese social system that at first sight appear adventitious, but which, upon careful examination, are found to be essential. An egocentric attitude of mind is not conducive to obtaining insight into Oriental problems.

Strength is equally incapable of discussion upon an exact basis, both because of the absence of exact data and because individual Chinese vary greatly in this regard. The general, and probably correct, impression is that the average Chinese is smaller than the average American. As a matter of personal opinion, I believe that Chinese brought up under good living conditions would at least equal in strength Americans of equal weight, and would perhaps surpass them. It must be remembered that this discussion applies only to laboring men, the literary and merchant classes, both by training and natural inclination, avoid all forms of physical exercise and are notably deficient in strength and endurance.

Skill can be adequately discussed by prefacing my remarks by the observation that Chinese are singularly lacking in imagination, having a literalness of mind that frequently astonishes the foreigner. This, coupled with great manual dexterity, produces results that are in some cases astonishingly good and in others disappointing, according to the amount of influence which each of these factors has in the outcome.

The mental characteristics of the Chinese are even more remarkable than their physical attributes, but considerations of space prevent too prolix a discussion. Perhaps the most striking is their hereditary cheerfulness, amounting almost to a national optimism, which is perhaps exemplified in the expression for 'tomorrow', *ming-t'ien*, 'bright day.' This is coupled with patience, which is a characteristic of all Orientals. Most astonishing to the foreigner is a habit of mind that considers everything from a viewpoint different from his own. This, with Chinese self-sufficiency and European intolerance and impatience, is usually at the bottom of all friction between the two races. Out of the relations between the Greeks and Romans and their African slaves has been derived the Caucasian sentiment that all colored races are inferior. The Chinese, by centuries of contact with immediately adjacent inferior races, have developed a similar attitude of mind toward all foreigners, and were not prepared for the advent of the Caucasian. But mutual acquaintance leads to mutual respect.

Chinese workmen are teachable, providing they have no previous knowledge of the subject taught. They are lacking in initiative, and are not good leaders or 'bosses.' They do much better work under foreign than under native supervision. Some years since, H. C. Hoover expressed a somewhat unfavorable opinion of Chinese labor, but it must be remembered that the Chinese Engineering & Mining Company took over an organization which had been for some years under native control. Under such circumstances the work of alteration of methods would be much more difficult than the creation of an entirely new staff of employees. The Chinese tendency to stick to known methods is most exasperating to foreigners, as is their tendency to try to reduce everything, even an indefinite proposal, to a definite systematic basis. This latter has its advantages, but they are not to the fore in pioneering work. As regards mechanical ability, the British officials of the Imperial Railways of North China have expressed to me the opinion that the Chinese mechanics are at least equal in efficiency to the average British mechanic, and I have corroborated this from other sources and by personal observation. And I have never seen any workmen who excelled the Chinese in the making of molds for castings.

Training and supervision of native labor is all-important, but the remarks by Wickham Quinian in regard to the Filipino, given on another page, are of such universal applicability that a further discussion here is unnecessary. The 'proof of the pudding' is the labor cost per unit of output. Where able-bodied, industrious laborers can be obtained for an average daily wage of 8 cents, and skilled labor, such as locomotive engineers, receives as a maximum $45 per month, it would be natural to expect low labor costs per unit. This is evidenced by the fact that the Han-Yeh-P'ing Iron & Coal Co., mining about 1000 tons per day of iron ore from open-cuts, almost entirely by hand labor (see pp. 453-454, *Mining and Scientific Press*, October 7), is able to mine it at a total cost of about 30c. per ton, as compared to a stripping cost of approximately 34c. per cubic yard at such mines as the Nevada Consolidated and Utah Copper.

The Alaskan Situation

By Walter L. Fisher

*The injurious effects of the joint or common ownership of coalfields and railroads have already been seen, and the attempt to remedy by drastic legislation the evils which the withdrawal of the coalfields of Alaska should prevent from recurring there is now being made. * * * This does not mean that Alaskan coal should not be developed and developed at once. It means merely that it should be developed properly as well as promptly.

Alaskan coal is of great value, but its extent and character have been much exaggerated. * * * The better known of Alaskan fields is the Bering river field, which is near Controller bay, and in which the Cunningham claims were located. * * * The Matanuska field is larger and may prove to be the most important. Both of these fields contain anthracite and high-grade bituminous coals. The question is how they shall be opened so as to promote development and protect the public interests. * * * Alaskan coal can be opened so as to enable a larger or smaller number of individuals or groups of individuals to make money out of their development. * * *

I personally visited the Bering field and examined some of its coal seams and coal mines. It is situated along the foot of the Chugach mountains, in the region a little south of Prince William Sound and some 1200 miles from Seattle. The field covers an area of fifty square miles or 32,000 acres, lying approximately twenty-five miles from the coast at Controller bay, with an immense glacier, known as the Bering glacier, on the east, from which the Bering river runs and empties into Controller bay. This field was discovered in 1896 and practically all of it appears to have been covered by claims entered under the law of 1904. The country is exceedingly rough and broken and the rocks are faulted and folded to an extraordinary degree, so that the larger portion of the coal beds in this field are crushed, leaving what otherwise would have been the highest grade of bituminous coal so that much of it cannot be mined as lump coal, but only in a finely crushed condition. There is, however, some coal in the field which doubtless can be mined as lump, but how much there is of this coal remains a question of considerable doubt. This doubt is further intensified by the fact that in the crushing process the coal seams have become pinched so that beds of considerable thickness at one point become thin or even pinched out within a short distance, making it difficult to determine what will be the condition of the beds at any given point beyond the explored area. * * * Aside from its crushed condition, much of the coal itself is of excellent quality, possessing high calorific power. The crushed condition does not interfere with its coking quality if otherwise good. Although it can be briquetted, or with the use of specially constructed furnaces it can be burned successfully in its present form, its physical condition will undoubtedly interfere with its immediate commercial value. * * *

As the Controller bay region is only twenty to thirty miles distant from the coalfields, there have naturally been numerous investigations to determine the possibility of constructing harbor facilities there. I am told that it was carefully investigated on behalf of the Copper River railroad by engineers of high standing and was discarded as impracticable. The attempt, however, was made under the advice of engineers of this road to construct a harbor at Katalla, which is outside of the range of islands to the westward of Controller bay, where there is deep water immediately off shore and where a pier or breakwater was constructed at considerable expense in the vain attempt to protect shipping from the force of the winds and waves of an open roadstead. A storm promptly demolished these works and led to their removal to Cordova.

Obviously, if modern dockage is provided at Cordova for copper ore and other heavy freight, it can be made to provide for coal with less additional expense than if separate facilities should be constructed on Controller bay. Nevertheless, several other railroad enterprises have been projected at Controller bay, but apparently all have become inactive except that in which R. S. Ryan and his associates are interested. It was the persistence of Mr. Ryan which led to elimination of the shore of Controller bay from the Chugach National Forest, and he has made three scrip entries on the shore, which are still pending before the Department of the Interior. Following the law, these entries each have a frontage of 160 rods, leaving 80-rod intervals between them, which the law provides shall be kept free from entry. On one of these 80-rod strips a railroad terminal has been located, but this entry appears to be without any warrant of law and is based wholly upon the theory that a railroad terminal location does not constitute an entry within meaning of the act. It seems to have been made merely to exclude others and upon the chance that the statute may be open to the construction mentioned. I do not believe that it is even intended to be seriously pushed. At all events, all the rest of the shore, except as stated, remains free from entry, thus disposing effectively of the claim that a railroad monopoly has acquired the frontage of Controller bay. Whatever may be the merits or demerits of this harbor, it has not passed out of the control of the Government. * * *

My visit to Alaska has led me to take a far greater interest in the future of the Matanuska coalfield, which is larger in extent, having an area of seventy-four square miles or 47,360 acres, better in coal, better in physical condition, and freer from the complications of private claims than is true at Bering river. Against these advantages must be set off its greater distance from the sea, but this very distance connects it more intimately with the real problem of Alaskan development—that of adequate transportation from tidewater to the Yukon. What Alaska needs more than all else is a trunk line railroad from the ocean to the great interior valleys of the Yukon and the Tanana, opening up the country so that its development may be possible.

The Matanuska coalfield lies north of Prince William Sound and from 150 to 200 miles from Seward, on Resurrection bay. It is known to contain extensive beds of coal of the same or slightly superior quality to that of Bering river, and in better physical condition both as to the coal itself and as to the obstacles to profitable mining. The country is not so broken, faults and pinching are less in evidence, and the crushing process appears to have gone on to a much less extent. A much smaller part of this field has been entered by private claimants, and most of these appear to be clearly illegal on account of dummy entries and other violations of the law, for which indictments are now pending. A railroad to develop this field and to open up the great interior valleys has been started from Seward, which has by far the best harbor and the best townsite in Alaska which I saw or of which I have been able to obtain any knowledge. The town of Seward lies at the head of Resurrection bay, which is a magnificent and extensive harbor, landlocked and free from ice, and already selected by the Government as a naval coaling station, and where the smelter operations may be one of the future industries.

The only criticism of the harbor of which I have heard is that the water is so deep that docks and fixed moorings will be necessary for perfect safety, but as this is also true of the harbor of Seattle, which has been regarded as one of the most magnificent in the world, it seems to be a fault which closely approaches a virtue. The railroad from Seward—the so-called Alaskan Central or Alaskan Northern—at present extends only seventy-odd miles to a point on Turnagin Arm, where it stopped for lack of funds and for various other reasons, among which the withdrawal of the coalfields from entry is particularly emphasized. * * * While a part of its construction does not seem wisely adapted to the transportation of coal or other heavy freight, I believe this road should be continued on to the coalfields and beyond them to the interior, and that if private interests do not care to undertake the task the Government should.

If a plan for construction at the joint risk and joint

---

*An address delivered at the American Mining Congress, Chicago, October 27.

profit of the private investor and of the public along the lines of the Chicago Traction ordinances could be put into successful operation, this might reconcile the conflicting views of public policy as to the Government ownership of railroads, especially if the Government's share of any future profits should be commuted into an equivalent reduction of the rates or should be directly expended in furnishing to Alaska the other means of transportation of which it is and will continue to be so much in need. After such careful consideration, however, as I have been able to give to the matter, I believe that the uncertainty of immediate financial return will prevent the adoption of this plan and that the imperative need of immediate transportation development calls for the construction of at least one main trunk line from tidewater to the Yukon, which can better be constructed from Resurrection bay through the Matanuska coalfields than in any other way. * * *

The Matanuska coal should be brought to Seward for the use of our naval coaling station, and a mine for that purpose can well be opened by the Government on the Matanuska, where it can be made to serve as an example for private mining, where it can furnish information and serve as a check upon the profits of the lessees under Government leases. * * *

If we may assume that some of the coal claims which have been entered in Alaska, in either the Matanuska or the Bering fields have complied with the law and should be allowed, the suggestions I have made will enable us to compare in practical operation the development of coal under private ownership, under Government leasehold, and under the direct operation of the Government itself. We shall have an important railroad under private ownership, with governmental regulation, to compare with one under public ownership, and these two railroads will operate in separate fields where they will not directly conflict, but where each may serve as a check upon the other, and the advocates of both methods will doubtless come to appreciate more fully and more fairly both the difficulties and the advantages of the railroad as a governmental agent.

It remains only to consider more in detail the methods by which the coalfields should be opened. Those suggested have been the sale of lands in fee, their development under lease from the Government, and their operation by the Government itself. I believe that the time has passed when the Government should convey an unrestricted title to its coal lands. * * * But direct government operation, including the mining and selling of coal, involves such deep and far reaching changes, both of policy and of administration, that there is no present likelihood of its adoption. * * *

I believe the leasing system avoids the controversies and difficulties of both extremes of public and private ownership. It has been adopted with conspicuous success in the great mining communities of Australia and New Zealand. It is now the established law of the Yukon Territory lying in Canada just across the border line from Alaska. It is the system under which much of the privately owned coal land of the United States is in fact today being developed. Under it we can insert as matters of contract and as conditions to which the lessee voluntarily consents those regulations and requirements which promote the public interest, the enforcement of some of which by mandatory law might be unconstitutional. By making the terms of our leases liberal we can make them even more attractive to capital than if we adopt the policy of sale of the fee. * * *

In the southern Appalachian coalfields, just south of the Pocahontas region, it is estimated that 75% of the area is mined on a lease basis; in the Hocking Valley region of Ohio, 75%; in Iowa, more than 70%; in Arkansas, 60%; and in Oklahoma nearly all of the coal land is operated on a lease basis. In our principal coal mining States, the census figures for 1909 show that out of a total of 6,900,000 acres of coal lands under operation, more than 2,000,000 acres, or 30% of the whole, was in 1909 operated under a system of private leases. It is therefore substantially correct to say that, whether we like it or not, the choice is not as to whether we shall mine our coal on the leasehold system, but whether we shall mine it under leases from private owners or directly from the Government of the United States.

That the consumer has everything to gain under the governmental leasehold must be apparent, for the Government can make its royalties as little as it chooses and it has no invested capital and no unearned increment on which to pay returns. Opposition is to be expected only from those who wish to secure our coal lands for stock jobbing or speculative purposes. * * *

Expedients could be adopted in the effort to enforce development by requiring the purchaser to mine a certain amount of coal or to expend a certain amount of money in developing the land under pain of forfeiting his title to the Government, but this, after all, is only a crude and awkward device for securing what can be far more effectively secured by means of lease. * * *

In our own country, in the States of Wyoming and Colorado, when it was proposed that these States should lease their coal lands instead of selling them outright, it was argued that nobody would take out the leases. But experience has shown otherwise. In Colorado, in 1900, in addition to the large acreage of coal lands held in private ownership, nearly 6000 acres of State coal lands were operated under lease, and in 1910 nearly 20,000 acres of the State coal lands were being operated under such lease, with a royalty charge of 10c. per ton. In Wyoming today more than 3,000,000 acres of State lands of all kinds are being operated under 5700 leases. * * *

Some of the bills which have recently been introduced in Congress provide that the Interstate Commerce Commission shall regulate the prices at which the coal mined under these leases is sold not only by the miner, but by the middleman and the retailer to the consumer. Important as is the question of protecting the consumer, it seems unwise that price regulation by the Government should be insisted upon as a necessary feature of a coal leasing law for Alaska. Obviously such regulation must extend to the retailer if it is to do anything but enable the middlemen to make the profit denied to the miner. Regulation of this sort would be a new departure in either State or Federal administration. It raises fundamental questions of public policy about which differences exist that are as yet uncompromising. It would doubtless prevent any early action by Congress. Certainly if enacted in the form presented in these bills, * * * it would prove a serious, if not prohibitive, barrier to the development of a new country and a new and uncertain market.

The prime requisites of a leasing system are that only sufficient coal lands should be leased to meet the existing market and encourage its development; that the quantity leased to any one lessee should be limited to the amount that can be profitably mined as a unit and yet be large enough to attract investors; that the lessee shall pay his royalty as he mines his coal; that this shall annually amount to a fixed minimum which will make it unprofitable for him to hold the land without production; that he shall mine his coal without unnecessary waste and with due regard to the health and safety of his employees; that he shall not engage directly or indirectly in any combinations, agreements, or understandings to control the price of coal, and that the revenues derived by the Government shall not be used as a source of Federal revenue or as a substitute for taxation, but shall be devoted to the development of the State or Territory in which the coal is mined.

In his address, October 28, President W. H. Taft said:

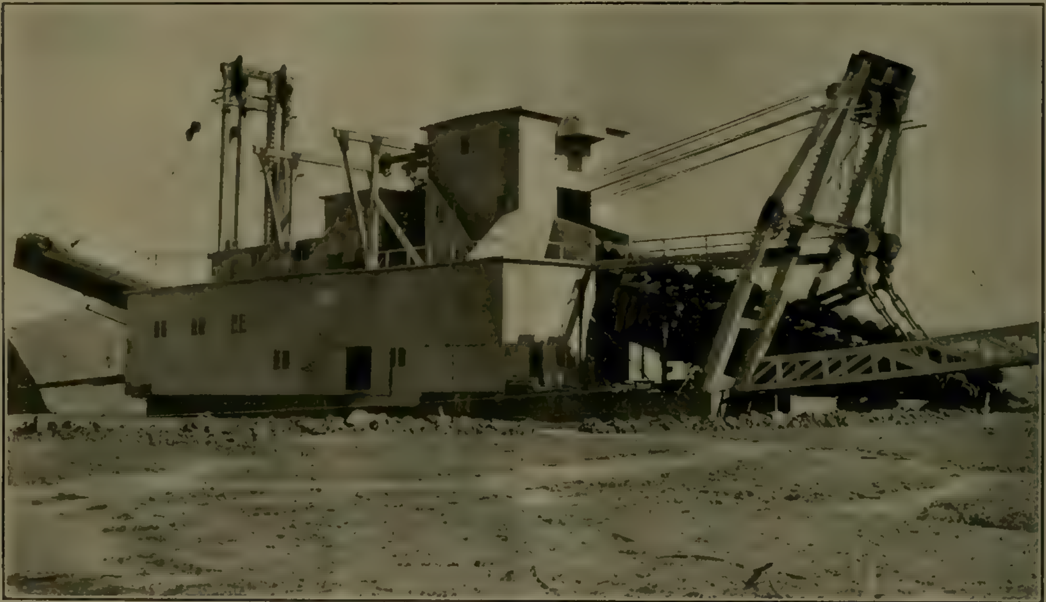
You heard last night a very interesting address from the Secretary of the Interior as to mining and the general subject of Alaska. I read the address last night, and I only want to say that I enjoyed the reading and approved it. He said in advance that he had published the address with my consent, after a general discussion with me, and now I want to make the confirmation complete. If the Secretary of the Interior will straighten out Alaskan matters and eliminate rodomontade and muckraking, and everything else that has interfered with the progress of Alaska, and put her on smooth seas and lead her on to only reasonable development, he will earn my undying gratitude, as well as my rejoicing as a citizen of the United States.

Dredging at Ruby, Montana

By Floyd Bushnell

One of the largest dredges in the world is being operated by the Conrey Placer Mining Co. at Ruby, Madison county, Montana, 80 miles southeast of Butte. This boat was built by the Marion Steam Shovel Co. at an approximate cost of $270,000. It is 150 ft. long and 60 ft. wide. The Conrey Placer Mining Co., which has its headquarters at Boston, was organized in 1898, when it took over the holdings of the German Bar Mining Co., formed two years previously.

The company controls about 1000 acres, and has an exceptionally good field for dredging. The distance to bedrock is from 12 to 60 ft. In places the gravel is cemented, making it difficult to dig. Occasionally boulders are dug up, but little delay is occasioned from this source. A monster boulder, five feet through, was lifted out of the pond by chaining it to the bucket ladder.



CONREY DREDGE No. 4, RUBY, MONTANA.

Until a few years ago steam was used exclusively as a motive power, but it was so expensive that it was decided to try electricity. Accordingly an electric line was built from the plant of the Madison River Power Co., a distance of 25 miles. An electric dredge, known as No. 3, was constructed, and it proved such a successful venture that it was planned to do away with steam as a motive power. Subsequent results have proved that a large saving has been effected by the use of electricity. Dredges No. 1, 2, and 3 are equipped with Westinghouse machinery, while No. 4 and the sub-station are supplied with General Electric machinery. At the present time the company is operating four electric boats, which move on an average 600,000 cu. yd. per month, but they could handle 20% more if pushed. It takes 300 hp. each to operate dredges No. 1, 2, and 3, and 1035 hp. for No. 4.

Dredges No. 1 and 2 are of the California type, with belt-conveyor stacker, the machinery being quite different from that of No. 3. The new dredges are of the close-connected bucket type, and dump 16 buckets per minute. No. 1 has 7½-cu. ft. buckets, and those on No. 2 are 9 cu. ft. No. 1 dredge is 96 ft., and No. 2 is 106 ft. long. They have 44-ft. beam and 9-ft. hull each; they dig approximately 37 ft. below the surface. These two boats are floated in ponds 125 by 200 ft., while No. 3 requires a pond 200 by 210 ft. The cost of the first three dredges was about $384,000.

During the summer it was decided to remodel No. 3 dredge, so that its efficiency might be increased. The old ladder, which was 100 ft. long, has been replaced by one 15 ft. longer. It will now dig to a depth of 53 ft., 10 ft. deeper than the old one. To care for the extra weight of the ladder, two triangular pontoons have been constructed and will be placed under the front end of the boat at either side. The chain consists of 92 nine-cubic foot buckets. This is the first extensive repair work on the dredge during the past five years.

Dredge No. 4, the largest of its kind in the world, was put in operation the past summer. The actual time of construction was seven months, practically no work being done during the winter months. The company experienced much difficulty in transferring the machinery of this mammoth dredge from the end of the railroad line at Alder to the operating ground at Ruby, a distance of two miles. A traction engine was used and some of the larger pieces were dragged much of the distance. The hull is 150 ft. long with a 50-ft. beam and a 5-ft. overhang; it is 13 ft. deep. There are 659,000 bd. ft. of lumber in hull and housing. The ladder is 116 ft. long and will dig 53 ft. deep; the upper tumbler is 31 ft. above water. The bucket-ladder consists of 80 close-connected buckets, each of which has a capacity of 16 cu. ft. The hoods and bottoms are cast in one piece.

The bucket pins are 7 in. diameter and each bucket weighs 4200 lb. The revolving screen is 50 ft. long and 9 ft. 9 in. diameter. The stacker is 130 ft. long, carrying a conveying belt 48 in. wide. The boat has two steel spuds 80 ft. long, weighing 45 tons each. To operate this boat requires a pond 250 by 300 ft. This dredge is equipped with Worthington centrifugal pumps as follows: One 16-in. low pressure, one 16-in. high pressure, one 6-in. bilge pump, and one 10-in. sand pump. The boat complete weighs 2200 tons. The rubber stacker-belt is enclosed in canvas housing, heated by means of steam-pipes, making it possible to run in winter, but in severe weather the dredge is shut down.

The company recently built a substantial sub-station, into which the power comes at 46,000 volts; it is transformed down to 2200 volts and taken to the dredges. There are automatic switches and meters for each dredge, so that it is possible to take care of each boat without interrupting the others. In this way it can be told how much power each boat is using. A private telephone system has been installed, connecting all the dredges and homes of the dredgemasters and chief employees. Since the electrification of the plant a considerable saving has been effected in labor. The steam dredges required 11 men each in 24 hours, while under the present system 7 men care for a dredge. Charles Kammerer has been manager for the Conrey Placer Mining Co. for the past 3½ years and has been in the employ of the company for the past 12 years.

The company has a complete retort and melting house, the walls, partitions, floor, and roof being entirely of cement and absolutely fireproof. The building is 24 by 36 ft., and contains a retort and melting room, a panning room, where the clean-up is handled and cleaned ready for retorting; a condensing room, where condenser pipes lead from the retort to carry off the fumes that might otherwise escape into the main building; and a concrete vault equipped with one of the latest improved doors and locks. In the retort-room are two Allis-Chalmers retort furnaces in which the amalgam from the dredges is retorted, and two melting furnaces in which the retort is melted and run into bars of bullion.

BUCKET LADDER, DREDGE No. 4.

The complete machine and blacksmith-shop is unusually well equipped. The shop is operated by a 50-hp. electric motor and employs eight mechanics. In this shop the company repairs and does all the finishing required on the dredges. In connection with the shop is a large storeroom, where are kept duplicate parts of all machinery used on the dredges, so that a breakdown can be quickly repaired. This machine-shop is a large factor in the successful operation of the dredges, which are run practically 90% of the time. All lost time is accounted for either in making repairs or in moving ahead. Eighty-five men are on the pay-roll of the company, and altogether several hundred persons are dependent upon the operation of the dredges for a livelihood. Ruby, a town of 250 persons, was built entirely as a result of the operations of this company.

The deposit now being worked contains 600 acres of proved dredging ground. Like many other alluvial deposits, it is generally fan-shaped, with apex at the mouth of the gulch. Its age (probably late Pleistocene), and the boulders and gold, in their subangularity and irregular bedding, denote a time of deposition much later than that of the California dredging fields. Other features indicate that it may be contemporaneous with those of Colorado. The surface has a slope to the west of about 1%, while the bedrock slopes slightly more to the west, thus as the work progresses in a westerly direction the depth increases until a maximum of 60 ft. is reached 2½ miles from the mouth of Alder gulch. The gravel, though not indurated in the ordinary sense, is tenacious and compact, due to the existence of clay distributed irregularly through it, particularly near bedrock. Here a greater amount of clay and a heavier pressure have combined to give a tenacity difficult to overcome; (1) in excavating with the buckets, (2) in discharging from the buckets, (3) in screening from the trommels, and (4) in sluicing.

The bedrock is an extremely tenacious clay, and varies in color from light cream to dark brown. It seems to owe its origin to deposition from slow moving or still water. It resembles the Oroville bottom, though it is more tenacious and sticky. It is generally smooth with but gentle undulations. There is no particular concentration of gold on or near it, nor does the gold penetrate into it. These features, together with the circumstance that when any considerable volume of it is excavated by a single bucket it must be pried or dug out (for it will not discharge), make it not only unnecessary but undesirable to more than skim it slightly. The gold averages from 800 to 840 fine. Its coarseness varies, about 40 to 60% passing 60 mesh and 15 to 38% passing 100 mesh. Much of the gold is subangular and coarse in comparison with that from the California dredging fields. It resembles the gold from Alder gulch, showing the same relation as is observed elsewhere between gold of debouchments and that of the creeks above them. I am indebted to officers of the Conrey Placer Mining Co. for information used in compiling this article, and take this occasion to thank them.

A large number of the shares of the Conrey company is owned by Harvard University; Gordon McKay, of New York, who was one of the principal shareholders, having recently bequeathed his holdings to that institution. For the past three years the company has used the bonus system in dealing with its employees. The first bonus amounted to $5000, the second $2500, and the third $3500. These amounts, divided among 65 men, are paid about Christmas time and are keenly appreciated by the employees.

Contact Deposits

By James F. Kemp

[*]In the truly remarkable progress which has been achieved in the study of ores during the past ten or fifteen years, the subject of 'contact deposits' has played a prominent part. Though long unappreciated at their true significance and regarded as merely subjects for interesting petrographic investigation, they are now recognized as one of the most important sources of copper and iron. The Southwest and Mexico possess wellnigh innumerable occurrences, and they do not fail in the Northwest, in British Columbia, and along the coastal districts of Alaska. Outside of North America they are not lacking, and it is always to be remembered that to the keen observational and interpretative powers of the Norwegian geologists is due practically their first recognition.[1] In the presentation of this subject, it will be my endeavor to first sketch briefly the types of contact zones which were early established by the petrographers, and then to summarize the theoretical views which were reached concerning them. The development of further views from later observations may next be outlined, leading naturally to the combination of petrography and economic geology in the latest investigations. There are some very interesting lines of attack which this particular problem has opened—lines which are fraught with much significance in relation to the large subject of the magmatic waters, and their influence.

By contact metamorphism is generally understood the processes of change which are set in action by an intrusive mass of molten rock and which work out their effects upon its walls. Recrystallization is started and new combinations of minerals form new and characteristic rocks. The effects are at a maximum next the intrusive, and die away in concentric zones or aureoles or halos as the observer goes outward. The intrusive mass itself does not escape, but almost always shows along its borders the compact textures due to quick chill.

The extent or frequency of the metamorphism varies with different kinds of intrusives. It would obviously be more frequently seen and more extensively developed with magmas rich in dissolved vapors. The crystallization of these molten masses to the several anhydrous silicates, which make up the final rock, drives out the dissolved vapors as magmatic waters and provides thus a powerful agent of alteration along the borders. Acidic magmas or those high in silica are the rocks generally believed to be most richly provided with these so-called mineralizers and as a matter of observation they are the ones around which are found the largest zones. Basic rocks are less likely to produce the changes, yet instances are known in which zones are associated with them. It is an interesting coincidence that cold, basic rocks have been found by Rollin Chamberlin to be the richest in gases.[2] Apparently the gases remain in the minerals of these rocks to a greater degree than in the acidic types. Again, large bodies of deep-seated rocks are more efficient agents than are small bodies, or than surface flows which only rest upon some underlying support and which soon lose their vapors into the atmosphere. On the whole, granites, with their close relatives, syenites, diorites, and the intermediate types, the monzonites and granodiorites, produce the largest zones.

Turning to the wall rocks, it is found that the zones are especially developed in two varieties of sediments: the richly aluminous, embracing the shales and slates; and the richly calcareous, the limestones. Sandstones are stubborn and unyielding subjects; while rocks already metamorphosed, such as gneisses and mica schists, have practically reached the limit of change. One therefore looks to the shales and slates on the one hand, and the limestones on the other, for the principal zones. The latter are more abundantly associated with ores than are the former.

The aluminous rocks develop a series of aluminous silicates of which andalusite, $Al_2O_3.SiO_2$, is most characteristic, so that the contact rock is often called an andalusite hornfels. Either with the eye alone or with the microscope the finger-like prisms of this mineral can be detected and often the white and black crosses of the variety chiastolite appear in the dark hornfels. The home of chiastolite is in these zones. Other rather less characteristic minerals are sillimanite, $Al_2O_3.SiO_2$, staurolite, $(AlO)_4(AlOH)Fe(SiO_4)_2$, biotite, amphiboles of several varieties, and quartz. The zonal rock is often dense, black, and flintlike, suggestive of its name, hornfels or hornstone. Sometimes, at a distance from the intrusive in the outer zones, are found the rude beginnings of crystals of andalusite or staurolite or even only the segregation of pigments in spots, which have received the name of spotted schists or the local German terms of *fruchtschiefer* and *garbenschiefer*, names scarcely capable of significant rendering into English. In North America the best known zone of this type is at Mt. Willard in the White mountains. It was described in 1881 by George W. Hawes and will continue to furnish instructive exhibits to others while geology endures.[3] The zones are not lacking in the West, however, and of them more is certain to be heard from time to time. They do not fail in Europe, in the old mining districts of the Hartz and the Erzgebirge, but are seldom, if ever, productive of useful minerals.

The limestone zones are of greater interest. They yield a larger variety of minerals than do the aluminous rocks, and aside from their connection with ores, they are on the whole the most prolific of all mineral localities. The commonest minerals characteristic of them are lime-silicates of one sort or another, but these simple compounds can be varied by additions of other bases until a long series of minerals results. The most characteristic of all is garnet, once thought to be exclusively the variety grossularite, $3CaO.Al_2O_3.3SiO_2$, but now known to be more largely andradite, $3CaO.Fe_2O_3.3SiO_2$. With this in almost as great amount is diopside, $CaO.SiO_2.MgO.SiO_2$, while in less abundance or frequency we find wollastonite, $CaO.SiO_2$, epidote, $2CaO.AlO.OH.Al_2O_3.3SiO_2$, vesuvianite, $5CaO.MgO.Al_2O_3.AlO.OH.5SiO_2$, scapolite, $3CaO.2Al_2O_3.6SiO_2$ (variable), quartz, SiO_2, magnetite, Fe_3O_4, specular hematite, Fe_2O_3, and many more of lesser importance. As a group they are often distinctively called 'the lime-silicates.' The rocks range from coarsely crystalline to very dense, fine-grained varieties, whose minerals can only be determined by the microscope.

The so-called garnet zones may be developed in strata next to intrusives, or they may spread outward along favorable beds for moderate distances,[4] or they may be developed around masses of limestone which become torn off from the walls by the advancing tide of molten rock and which may be then corroded and worked over into the new minerals. Such blocks may be later cast out from the crater of a volcano and, as at Vesuvius, furnish a long list of minerals. If the included blocks are very large (some even attain the size of small hills) they may be surrounded by large enough zones to yield orebodies.

The commonest ore which is found associated with contact zones on limestone yields iron. The iron minerals magnetite and hematite seldom fail in any zone, but they are often in masses of commercial size and purity. Practically all the iron ores of the Cordilleran region, except those at Hartville, Wyoming, are of this character. The best known are in the Iron Springs district of southwestern Utah, recently described by Leith and Harder,[5] but there are many more in the desert regions of southern California. The iron ores seem to have been brought from the eruptive rock during its cooling stages by magmatic waters and to have replaced the bordering limestone. They may also have been deposited in veins in crevices in the eruptive itself where they look like black dikes and by some observers are regarded as such.[6] Even if a deposit of any other metal had never been seen in the contact zones, the development of these iron ores would have shown this particular one to be a prolific emission from the cooling magmas.

---

[*] From 'Types of Ore Deposits,' by H. F. Bain, E. R. Buckley, S. F. Emmons, W. H. Emmons, F. H. Hatch, O. H. Hershey, J. D. Irving, J. F. Kemp, A. C. Lane, C. K. Leith, R. A. F. Penrose, Jr., T. A. Rickard, and C. H. Smyth, Jr. Published by the *Mining and Scientific Press*. Ready about December 15.

[1] This, and succeeding numbers, refer to citations given in the original text.

Next after iron ores are those of copper. They are, as first precipitated, chiefly chalcopyrite or bornite in association with still larger amounts of pyrite. Alteration and secondary enrichment yield the usual train of higher sulphides and of oxidized products, but chalcopyrite and bornite seem to be the first members in the series. They and their attendant pyrite may fill crevices in the older iron ores, and may be mingled with the garnets and other silicates, but all three sulphides seem to follow the silicates and iron oxides in periods of deposition. The copper ores of first deposition are usually lean and of low grade. Secondary enrichment is needed in many cases to bring this first product up to a minable richness. Chrysocolla is, on the whole, the commonest product, but oxides and carbonates also appear, especially if there is calcite in the immediate vicinity. Instances are known, although not so common, in which the original sulphides are rich enough to smelt in the crude state. Copper ores from garnet zones are not well adapted to concentration. The high specific gravity of the gangue militates against a satisfactory separation. In the crude state, moreover, and unrelieved by secondary enrichment, these ores are usually too silicious for self-fluxing smelting, and when the copper is present as chrysocolla there is much danger of loss in the slag. The low tenor in copper makes the addition of barren material undesirable if it can be avoided. On the other hand, injurious ingredients are rare. Arsenic and antimony are unusual. A favorable feature is the characteristic but small percentage of gold, with which may occur 1 to 2 oz. of silver. The ores are irregular and fortuitous in their distribution in the zones. They may come in without warning, and they fade out in the same way.

There are one or two variations from the type of copper ores as just described. Whereas the usual experience is to find the copper disseminated in the zones of silicates, or in the associated bodies of magnetite, or in large individual masses of sulphides, at the mines of the Mazapil Copper Co., Aranzazu near Concepcion del Oro, Zacatecas, it favors large veins of coarse calcite that cut across the garnet zone outwardly from the intrusive into the limestone.[7] At the Cumberland-Ely mines in the Robinson district of Nevada, the lime silicates, while not entirely lacking, are much less abundant than in the cases cited. The zone is largely rusty chalcedonic and opaline silica within which, and well below the present surface, a great orebody has been discovered. This rusty silicious rock admirably illustrates those outcrops described in the West as 'blowouts.' In this instance silica seems to have replaced the limestone rather than to have combined with the lime.[8] The copper mines at Bisbee, Arizona, have also presented a case of contact zones that differs from the usual. Next the intrusive rock and over a width of about 200 ft. there has been developed a zone consisting of quartz and calcite, while outside of this and ranging over a width of approximately 1000 ft. the limestone is in large degree changed to a finely crystalline mass consisting of tremolite, pyroxene, garnet, vesuvianite, quartz, chlorite, and a few minor minerals. In this zone are situated the larger number of the orebodies, but some occur still farther out in the almost unaltered limestone. F. L. Ransome, who has described the area, is inclined to attribute an importance influence in the ore formation to one or two great faults which cross the contact zones. The metamorphic changes seem less thorough in the Bisbee case than in many others, more calcite remaining in the end-product.[9] In the Velardeña district of Durango, Mexico, J. E. Spurr and G. H. Garrey have worked out an unusually complicated case in which in addition to the zones from limestone, a diorite has also developed along the borders into an aggregate of garnet and pyroxene. The common experience is to find the effects upon the eruptive itself limited to fine crystallization from chill.

A different type of orebody from all of these is supplied by the copper deposit at White Knob, Idaho. The garnet zones here appear as pipes or trunks within the mass of the eruptive, although not far from the contact. Ten different pipes outcrop, but they come together within 700 ft., so that at the bottom levels there are but three or four surviving. The gangue of the ores is garnet, diopside, and calcite, as is usual, and in this case it appears as if calcareous hot waters had risen from below through the still heated eruptive and had produced the silicates.[10]

Iron and copper ores are, however, not the only ones found along the zones. Lead and zinc minerals were early noted in the Kristiania region and more rarely those carrying bismuth, antimony, and arsenic.[11] In Washington Camp, Arizona, copper has thus far been chiefly sought, but W. O. Crosby states that zincblende is more abundant[12] and galena is also well represented. In fact the complicated mixture of these several varieties has been one of the difficulties in the utilization of the ores of this particular locality. Zincblende is a rather common associate of copper ores in the zones. The mineralogy of the famous and unique orebody at Franklin Furnace, New Jersey, is much more closely akin to the contact zones than to any other known type, although it seems not to be in immediate association with a possible eruptive that could have produced it in this way. Gold associated with wollastonite has been recorded from the Santa Fe mine, Chiapas, Mexico.[13] It also occurs in the same relation, as I have observed, at the Cane Spring mine, in western Utah. Even platinum has been detected by L. Hundeshagen, with the same mineral in a contact zone, in Sumatra.[14] W. H. Weed has emphasized the sylvanite with less abundant native gold at Bannack, Montana.[15] The same observer found bismuth telluride (tetradymite) with bismuth sulphide (bismuthinite) at the Dolcoath mine in the Elkhorn district, Montana,[16] and also gold-bearing arsenopyrite at the Nickel Plate mine on the Similkameen river, British Columbia.[17]

It is evident from this review that the contact zones present a fairly wide range of metals, nevertheless it is true that copper has been the one of leading value hitherto. Iron, although somewhat utilized, remains chiefly for the future. Lead and zinc are known, but are not yet obtained in quantity from well established types. Gold has been found in several cases by itself, while it and a little silver are rather common associates of copper. Platinum has one recorded instance.

The contact zones, as stated at the outset, furnish particularly significant objects of study. The older idea of the formation of the silicates involved the re-crystallization of material in the orignal limestones without the addition of anything new. It was believed that where the zones are now found there was once a silicious, aluminous stratum, whose silica, alumina, and lime combined to yield grossularite or epidote; whose silica and lime gave wollastonite, or with magnesia, diopside, or with this and alumina, vesuvianite. Carbonic acid and water were evicted. Where small percentages of iron oxides appear in the silicates they were referred to the limonite or siderite molecules originally in the limestone. If a great eruptive dike or other form of intrusive cut across a series of limestone beds, and developed in some places the silicates, and elsewhere merely marbles, the inference was naturally drawn that in the former case the limestone was earthy or impure and the latter but slightly contaminated.[18] In the interesting exposure at Washington Camp, Arizona, where there is some scattered chert in the limestone, rims of wollastonite were found by W. O. Crosby surrounding the still remaining inner masses of chert.[19]

Along these lines a very interesting and important study was carried out by Joseph W. Barrell[20] both for aluminous and calcareous zones. Assuming the raw materials to be in the limestones with which the metamorphosing agents must work, and that they were calcite, magnesite, kaolinite, and limonite, it was possible to calculate the amounts of these which would be needed for the production of grossularite, diopside, or other silicates, and the amount of carbonic acid and water which would be driven off. By dividing percentage compositions by specific gravities, ratios were obtained, proportionate to the volumes of the several minerals, before and after. The number of volumes lost in the change could be computed and it was found to be impressively large. Thus in the production of grossularite, from calcite, kaolinite, and quartz, the lost carbonic acid and water and the increased specific gravity of the garnet involved 46.9% of cavities in the new rock, unless compression were to diminish them. Diopside necessitated 42.4% and wollastonite 32.8%. In the aluminous rocks andalusite would leave 27%. In Barrell's view porous belts of rock were thus afforded in which circulating solutions might later deposit ores. The hypothesis may, however, be tested in several ways: (1) What was the composition of the original limestone and did it contain the necessary ingredients for grossularite and the other lime-silicates? (2) Is the garnet of the zones actually grossularite? (3) Do the zones show the cavities that these calculations call for? (4) Do the silicates first form, producing cavities which are later filled by the ores?

The composition of the original limestone can be determined at least approximately by samples taken from the same bed or stratum at a distance from the eruptive. This has been done at San Jose, Tamaulipas, Mexico,[21] and at Morenci, Arizona.[22] In the first case there was less than 1% ferric iron and alumina and only 4 to 5% silica. The samples were taken in the endeavor to get a fair indication of the general composition. It certainly would not seem possible to conclude that grossularite in wide zones could have resulted solely from a limestone of this composition. At Morenci, the Modoc limestone, which is the one chiefly converted into garnet, is shown by Lindgren's analyses to have less than 2% silica and less than 3% alumina and ferric oxide. George Smith in the Chillagoe district of Queensland records limestones of 1.25% silica and less, and of less than 1% alumina and iron oxides.[23] So far as these analyses are significant, it is again obviously unreasonable to expect zones of almost solid garnet, several hundred feet wide[24] to be formed by the re-crystallization of an original of anything like this composition.

Hydraulic limestones are indeed known and are extensively used for natural rock cement. They range from 25 to 37% silica, 7 to 17 alumina, and 1 to 5 ferric oxide, and so far as chemical composition is involved they might yield grossularite, diopside, and other silicates, but they are rather unusual rocks as limestones run, and their presence should be demonstrated in each particular case rather than assumed. The presumption and such evidence as is available in the way of analyses are against their presence.

In answer to the second query as to whether the garnet is really grossularite, the lime-alumina variety, there is even more significant evidence. In the San Jose case, the garnet proved on analysis to be over 60% andradite, the lime-iron variety. In the Morenci instance it proved to be almost pure andradite.[25] The garnet from Washington Camp has also been found on analysis to be predominantly andradite. While it is greatly to be desired that these analyses may be multiplied as time goes on, and that samples may come from many additional localities,[26] enough evidence is at hand to justify the conclusion that the unquestioned assumption of grossularite is unwarranted. Now, while it might be possible with apparent justice to reason about a supposed limestone high in alumina, it is a very different matter to assume one high in iron. Richly ferruginous limestones are almost unknown, and thus a strong presumption is raised against the re-crystallization of material solely derived from the limestone. In the White Knob case where the pipes of garnet rock were in the eruptive, two analyses showed respectively 69.26 and 47.82% grossularite, with 21.13 and 44.16 andradite. These results, while higher in the aluminous variety, were by no means lacking in the ferruginous, even when the wall-rock of the pipes ran 16 alumina and only 1.59% of both oxides of iron.

The third query as to whether as abundant cavities are found in the garnet zone as the calculations call for is to be answered by observation. The theoretical abundance could hardly be expected to be actually reached. No zone is pure garnet. Diopside, and epidote or other lime silicates whose production involves fewer cavities, are seldom if ever lacking. There is also more or less calcite, and there may be not inappreciable quantities of quartz. Yet after critical observation of several zones with this point in mind, I have felt that the cavities were not as abundant as would be rightly expected on the re-crystallization hypothesis, but that there are often belts several feet wide of very dense rock. Vugs and cavities do occur, but they are too few in numbers. If cases like the zone of the Cumberland-Ely mine in Nevada, be examined, zones are found that are so largely pure silica that the re-crystallization hypothesis can hardly apply. To a less but still appreciable degree it is difficult to use it for diopside, a mineral higher in silica than the garnets, or for wollastonite, which is likewise more silicious. From only a few per cent in silica, ten or less, can hardly be believed to have been produced a rock that is either almost pure silica or composed of silicates fairly high in this acid radical.

In several localities the succession of the minerals in the zones has been worked out both by means of microscopic slides and by study of the hand-specimens. In the San Jose case the order seemed to be the following, the only question being the time relations of the lime silicates and the magnetite: (1) diopside and garnet; (2) magnetite; (3) pyrite and chalcopyrite. At Morenci, Lindgren records the simultaneous crystallization of the lime-silicates and magnetite together with some of the sulphides, whereas other sulphides are clearly later and cut the earlier minerals in veinlets. At the White Horse Pass mines in the Yukon, O. Stutzer determined the following order: (1) pyroxene, and rarely magnetite; (2) magnetite; (3) garnet with a few metallic sulphides; (4) amphibole and the greater part of the sulphides; (5) calcite.[27] Stutzer cites in this same paper the observations of O. E. Leroy upon the deposits of Texada Island in which the pyroxene precedes the sulphides, but the relations of the latter to the garnet are not mentioned. In some detailed observations upon garnet zones at Velardeña, Mexico, J. E. Spurr and G. H. Garrey note a number of successions in all of which the formation of garnet or some other lime-silicate comes first and the entrance of the metallic minerals follows.

These cases fall in line well with Barrell's view that the metallic minerals might be deposited in a porous rock, made so by the re-crystallization of the limestone, but it is fair to say that they might also leave the eruptive at a somewhat later stage than the silica, iron, and alumina and continue the replacement of the limestone or might fill any cavities that had resulted when silica and its associates evicted carbon dioxide. Magnetite and hematite occur in such great bodies and are so clearly replacers of limestone that the introduction of iron oxide from the intrusive mass seems established beyond question.

Not every observer has been inclined to view the garnet zones as contact effects. Some have thought them intrusive masses themselves. George Smith, in describing the Chillagoe, Queensland, occurrence mentions garnet rock 200 ft. wide enclosed in granite, and regards this, as well as occurrences along the border of the granite and limestone, as intrusive in nature. Most geologists, however, favor the hypothesis of production of the garnet by contact metamorphism and would be inclined to interpret the mass wholly enclosed in granite as a great limestone fragment altered by the eruptive or as formed in some such pneumatolitic manner as is necessary to assume for the White Knob, Idaho, case. Not a few observers in the field have doubtless speculated on the possible absorption or in-fusion of limestone along the border of the intrusive rock, and have wondered if at the time of its entrance the intrusive mass were not sufficiently superheated to make this possible. There is, however, as a rule, a pretty sharp line of demarcation between eruptive and sediment, and there is also a gradual passage of garnet or other lime-silicate rock into limestone. Scattered garnets and pyroxenes gradually fade out into barren wall rock. Some rather well grounded objections to garnets from fusion have been found in artificial experiments. Thus if garnet of the grossularite type be artificially melted and the crucible allowed to cool slowly, not garnet, but a mass of anorthite, melilite, and pyroxene results. E. T. Allen and W. P. White have made some interesting demonstrations of the melting point and conditions of possible existence of wollastonite, one of the commonest contact minerals.[*] They find that at normal pressures wollastonite cannot exist above 1180° C. At higher temperatures pseudo-wollastonite results, a mineral of a different crystal system and one not known in nature. While it is possible that higher pressures may make differences, yet the fusing point of acidic eruptives is usually well above 1200° C. and the intrusive masses may have been much higher. Wollastonite does form at normal pressures as low as 860° C. There is some reason thus to think it not a product of crystallization from fusion, but the result of the still highly heated after-effects. The banded arrangement of the lime-silicates, moreover, the vugs with their coats of crystals, the veinlets of sulphides, of quartz and of calcite itself, all argue against fusion and in favor of pneumatolitic processes.

Thus it has come to pass that almost all the recent students of these contact phenomena have interpreted them as due to the emission of water-gas and other highly heated vapors, which, with continued fall in temperature, in time give rise to highly heated waters. Where to draw the line between the two physical forms is scarcely known. The further speculation seems justified, that if the issuing gases and waters do not encounter limestones or aluminous rocks and are not relieved of their dissolved elements near the intrusive mass, they may rise as hot-springs and with diminishing pressure and temperature fill veins in the upper rocks. The abundant silica of the contact zones and its predominant occurrence as a gangue in the fissure veins are two things that may be of complementary significance.

The German Potash Syndicate

By Talbot J. Albert

*The Potash Syndicate furnishes an excellent illustration of what constitutes a German syndicate and distinguishes it from an American trust. Only by the study of a concrete example can the difference be clearly understood. There are two significant and material distinctions. The first is that the Potash Syndicate and most of the other syndicates have, as such, no capital or shares of stock which are dealt in on the stock exchange, as is the case with an American trust. The second distinction is that a syndicate is a combination for a limited period of time, usually five years, while the life of a trust is indefinite.

The units composing the Potash Syndicate and most mining syndicates in Germany are companies of two kinds, namely: those whose capital is divided into shares called *kuxe;* and those whose shares are of the ordinary, joint-stock variety with limited liability. The shares of the joint-stock companies are non-assessable, but on the other hand *kuxe* are shares that are assessable at any time and are of unlimited liability. These *kuxe* and shares of the individual concerns are dealt in on the exchanges of the large cities of Germany.

Each company that is a member of a German syndicate has its representative on the board of management of the trust, and this board fixes the quota of production allowed each mine and generally administers the affairs of the entire combination under its constitution and by-laws *(statuten)*. The constitution and by-laws must be signed by each concern entering the syndicate and the provisions therein contained strictly observed under penalties enforceable in courts of law. The mutual obligations of the syndicate toward its constituent members and the duties of the members toward the syndicate are thus protected by law, making it a legal combination.

The weak point in this form of organization is the dissension that often arises as to the quotas allowed the different members. Each company wants as large an allotment as it can get and there is disappointment if it is not received. For this reason upon the expiration of the life of a syndicate there is always uncertainty as to whether it will be renewed, owing to the competition among the various constituent firms. The object of a syndicate is not monopoly, but the prevention of disastrous competition. It is an agreement among producers of an article to prevent overproduction, so that supply will conform to demand and reasonable profits may be obtained. There is no outcry in Germany against syndicates; they are generally looked upon as organizations advantageous to well-regulated trade.

The German Potash Syndicate, a combination of seventy-six companies, is now practically in complete control of the potash mining interests of Germany. The chief competing mines were Einigkeit and Sollstedt, in the Brunswick consular district, and Aschersleben, in the Magdeburg district. Some time ago Einigkeit, which is controlled by American capital and has been connected with the so-called South Trust in the United States, came to an understanding with and was admitted into the syndicate. Now an agreement has been reached between the Potash Syndicate and those interested in the Sollstedt mine, by which Sollstedt is allowed the free delivery of salts under the contracts with its American customers until the end of 1911. Out of the profits a payment will be made to the International Agricultural Corporation of New York, which owns the shares, or *kuxe*, of the Sollstedt mine, and the balance will be paid by the syndicate, which will co-operate with Sollstedt in settling lawsuits threatened or instituted against the mine. At the end of 1911 the sales of salts exceeding the quota allowed the mine will cease, and it will become a member of the syndicate. In carrying out the agreement between Sollstedt and the syndicate it is provided that the International Agricultural Corporation shall enjoy all the benefits granted to the other large American importers of potash under the agreement made at the Hamburg conference in May last. The entire American business of Sollstedt with the International Agricultural Corporation will become centralized in the syndicate.

The agreement between Aschersleben and the syndicate provides as basis for union that the mine shall receive $357,000 from its American customers ($178,500 from the so-called North Trust anad $178,500 from the International). In lieu of a preference quota Aschersleben demands from $142,800 to $190,400. The justice of this claim has not yet been admitted by the syndicate, but, with counter demands and offsets, it is being considered, and there seems little doubt but that a final agreement will be reached and the mine become a member of the syndicate. In consequence of the increase in the quota of the Volkenroda potash works and the allotment granted the Weitmannshall works, a new apportionment of the quotas of all the companies in the syndicate has been made, which went into effect October 1, 1911. The potash production of the syndicate is divided into 1000 parts. The largest share (25.14) is apportioned to Leopoldshall mine and the smallest (3.44) to the potash works at Halle. The allotments to the three mines that have hitherto been outside the syndicate and which made independent contracts for the delivery of salts to American customers, are: Aschersleben, 20.68; Sollstedt, 15.24; and Einigkeit, 14.54.

With the absorption of these three mines into the syndicate all competition ceases. As Germany is the only country in the world in which potash mines are being profitably worked, and as the mines are controlled by one combination and their production and sales of potash regulated by the special law recently passed by the Reichstag, the German Potash Syndicate may be fitly termed a legally reinforced trust. The unworked potash field in the Duchy of Brunswick, Province of Hanover, and elsewhere in Germany is immense, but under the law no new mine or combination of mines can become competitors of the syndicate.

*Abstract from *Daily Consular and Trade Reports.*

The Seneca Mining District, California

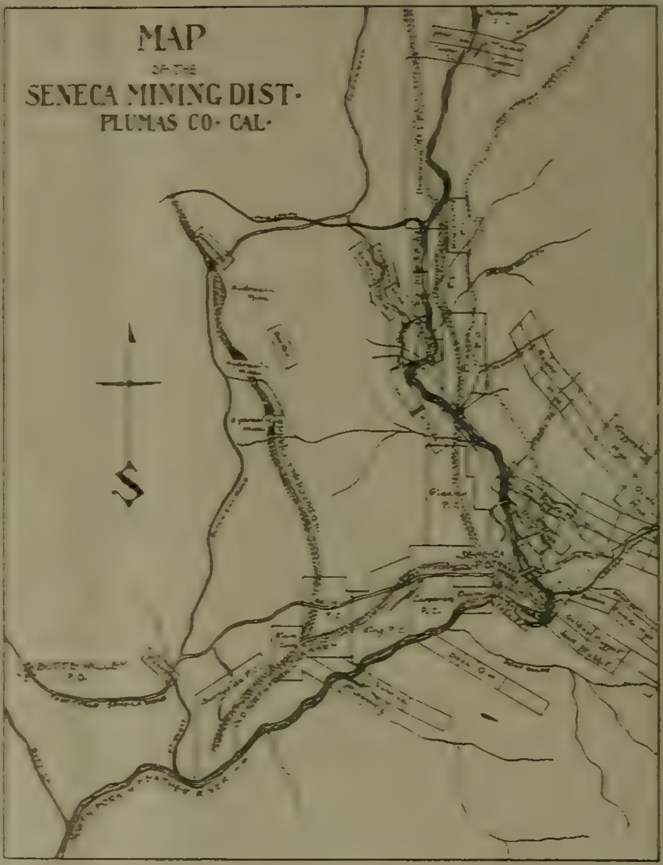
By F. L. Wilson

The Seneca mining district lies near Lassen Peak, in the northern part of Plumas county, and near the head of the north fork of the Feather river. The district extends from the mouth of Butt creek on the south to the dam-site of the Great Western Power Co. on the north, with an approximate area of 28 square miles. Seneca, the principal town, is reached by 45 miles of staging from Keddie, the nearest station on the Western Pacific railway. This distance will shortly be reduced to about 25 miles through the building of a new county road which branches from the old road near the town of Greenville and runs to the dam-site of the Great Western Power Co. and from there down the east side of the north fork to Seneca. The road between Greenville and the dam-site is nearing completion, and work may be started on the Seneca road.

The topography of the district is immature, as it is elsewhere in the uplifted portions of the Sierra Nevada. The north fork, cutting through the tilted sedimentary rocks and the successive lava flows, has a deep canyon. Between the Savercool and Dominion mines the walls are exceedingly steep. The river has a steep gradient, with an average drop of about 150 ft. to the mile. Terraces extend along the river, marking the course of the old channel, which was covered up by several successive flows of lava that extended nearly 20 miles down the river. The old channel of Dutch Hill is about 1000 ft. above the north fork and has been eroded, exposing gravel which has been hydraulicked to a considerable extent. Nearly a million dollars has been extracted from these hydraulic mines. The auriferous gravels are described by Diller as being of Neocene age, and the lava flow, that covered the channel before the region was uplifted, as basalt of the same age.

There are two old channels of the north fork, but the second one is not worked, although it contains gold, while the lower one has been worked for years. The river cuts it in two places and below these points there are rich placer workings. At the Dominion mine the top of the oldest channel is about 30 ft. above the river, and the other channel is about 200 ft. higher. The second channel is from 6 to 10 ft. thick, while the lower one is 15 to 40 ft. thick. Just above the Panama quartz claim the upper channel is about 40 ft. above the present one. The present river flows over a hard, compact slaty-schistose rock composed of greenish grains and called locally 'greenstone.' This belt is about 1200 ft. thick and has the usual strike of the district, N. 50° W. The old channel at the Dominion mine has cut through softer rock composed of slates and shales (see accompanying sketch), and at the Pliocene mine it crosses the greenstone and follows down the east side through the Glacier ground. The flows of lava extended down the north fork after the river had cut through the older lavas and auriferous slates, forming flats or terraces, and the gravel can be seen at numerous points along the terraces, just below the basalt. There is still a considerable portion of the channel that has not been prospected, and will in time be worked with profit.

Among the mines that have been worked are the Sunnyside, said to have produced $500,000; the Kelly, $8[illegible],000; the King, $40,000; the [illegible], $45,000; the Glacier, $30,000, and the Pliocene, about $25,000. At the Sunnyside mine, work is now being carried on in a new drift and gold is being washed out of the gravel of the old channel at a profit. Some work is being done on the Kelly mine and the Glacier mine. At the Dominion mine active prospecting is being carried on. A siphon has been installed to unwater a winze and found to work satisfactorily. Hungarian riffles are now in use, and other means of saving the fine gold and black sand will shortly be installed. Two samples of the black sand from this channel have assayed $850 and $1200 in gold, respectively. The gold examined under the microscope is metallic, adhering to particles of sand. The lava flows in the district are of different periods and range from andesite and pyroxene andesite to distinct basalts. Placers in the present channel of the north fork were at one time of great importance in the district, and some of them are still being worked. The Deane placer is profitable at the present time.

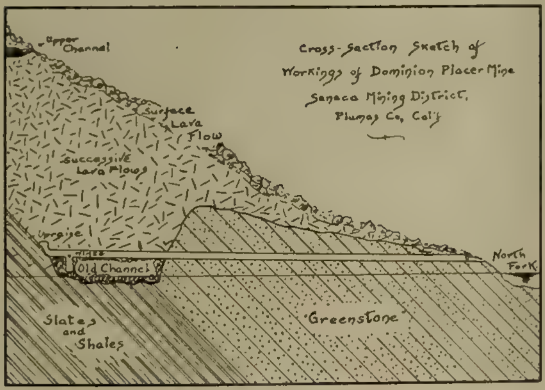


Next to the 'old channel' mining, quartz mining is playing an important part in the development of the district. Prospecting work is in progress at several of the quartz mines, particularly at the Del Monte, where another 100-ft. contract has recently been let. At the Dunn mine, the only profitable one so far in the district, a $6000 six-stamp mill is in active operation on the property. This mine and mill are owned and operated by the Seneca Mining & Milling Co. The discovery and development of this property is characteristic of the mines in this district. The White Lily (Dunn) quartz mine was discovered and located by the Dunn brothers in 1896. An arrastre was operated for one year, when a two-stamp mill, driven by a wooden overshot water-wheel, was installed and operated steadily for six years. In 1904 a 6-stamp mill was built and operated for 18 months, when it was destroyed by fire. In 1906 the present plant was built and has been in steady operation since. In 1907 the property was incorporated under the name of Seneca Mining & Milling Company.

The ore from the Dunn mine consists mostly of quartz, clay gouge matter, and some calcite, with fine flaky gold pyrite, and some galena. The ore assays 0.45 oz. in gold per ton, on the average. It is trammed from the mine in ¾-ton cars and dumped on 1½-in. grizzlies, the fine dropping into a 14 by 16-ft. bin, the oversize being shoveled into a 7 by 9-in. Blake crusher with discharge into the main bin. The fine ore is then fed by means of Challenge rotary feeders into the mortar boxes of the batteries. There are three of these batteries, of two 850-lb. stamps each, 100 drops per minute, and a drop of 6 in. The discharge of the pulp from the batteries is through 30-mesh angle punched metal screens to 40 by 90-in. plates. At present no attempt is made to save the tailing, but the management plans to install suitable concentrators soon. Arrangements have also been made for two additional batteries of five stamps each, and a hoisting and pumping plant for the mine, to be ready for operation about the first of the year. The mill is operated by water-power, the water being obtained from the north fork and brought to the mill through a flume 18 by 48 in. a distance of 1100 ft., and giving a vertical drop of 24 ft. The water from the flume passes through a 24-in. iron pipe into an 18-in. Leffel turbine, which generates about 20 hp., sufficient to operate the mill and other machinery. A 10-in. Victor turbine is used at night to run a 250-volt Westinghouse generator, which furnishes the mill and Seneca with 100 sixteen candle-power lamps. The output of the mill is 15 tons per shift of 24 hours. The company employs 8 men in the mine, and 4 in the mill.

SIX-STAMP MILL, SENECA M. & M. CO.

A RELIC OF FORMER DAYS.



CHANNEL AT THE DOMINION MINE.

On the Savercool claims prospecting adits were driven on the veins showing on the surface, and the ore from these was treated in a small quartz mill situated a short distance above the mouth of Ohio creek. Later a main adit was driven below these, and a larger mill erected. This mill was operated for a short time and then shut down due to the pinching out of the supposedly large pay streak. Later development on the property has failed to find the rich vein. The mill today is a total wreck. At the Horseshoe mine another stamp-mill was erected and operated for some time, but today stands idle, a monument to Seneca's lively early days.

Another item of economic importance to the district is the water development that is now in progress. The Great Western Power Co. has already developed the low water flow of Butt creek by means of a flume and pipe from a dam site near the Butt Valley power-house to the mouth of Butt creek. This gives a net head of 865 ft. The low water flow will generate, with the present machinery, 800 kilowatts. At a later date a high dam will be erected at the head of the flume and the plant built to produce a minimum of 6000 kw. continuous output. The storage in Butt valley will exceed 180,000 acre-feet. This storage is, however, small in comparison with that which will be obtained at Big Meadows upon the completion of the multiple-arch dam now in construction above the McMillan copper claim on the north fork. This storage will exceed 1,150,000 acre-feet. The dam will be founded on basaltic rock and will have a height above its base of approximately 144 ft. and a crest length of 660 ft. In the immediate future this dam will be used to store flood waters for liberation during the summer for the use of the company's plant at Big Bend. The company plans, in a few years, to divert the entire flow from the dam through a line of tunnels and then through a penstock to a power-house on the north fork near the mouth of Clear creek. The vertical drop will be approximately 1200 ft., and the plant when completed will generate 184,000 kilowatts.

New Zealand State Coal Mine

The general manager's annual report on the New Zealand State coal mines was issued at the end of August, and it is stated, in the Sydney *Daily Telegraph*, that the net profits of the enterprise for the twelve months are £1051, or a little less than 1d. per ton on the total output. The demand for the coal was undiminished, far exceeding the supply, which last year consisted of 260,803 tons, a decrease of 20,827 tons from the previous year's total. The Seddonville mine produced 51,550 tons of marketable coal, and the Point Elizabeth mine 209,253 tons. Considerable difficulty is found in disposing of the large quantity of small coal remaining from the lump supplied to the railways. The gross earnings last year amounted to £128,239, made up as follows: Point Elizabeth colliery, £88,764; Seddonville colliery, £18,624; briquette works, £2259; Wellington depot, £8415; Christchurch depot, £6404; Wanganui depot, £2119; Dunedin depot, £1652. The men in all branches are reported to have worked energetically and well.

Cyanidation in Colorado

By Marshall D. Draper

*The decadence of the mining industry in Colorado is attributable, in the opinion of some engineers, to the exhaustion of the more accessible and probably richer deposits of the first few hundred feet in depth. On the other hand, the large amount of development work necessary to extract those orebodies has, in numerous instances at least, also developed and exposed considerable bodies of lower-grade ore which, for various causes, are not now being treated. Cripple Creek, on account of the application of the cyanide process to the treatment of ore, has been more fortunate than some of the other districts, and although concentration plants have partly solved the problem of cheaper treatment in other districts, yet freight and smelting charges on concentrate cannot be avoided. It has been stated by San Juan producers that it is impossible to make small mines, of a production of ten to thirty tons per day, profitable on ore averaging less than $20 per ton. In considering this statement, a large number of conditions must be taken into account, such as the transportation cost to some treatment plant, treatment costs, the width of the vein, character of the ore—whether it contains other metals than gold and silver—mining costs, and it is impossible to say without detailed and definite data covering these points whether the statement is correct or only partly correct.

It is a well known fact, however, that ore of a grade that will not pay in the San Juan will pay in other Colorado districts, or in other States, this, of course, being due altogether to the difference either in the method or cost of treatment. Assuming that we have the ore ready for shipment, how is it that the shipper is unable to get any returns (I speak now of the San Juan shipper) on ore of a grade of about $10 per ton or possibly a higher grade? The answer is, that freight and treatment charges absorb practically all the returns from the ore. The establishment of some central custom-milling plant would create a market for such grade ores, and while it is not my opinion that the net result would be the immediate opening up of a number of mines, yet it would undoubtedly enable the small operator to exist and in the long run would greatly assist in the development of the mining industry in general. Given a possible production of about 100 tons per day, there are few mines which would not be justified in the erection of individual milling plants, but the difficulty with the small shipper is to prove his mine meanwhile. Such central plant could be arranged without difficulty for the treatment of lead and copper ores, where the concentrate containing these metals could at once be taken from the jigs or tables, the tailing from the milling operation being cyanided. The San Juan has been quoted as merely one of several districts in the State where such installation might be beneficial.

Together with several associates, I made a large number of cyanide experiments on the ores of Gilpin county, about two years ago, the various tests and experiments covering a period of about one year. It was found that there was no particular difficulty in the cyanidation of the ores, and crude concentrate containing 2% copper and only 10 to 12% silica could be cyanided direct without undue cyanide consumption and with a high extraction. As a matter of fact, the average extraction after the proper conditions were ascertained was found, on a series of sixteen parallel tests, to be 87%. Another point of considerable interest was that the average extraction of several Gilpin county custom-milling plants was found to be good, considerably better than has generally been supposed, and, in brief, probably in excess of 70%. Notwithstanding this fact, the shipper seldom receives a net profit of more than 50% of the gross value of the ore, and the difference has been found to be due to the freight and smelting charges on the concentrate.

There is no doubt whatever in my mind that the establishment of a central milling plant in Gilpin county with a treatment charge of about $2 per ton, would result in unparalleled activity in this pioneer gold district. This plant would use the ordinary present methods of amalgamation, followed by concentration, but would differ in further cyaniding not only the tailing but the concentrate as well.

The present situation, speaking of Gilpin county as a whole, is that the shipper is unable to work at a profit if the grade of the ore is under $6 per ton. In many cases this statement is equally true as to a head value of $7 per ton. A treatment charge of $2 per ton would insure a 300-ton cyanide plant a handsome profit, and the shipper would get some net returns from an ore running as low as $3 per ton, although this figure would not allow for any mining cost. The ores of Clear Creek county come under this head also, though not to so great an extent. As far as any lead content is concerned, it may be said, as before, that in the operation of a plant of this kind it would be a simple matter to divert the lead concentrate at any point and ship direct.

The cost at the New Portland plant at Victor is said to be something less than $1.25 per ton, and the cost at the Independence plant about $1.23. Average costs on Gilpin county ores may be estimated at about $1.08. It is probable that average costs on San Juan ores would be somewhat higher, as freight on supplies is higher and general costs are somewhat greater. It is safe to say, however, on the scale outlined, that the cost on approximately a 300-ton plant would be not to exceed $1.50 per ton, and when the plant was in good running order it is probable that this cost would be considerably reduced.

From the milling standpoint it must be admitted that there is much to be desired in the development of economical methods in Colorado. I believe that more could be accomplished toward rejuvenating the mining industry by the establishment of modern mills at central points than by any other means at present known. How this condition could best be attained is hard to say, and is a matter that is hardly within the scope of this article. It may be of interest in this connection to note that a prominent company took up the matter of the establishment of a custom plant in Gilpin county, their engineers looked into the matter and stated that they reported favorably on the feasibility of the plan. In the absence of some energetic promoter, the scheme was allowed to be supplanted by other matters of a more pressing nature and nothing was done. Engineers, in the very nature of things, are seldom good promoters, even if their inclinations are that way, and as the originators of this particular project were all engineers, the matter at present is as dormant as the mining industry in some sections of the State.

In my opinion, as previously stated, the most promising field is in San Juan county and in Gilpin county. It may be that Ouray or possibly Telluride would also offer inducements, though this could only be ascertained by careful investigation. Alma and Breckenridge might also be favorable fields. I hardly think that the silver losses in concentration in the case of the silver districts, such as Aspen or Creede, would be great enough to warrant such an installation. A smaller plant situated at some central point in Gunnison county might be a benefit. Such a plant in Clear Creek county would very likely prove of great benefit to operators. Cripple Creek has two individual installations embodying modern practice, but I am not aware that there is any custom plant embodying the latest practice, so that this might be a promising field for a 200 to 500-ton plant.

Shipping men in London are forming a steamship line to run from Sydney, New South Wales, to Valparaiso, Chile, with a view to utilizing the railway over the Andes between Chile and Argentina for a shorter route between Australia and England than is now possible. It is calculated that mails can be carried over this route in four days less than the time taken by way of San Francisco and New York. It is interesting to note that mails from Berlin to Peking sent over the Trans-siberian railway are delivered in thirteen to fourteen days from the time of mailing.

*Abstract from the *Colorado School of Mines Magazine.*

The Outlook in Rhodesia

Johannesburg Correspondence

Accounts received from Rhodesia so far this year are not nearly so optimistic as was the case twelve months ago. Scarcity of employment and money are now spoken of, and a growing disinclination on the part of European shareholders to put up capital for mining ventures is noted. There has been a good deal of talk lately about the glowing prospects of the tin discoveries in Rhodesia, but Johannesburg, having transferred most of its talkers to Rhodesia, knows what reliance to place upon those who prefer talking to work, which unfortunately is the case with too many of those who have migrated from the Rand to Rhodesia. If talking does not make a mine, it will not be the fault of the would-be Australian tin experts with which the Transvaal has had so many sad experiences during the past ten years. Excellent museum specimens there will be no dearth of, as well as of talk and prospects, but this method of booming tin prospects inflicted such damage on tin mining in the Transvaal, about seven years ago, that the effects are still felt, and Rhodesian speculators would do well to take a lesson from Transvaal experience. Several of the best Australian and other tin talkers, who worked up the Sallies fiasco on the Rand, are now engaged doing the same in Rhodesia. Both tin and copper surface prospects here are decidedly delusive and deceiving, and until their existence in profitable quantities is proved by actual work, no amount of talk will turn a prospect into a mine.

PROSPECTING IN RHODESIA; TYPICAL VELDT.

Even when the gold possibilities of Rhodesia are considered impartially, one is struck by the plethora of prospects, and the dearth of established mines; for after fifteen years' work the dividend-paying company-owned mines can be counted on the fingers of one hand. Last year's gold output showed little better than others gone before, 40% coming from small producers, but this fixity of output is said to be due to more attention being paid to development. Despite this increased development, however, it is generally admitted that Rhodesian goldfields suffer more from a lack of development than anything else, and under ordinary circumstances this would be taken to indicate a lack of confidence. So far Rhodesia may be best described as a land of highly promising prospects, an Eldorado of the ancients, but unless the prospects are followed up by a bolder policy in the future than has been the case in the past, it will continue to be a country of prospects rather than of profitable mines. In a country like Rhodesia, where the ore often occurs in lenticular bodies as in Barberton, there is more speculative attraction and possibilities than on the Rand, and were the prospects followed up, every prize realized would entice the expenditure of more capital. Some of the properties are being worked with energy, but they are altogether out of proportion to the promising prospects; and for a good deal of the lack of capital, claim-holders are much to blame in asking for impossible terms. The general impression is that so long as Rhodesian properties are sought to be dealt with on unsuitable mining and financial conditions, so long will they probably continue to be in the hands of the small producer.

Australasia Mineral Production

The tables giving the mineral production of Queensland and the rest of the Commonwealth and New Zealand for last year, and for the ten years ended with 1910, disclose some features of interest. It is shown that the year's mineral output of the Commonwealth and New Zealand reached a total value of £28,036,864, which is £750,400 more than for the year 1909. New South Wales once more tops the list, with a value of £8,455,170, Western Australia being second with £7,056,450, New Zealand third with £3,791,133, and Queensland fourth with £3,710,222. It has to be noted that only in the case of New South Wales and Queensland are the returns for 1910, all the others being for 1909, but this fact probably does not alter the respective positions of the States. As a producer of gold, Western Australia continues to lead the other States and New Zealand by a long distance, Victoria coming second, New Zealand third, Queensland fourth, and New South Wales fifth. In silver production New South Wales again comes first, while New Zealand has displaced Queensland for second honor, the latter ranking third. Tasmania reports only the value of its silver-lead ores, and not of silver separately. In the output of copper Queensland continues to hold premier position, with a yield valued at £932,489, Tasmania again coming second with £608,038, and New South Wales third with £486,257. In tin, Tasmania is once more first, and Queensland second. New South Wales, of course, heads the list in coal production, second honor again being taken by New Zealand, with Queensland once more third. Looking at the figures relating to Queensland's output of minerals during the past ten years, it will be seen that, in spite of the large falling off in gold, the total annual mineral production increased during the decade from £3,124,574 to £3,710,222. In that period silver production expanded from £62,241 to £92,685 per annum; copper, £194,227 to £932,489; tin, from £93,723 to £243,271; coal, from £189,877 to £322,822; and other minerals from £32,742 to £244,000.—*Queensland Government Mining Journal.*

The Filipino as a Laborer

By Wickham Quinian

Will the Filipino work? Most assuredly. Is he a first-class laborer? To answer this question intelligently requires some explanation. I regard the great mass of the laboring element of the islands, from the standpoint of development, as children. They have never had an opportunity to develop qualities inherent in them, which go to make a first-class laborer. I say that these qualities are inherent in them, and I speak from ten years experience in handling native labor. The natives in the city of Manila who have had an opportunity to learn how to use their hands and heads are giving a good account of themselves. There has been a steady improvement in the quality of native labor since it was first used, ten years ago, until the present time. At no time have as satisfactory results been obtained from native labor as at present, and this may be unquestionably attributed to the fact that the natives who are now serving best on pile-drivers, derricks, in machine shops, and elsewhere, have been going to school, so to speak, for the past ten years. Therefore if you ask me: are Filipinos, speaking collectively, a first-class laboring element? my answer is emphatically, no. But, on the other hand, if you refer to that class of native labor which has been brought into contact since American occupation with Occidental methods and under American supervision, has been taught how to do things, then my answer is, most unequivocally, yes.

Every individual or corporation engaged in the development of any enterprise in these islands is necessarily dependent upon native labor to accomplish his or its task, and success or failure will depend largely upon the persons to whose task it fails to supervise the operation of the native labor. If by nature and temperament he is tactful, patient, in other words, a good schoolmaster, using the ruler when necessary, for he is dealing with children, he will succeed. You know, as someone has said, there are more balky drivers than balky horses.

The laborer in the provinces has not had the advantages of his city cousin. Nature has been lavish with these islands, and it is not to be expected that the provincial native who has an unlimited credit with Nature, a better bank than the Bank of England, should be looking for work when he has but to shake a few cocoanuts from the trees, levy an assessment on the banana trees in the hills back of his *casa*, or draw fish from the river to supply his needs. Why should he work? You or I under similar conditions would take life as easy as he does. But there are inherent in the provincial native the same qualities that have made the Manila native a first-class workman, and as time goes on the horizon of the provincial native will broaden, he too, coming in contact with Occidental methods and ideas, will develop a taste for the better things of life, for the gratification of which he will be glad to labor, as do the natives of Manila and other places in these islands who have had proper training.—*Far Eastern Review.*

The Platinum Market

St. Petersburg Correspondence

The rise of the platinum market at its chief centre, Ekaterinburg, in the Urals, has for some time been uninterrupted until the 83% metal reached the unprecedented price of 10* roubles 10 kopecks to 10 roubles 20 kopecks per zolotnik about a week ago. There had been for some days whispers of a weakening in the demand, but suddenly this, if it ever existed, was swept aside and it was creditably stated that although the official price was 10r. 20k. the buyers were willing to pay at the mines as much as 10r. 30k. per zolotnik.

But at last the weakness in demand has appeared and is having an effect on the market. The demand for platinum on the part of local speculators is what may be termed a stationary one, and it must be owned that the sellers are equally indifferent; and although the season for producing platinum will in a short time be closed by the frosts, as far as independent workers are concerned, which would result naturally in a reduced supply, there is all the same a tendency shown to lower prices. The latest official quotation on the Ekaterinburg metal exchange for 83% ore is 10r. 5k., or 5k. less than a week ago, while at the mines the price named is 10r. 20k., and a week previous to that it had been 10r. 30k. Confident authorities, however, on the spot contend that the reduction is not to be accounted for by the market having become overstocked with platinum; but rather because of the inability of foreign houses to invest in the metal as a result of the Turkish-Italian war, which has had the result, so they say, of reducing the share values of foreign-platinum concerns. That is why, says the report, the demand for platinum has somewhat decreased.

Cyaniding Tailing at Bodie

By An Occasional Correspondent

Wichman Bros., of Yerington, Nevada, are engaged in cyaniding some old tailing, sixteen miles below Bodie on Walker river. This tailing has been exposed for a number of years, having been carried down by floods from the Bodie mills.

The method followed is to plow the tailing for ½ to 1 ft. in depth, then disk and harrow, load into wagons, and haul to tanks. As much of roots, grass, and sticks were taken out as could be easily removed. A small amount of lime is added to counteract the acidity, and solution is run on and allowed to leach, no attempt at agitation being made. A saving of about 93% is claimed. The average content was about $3 per ton. A royalty of 50c. per ton is paid, or an average of about $900 per acre, and the operators report having made a little better than wages. The small profits are due to the shallowness of the deposit. This land before the removal of tailing would grow only a very poor quality of grass. Here is an instance of how the rancher 'gets back at' the miner, for if he collected damages from the mining company that allowed the tailing to run upon his land, then $900 per acre in royalties, and has his land in as good condition as before, he surely did not lose much. Of course, he did not necessarily collect damages.

From this point to Bodie cyaniding has been carried on over almost the entire river valley. Much of the tailing has been carried upon the land by irrigation.

Tuquerres, Colombia

By F. P. Gamba

This small town of 6000 inhabitants is one of the most important in the Department of Marino, being the centre for the neighboring mining districts. The construction of the town is very poor, but Tuquerres is improving greatly, principally by the rapid development of the mines. Situated at an altitude of 3000 metres (10,100 ft.), at the base of volcano Combal, it enjoys a very healthful climate, a little cold, but agreeable. The environment is the most picturesque that can be imagined, and the land is fertile.

The distance between Tuquerres and Barbacoas, the river port on the Patia river, is 31 leagues (93 mi.) which is covered in five days journey on muleback on one of the best roads in Colombia. It would be easy to transform this mule road into one for automobile freight, and doubtless it would be a first-rate business to get a concession for the construction of the automobile road between Barbacoas and Tuquerres.

The largest mining enterprise in the Department is the Gualcala Mines Co., near the city, owned by an American concern and managed by R. A. Linton. The very productive mines of La Concordia and El Socorro are also nearby, and most of the mines of the country are at no great distance. The trip from New York to this place can be made in twenty days. New York to Colon and Panama; Panama to Tumaco, Tumaco to Barbacoas by steamers on the river Patia, and Barbacoas to Tuquerres on muleback.

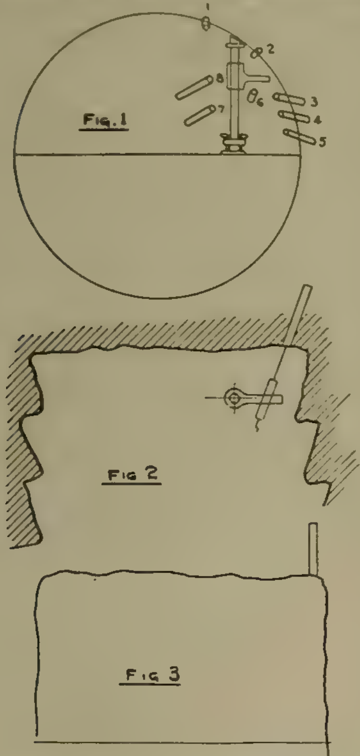
---

*1 rouble = 51.5c.; 1 kopeck = 0.01 rouble; 1 zolotnik = 4¼ gm.

Foreigners are well liked here, some Americans are doing well in business. John Bidlake, former United States Consul at Barranquilla, has rendered a positive service to the miners by opening a shop well provided with tools and dry goods. He is well esteemed here. Many businesses would be developed and pushed in this city. The population is white and Indian, very little mixed, the two races have kept themselves separate. The Indians are first rate workers and splendid miners when they are once taught. The wages vary as follows: peons, 20c., miners, 40c., and carpenters, 40c. The feeding costs 30c. per man. The local currency here is silver, at an exchange rate of 250 against gold.

Long Column Arms in Tunnels

In driving tunnel headings of oval or semicircular cross-section, ranging from 10 or 12 to 18 or 20 ft. wide on the floor, a customary method is to employ two columns, each carrying two drills. In order to complete the round and break the ground to the best advantage it is necessary either to move the columns or to set up a third column. A device for obviating this delay has been used recently with success in tunnels on the line of the New York City water-supply aqueduct. It consists merely of a column arm of unusual length, 30 or 36 in. This is set near the bottom of the column, and gives the drill a much wider range in placing the holes than the arm of ordinary length.



LONG COLUMN ARM IN TUNNEL-DRIVING.

With this long arm a tunnel wall or rib may be carried straight, instead of as a series of offsets, with the resulting roughness, which must be reduced by filling or trimming. In the sketch, Fig. 1, is shown a column with a short arm. It must be set far enough from the rib to permit the arm to swing between the rib and the column when the arm is placed for drilling the holes at the top of the tunnel.

Hole No. 1 is drilled with the arm on the left side of the column. The arm is then swung to the position shown in the cut, and holes No. 2, 6, 7, and 8 drilled. If this arm or a bottom arm of the same length is used for the lower rib holes, No. 3, 4, and 5 would be drilled as shown in Fig. 2, leaving an offset. The use of a long arm on this column allows holes No. 3, 4, and 5 to be drilled as shown in Fig. 3, and the difference in appearance of the rib when the two arms are used is shown by Fig. 2 and 3. These arms are, of course, made of extra strong material to withstand the strain placed on them when the drill is working at the outer end.—***Mine and Quarry.***

ALL INVESTIGATORS agree that the essential ingredients of portland cement are lime (CaO), silica (SiO_2), and alumina (Al_2O_3). The principal factor is the lime, and the more combined lime present in a cement the greater will be its strength. The lime limit is reached when there is more lime than will combine chemically with the silica and alumina. High lime cements usually set slowly but harden rapidly, and reach their maximum strength in a short time. When the raw materials are brought together in the kiln, some of the lime combines chemically with the silica, forming calcium silicate, and some of it combines with the alumina, forming calcium aluminate. These chemical combination must take place in definite proportions, a lack of combination making an unsound product, because of the free lime present. In slacking, lime expands, so that an excess of uncombined lime will cause the cement to expand, or 'blow', as it is technically termed, and crack. Next to the lime, the most important constituent is the silica. The true strength and hardening of a portland cement is due to calcium silicate. The silica should exist entirely in a combined state, and not as quartz sand, in which condition it does not combine with the lime, and is inert in the subsequent reactions. A portland cement, therefore, should tend toward a composition approximating the proportion: lime, 76.6%; silica, 26.4%, as lime and silica combine as tricalcic silicate ($3CaO,SiO_2$).—*Proc. Am. Soc. Civ. Eng.*

ALL THE FILAMENTS of water flowing side by side within a pipe must possess the same hydraulic energy. Energetic equilibrium within the pipe will always direct the flow of each particle in the direction of an equalization of energies, should any external influence upset the balance temporarily or locally. The filaments near the walls, however, are continually subject to such an external disturbing influence, in the form of the frictional resistance of the wall surfaces. Thereby they are constantly kept in a condition of deficit of velocity head. Thence a continuous fault in the energetic equilibrium results. As the sum of pressure head and velocity head for all filaments must be equal, those near the walls, possessing lesser velocity head, must possess greater pressure head. This, however, is hydrostatically impossible; yet, hydrostatically, it would have to occur, if the filaments were moving in straight parallel lines; therefore, the hydrostatic equilibrium becomes unstable, following the instability of the energetic equilibrium. The water, in order to regain its stability of equilibrium, is forced, by this unbalance of hydrostatic pressure, to abandon its original—or, at least, its hypothetical—straight-line parallelism, and to turn to the right or left in a helical path. Since the instability of equilibrium is indifferent as to right or left, in whichever direction it happens to be started it persists, because it finds therein stability of equilibrium.

IN Plumas county listings of quartz gold run from 627 to about 850 and the placer gold from 800 to 950. In Sierra county gold from quartz mines varies from 622 to 883; gold from the hydraulic mines at Port Wine (a Tertiary channel) is 948 in fineness. At Gibsonville similar deposits show a fineness of about 900. In Nevada county the quartz veins produce gold ranging from 645 to 890. The Tertiary gravels of the Harmony channel show the lowest grade of placer gold; it is 790 fine, but is derived from a small channel immediately crossing a number of rich veins so as to offer little chance of enrichment. In the main channel, at the Manzanita mine, at Nevada City, the fineness is 830. Gold from the deep channels of North Blomfield and Relief has a fineness of 906 and 935; at the Alpha hydraulic mine, 940 to 950; at American Hill and French Corral, all in main channels, 930 to 950.

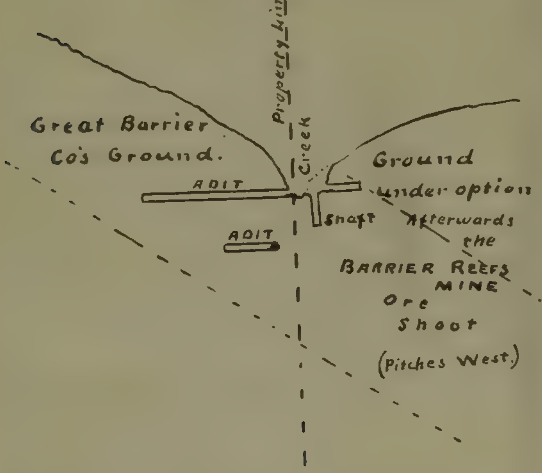
Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Surface Indications of Ore-Shoots in Depth

The Editor:

Sir—W. H. Storms' article and sketch which appeared in your issue of November 11, reminds me of a case in New Zealand, on which I had to advise, about fourteen years ago. A friend of mine had an option on some mining ground, and it was a matter of great importance to him as to whether or not the ore-shoot would cross the creek at depth. He had to make a quick decision, as a large cash payment was nearly due on his option. His end line was at the creek, and the Great Barrier company, on the east side of the creek, had nearly all of the ore-shoot at that time developed. That company had a 250-ft. adit driven east from the creek on the vein, and it was in good milling ore all the way. Sixty feet below this adit they had cross-cut the vein, by an adit, and they had driven a little way on the vein from the cross-cut. The ore there appeared to be as good or better than above. I was not privileged to sample the workings at that time. My client had only about forty feet of the ore-shoot on his ground, as it pinched out entirely at that distance from the creek. If the shoot pitched to the east, and did not cross the creek, the property he had under option would be almost valueless, as his small portion of the ore-shoot would soon be in the adjoining property.



The vein is an east and west fissure in andesite, and is from 2 to 3 ft. wide. The andesite then showing in the workings was yellowish-brown, soft, and much decomposed. The vein dipped to the south 60 to 70°. The ore had about an equal gold and silver content in a quartz gangue. The silver occurred as sulphides, black, ruby, and silver glance. Occasionally a little zincblende showed, and this always assayed high in gold. No free gold could be seen in any of the ore. My friend had sunk a 30-ft. inclined shaft, on the vein and near the creek. In the bottom of the shaft was about two feet of ore that assayed $100 per ton. This was the best ore showing on the vein in either property. He also had a short adit on the vein, just west of the collar of the shaft. This had been driven in beyond where the vein split up and the ore pinched out. These were all the workings on the vein. The surface was covered with soil, and the only vein outcrop was in the creek, where it showed like a band of tiling in a floor. No surface cuts had been made on either property to show the outcrop of the vein.

My friend was a mining man of wide experience. He contended that in nearly all of the ore-shoots that he had studied, in mines that he had managed and in others that he had visited, in looking down the vein on the dip the ore-shoot nearly always pitches to the left-hand side. If his 'rule' applied to the case then under consideration, the shoot would pitch to the east, and he would lose the money invested in the prospect, and any more that he might put in on further development and in other payments to the owners.

From my study of the ground, the indications to me were that the main centre of disturbance and hot spring action had been west of the creek; I reasoned that the fissure vein in that vicinity would likely be open longer for ore deposition, and the chances were that the shoot would dip toward the nearest big ancient hot spring. I advised my client that he had better than an even chance to get all of the ore-shoot at depth. He made his payment, formed a company, and went ahead with the development work. At 200 ft. below the collar of the shaft it was shown that all of the ore-shoot of the Great Barrier company had crossed the creek.

Albion S. Howe.

San Francisco, November 14.

Some Words and Their Uses

The Editor:

Sir—The need of such an editorial as that entitled 'Some Words and Their Uses,' in your issue of November 11, struck me forcibly, on thinking of the habit generally prevalent here of calling a heavy oil, one of *low* gravity, and conversely, a light oil, one of *high* gravity. This is exactly the opposite of the truth, and has its origin in the use of the Beaumé hydrometer, by which a heavy oil of, say, 0.986 specific gravity is called a 12° oil, and a light oil of 0.830 specific gravity is a 40° oil. In M. L. Requa's article (page 644, issue of November 18), 'Present Conditions in California Oilfields,' I find the phrase, "the oil is 23° or higher in gravity." This is ambiguous, although probably 'higher' is intended to mean 'lighter,' and illustrates the point I am trying to make.

All the newspapers here announce the sailing of vessels to the 'antipodes,' meaning New Zealand and Australia. The true antipodes of California is near South Africa, New Zealand being the antipodes of Great Britain only. The true meaning, those whose feet are opposite ours, is entirely forgotten.

R. B. Symington.

San Francisco, November 18.

Along Mexican Trails

The Editor:

Sir—The article with this title in your issue of November 4 contains so many mistakes, both in the spelling of the Spanish words used and in the information given, that I hasten to request the author to first learn the language before attempting to insert foreign words into an article for a technical publication, and also to give correct data at the same time. In case he should at some future date want to write another article containing these words, I here give them correctly: *arieros* should be *arrieros; maize* should be *maiz;* and *arroya* should be *arroyo.* The word *antigua,* when not meaning one of the ancients, is an adjective, and the sentence commencing "This *antigua* is the * * *" should be written, 'This *mina antigua* is the * * *' or 'These *labores antiguas* are the * * *'

Furthermore, the name of the British company working the Rosario mine at Guadalupe y Calvo is wrongly given. It should be The West Mexican Mines, Ltd. The information that a 200-ton plant is being erected is also incorrect. About eighteen months ago there was much talk of a 500-ton plant, but owing to the revolution this was not gone on with. At present the sand from the dump is treated by cyanidation.

Donald F. Foster.

Parral, November 14.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

RUST stains may be removed from wood by washing the disfigured parts with a solution of 2 oz. of oxalic acid to 1 pint of hot water.

BLACK DIAMONDS are harder than white ones. Their color varies from dark gray and brownish opaque to black. They are found only in Brazil.

TO toughen plaster casts immerse them in a hot solution of glue until well saturated. When treated in this manner a nail can be driven into them without cracking.

TO drive a nail under water take a piece of pipe long enough to reach the timber, drop in the nail point first, then follow with an iron rod a little longer than the pipe and hammer the top of the rod.

IN order to find the number of revolutions of a pulley, when the diameter and drive are given, multiply the diameter of the driver by the number of its revolutions, and divide the product by the diameter of the driven; the quotient will be the number of revolutions of the driven pulley.

TO prevent blow-holes in cast steel, add to fluid steel an alloy of aluminum with a metal of the alkali earth group, or with lithium. Aluminum alone does not act upon the nitrogen and hydrogen in the fluid metal. The metals of the alkaline earths and lithium possess that property, but they are too expensive for use alone. An alloy of aluminum and calcium gives the combined effect of both elements, so that carbon monoxide and also nitrogen and hydrogen can be removed.

A WHITE METAL that has small shrinkage and is good for pattern plates consists of lead 90% and antimony 10%. A harder metal with small shrinkage and good for pattern plates is zinc 66% and tin 34%. A convenient amalgam for stopping up holes that cannot be easily soldered is made from filings of this alloy and mercury, kneaded in the hand into stiff dough, squeezing out all the mercury possible. This amalgam should be pressed, when first made, into the cavity and allowed to harden. When hard it may be scraped or filed like the metal itself.

CARBORUNDUM is manufactured by fusing in the intense heat of the electric furnace a mixture of granulated coke, pure glass sand, and sawdust. The first two materials must be the purest obtainable. The coke is the carbonaceous residue from the distillation of petroleum; the sand used is the purest glass sand. The sawdust is added for the mechanical purpose of making the mixture porous, thus avoiding explosions of the carbon monoxide produced during the course of the reaction. The fundamental reaction takes place between the sand (silica) and the coke (carbon), resulting in the production of a carbide of silicon, or carborundum.

THE world's production of spelter in 1910 was the largest in history, exceeding that of the record output of 1909 by 35,104 short tons, or 4.1%. The major part of this increase was contributed by the United States, which exceeded its production of 1909 by 13,424 tons, or 5.2%. Good gains were also made by Belgium, France, Spain, and the Rhine district, and smaller gains by other countries, no country failing to show some increase. The output of the United States was 30.5% of the total production of the world. The next largest producers were Germany, with 27.33% of the world's production to her credit, and Belgium with 21.53 per cent.

ZINC imported into the United States as metal or in ore may be entered for immediate consumption, in which case the duty is paid and the zinc goes direct to the consumer; or it may be entered for warehouse, bond being given for double the amount of the estimated duty. From warehouse the zinc may be withdrawn for consumption by payment of duty, or it may be smelted in bond, finally being either withdrawn for consumption or exported from warehouse with cancellation of bond. The zinc imported for consumption may be actually used in the country or it may be manufactured and exported, in which case the manufacturer is entitled to the benefit of a drawback of 99% of the duties paid.

SELENIUM is a rare and little known element which is chiefly used in the manufacture of certain glasses, to which it gives a red color, and in coloring enameled ware red. It is used to overcome the natural green color of ordinary glass and also in making glass of a distinct red color, such as that used on railroads for signal lights. Selenium has the peculiar property of being a poor conductor of electricity in the dark and a fairly good conductor in the light, and a number of electrical inventions depend on this peculiarity. It has been used in experiments in telephoning along a ray of light, and for transmitting sounds and photographs from one place to another by means of a telephone or telegraph wire.

CADMIUM has been recovered in the United States since 1907 by the Grasseli Chemical Co., of Cleveland, Ohio. The metallurgical method employed has generally been assumed to be fractional distillation, but this is not confirmed by the company, which prefers not to communicate the process used. Among the possible sources of cadmium in a general chemical works would be the slime left in the production of zinc chloride from zinc scrap and skimmings, or from low-grade roasted zinc ores. As dilute hydrochloric acid dissolves zinc in preference to cadmium, the cadmium content of the zinc scrap and skimmings is left behind in the slime. From this slime the cadmium may be recovered by distillation, by electrolysis, or by purely chemical methods.

TIRE-CASING that is old and not in a condition to warrant repairing by a regular repair-man can be put in condition to yield several hundred miles of service. If it is blown out, carefully clean the inside of the cover with gasoline for about 5 in. each side of the hole; then cut a section about 10 in. long out of the best part of a cover that is in bad condition, cutting beads from it and trimming it with a sharp knife at the edges to a thin edge. Carefully clean the inside with gasoline, and when ready apply three coats of cement to the inside of the casing to be repaired, allowing each coat to dry well; also two coats on the outside of the repair piece, and apply together as you would patch an inner tube. Rivet the patch to the tire-casing by using small copper rivets or split rivets in a single row, about 1 in. from the head, placing the rivets about 1½ in. apart. After this is done canvas should be cemented to the inside casing, covering the entire patch, so as to make a smooth surface for the inner tube.

IN THE ordinary method of galvanizing, where the material to be coated is dipped into a bath of molten zinc, there is great loss of zinc in the form of semioxidized skimmings and of hard drosses, caused by the alloy formed by the zinc with the iron of the tank and of the article being galvanized. In the larger galvanizing plants there are furnaces to refine these skimmings and drosses and to recover the spelter. There are also many small plants and some large ones which make a practice of buying galvanizers' skimmings and drosses and of recovering the spelter. A considerable quantity of old metal in the form of various alloys of zinc with copper and other metals is also worked over and brought up to the desired composition by the addition of new metal. At almost every brass foundry and machine shop in the country it is the custom to remelt and use brass filings, grindings, and scrap copper and brass, and it is manifestly impracticable to attempt to take full account of such material. Some of the zinc smelters running on ore find it advantageous to work in a quantity of secondary material.

Special Correspondence

LONDON

Failure of the East Rand Proprietary Company Discussed.—Impoverishment of the Rand Mines in Depth.—Important Evidence.

A great deal has been said about the failure of the East Rand Proprietary to make good its promises of profit. This is one of the great consolidations on the Rand and is in the control of Sir George Farrar and his friends. Early this year Sir George publicly promised his shareholders a regular dividend at the rate of 40%. No doubt he believed it could be done, though he was not unaware of the fact that in many sections of the mine the content of gold was not so great as had been expected. When the mill failed to give the necessary yield, all sorts of devices were resorted to in order to bridge the difficulty for a time, as it was confidently hoped that the mine would eventually respond and that the deficiency would be only temporary. The cyanide plant was crowded beyond its capacity, which only made matters worse, for it caused some of the gold in solution to be re-precipitated and thus lost in the tailing. This incident was not altogether unfortunate for the directors, because it afforded them a scientific reason for the failure to maintain the yield and allowed them to blame the metallurgists for poor work resulting in loss of metal. Another piece of diplomacy for postponing the evil day was to clean-up after the end of the month and to credit the month's tonnage of ore with the extra gold extracted during the next month. There have been a number of articles in *The Mining Magazine* and also in other papers, giving out these explanations, but at the Club the general explanation is that "the gold never was there, anyhow."

The discussion is now accelerated, for the latest sensation in the market has been a confirmation of this cynically-expressed view, in the shape of the unearthing of the testimony given by Frederick Hellmann before the Mining Industry Commission held at Johannesburg in 1907. Mr. Hellmann was at that time consulting engineer to the Farrar group, and he is well known in America. The proceedings of the Commission were held privately, but the report was published officially. Nevertheless, Mr. Hellmann's views as to the future of the East Rand group of mines as affected by the general principle of impoverishment in depth was never made public property. This suppression of important opinions inconvenient to the interests of the magnates is only too characteristic of the state of things in Johannesburg, where nobody but the controllers ever has a chance of getting into print. Mr. Hellmann in his testimony asserted that the decrease in the gold content of the ore with depth was obvious in all the mines on the Rand with which he was acquainted. He was severely cross-examined, but was firm. His phrases were characteristic of a practical man, rather than the nicely balanced expressions of a scientific geologist, but they are none the less noteworthy. Wherever he had been in the deep levels he had invariably found the grade decrease with depth. After Mr. Hellmann left, Sir George Farrar and Mr. Lionel Phillips, excellent business men, but neither miners nor geologists, told shareholders in the East Rand Proprietary in 1910 that their Angelo Deep had added to the evidence that the Witwatersrand series were not decreasing in value with depth, and that there was no evidence whatever that the gold contents at the deepest levels were not fully as high as they were within 300 ft. of the surface. The publication of Mr. Hellmann's opinion will serve two purposes; one to prove that "the gold never was there," and second, to revive the discussion started by C. O. Schmitt a year ago with regard to the general question as to the persistence of the content of the Rand deposits with depth. We shall in all probability hear a good deal more of the subject in London before long, and the discussion bids fair to become more vigorous than ever, for the matter is of vital importance in the future of the Rand.

SILVERTON, COLORADO

October Flood Causes Many Shut-Downs.—Railroad Activity.—Coal Shortage.—Work at the Mines.—Outlook Gloomy.

The flood of October has resulted in a great many shut-downs, especially of smaller properties, and the handicap of all the larger mines. The local railroads have been repaired, with the exception of the Silverton, Gladstone & Northerly, which connects the town of Gladstone and the Gold King mine with Silverton. This road probably will not be repaired before spring. Otto Mears has a force of 300 men working from Silverton toward Tacoma, and a force of 50 men is working from Tacoma toward Silverton. At present the forces are about ten miles apart, but progress is very slow and a train can hardly reach Silverton before December 1. There has been no suffering here, but the coal supply is low, many families already burning wood. There is an ample supply of foodstuffs, as the merchants have been packing from Ouray to the Joker tunnel and bringing supplies from that point on the Silverton railroad.

The Columbus, at Animas Forks, closed down on October 31, and this part of the district is now entirely idle. The Sound Democrat, under bond and lease to Ross & Nickels, has suspended operations for the present, and the lessees are in the East to raise money for further development next year. Train service to Animas Forks has been discontinued and will not be resumed until June 1912.

A LANDSLIDE BLOCK, SAN JUAN DISTRICT.

The Sunnyside, at Eureka, is operating steadily and storing concentrate. Work has begun on a zinc plant for this property. The United States Zinc Co. is installing the plant, which is expected to raise the percentage of zinc above 40, the minimum for profitable shipment in the San Juan. The Silver Lake is now milling more than 60 tons per day and has increased the force at the mine. The Iowa Tiger Leasing Co. has canceled its lease on the Iowa and Tiger mines, and the Iowa company is in possession. The company's future plans have not been published, but it is probable that the mines will be leased to one of the numerous applicants. The Gold King, at Gladstone, is working a few men, but little will be done until spring, unless the railroad is repaired. The Hercules has a few men on development work on the lower levels. The Silver Ledge is idle except for a small crew pumping water. The mine was flooded in October to a point about 40 ft. above the 5th level, and but little progress has been made in clearing it during the past month. The water is now down near the 5th level. A new double-drum balanced hoist is being installed, and when in place will be operated by electricity, thus dispensing with the use of coal at this property except for heating purposes. A new flume has been built from United States creek to the mill, and an ample supply of water is assured. The Southern Exploration & Mining Co., a new incorporation, has leased the Congress mine and has taken over all the interest of Maris and Goudy, former lessees. The property will be developed during the winter and efforts made to open up the big shoot 100 ft below the present workings. If successful, the new company will be an important shipper in 1912. November has been a month of heavy snowfall and this coupled with the railroad blockade makes operations exceedingly difficult. No returns from ore shipments are available to help on current expenses, and the coal supply is very short. The recent severe storms make the restoration of communication with Durango a slow matter, and it will be difficult, and in many cases impossible, for properties away from the railroads to lay in their winter supplies. This means a great many shut-downs, and it can hardly be claimed, even by the most optimistic, that the outlook for 1912 is a very bright one.

JARBIDGE, NEVADA

Outlook Is Promising, but Production Is Slow. Additions Being Made to Two Mills. Many Properties Capable of Making District Good Producer.

While in general the outlook for this district is encouraging, production is slow. George Wingfield recently came here and bought a group of claims for a quarter of a million dollars; Patsy Clark visited the district and secured a controlling interest in another group for half a million dollars; half a dozen Spokane, Butte, and Seattle investors have followed their example and have taken up properties at prices ranging from $50,000 to $150,000; but with all these big deals there has been so little actual money exchanged that it has not been noticed in the town. When the value of the mines is recognized so that properties can be sold for cash, or bonded at a reasonable price so that the usual 10% would be paid down, the district may show more life. The mines are here, but the prices are prohibitive.

One thing which has caused distrust is the lack of bullion shipments from the two big mills, which have received much advertising and which were completed some time ago. While it was believed that they would produce thousands of dollars' worth of bullion per month, one so far has done nothing, and the other has not paid expenses. While in many other districts evidences are to be found of the failures of stock companies in the erection of mills before the mines were discovered, intended to promote the sale of stock, it has been left to Nevada, and to one of the most promising districts of the State, to see two large mills built near high-grade milling ore deposits, neither of which is able to handle the ore. This fact is not because of the defects of the process, but because the mills cannot crush the ore to a sufficient fineness and in quantity large enough to supply the rest of the equipment. New machinery is being added to both mills, and they may yet be able to treat ore assaying $18 to $30 per ton.

There is another mill in the district, a small, 3-stamp, double-discharge, prospecting mill, said to be the property of one of the stock companies organized to operate here, which is still lying in the bushes where it was dumped from the freight-wagon last spring, surrounded by two feet of water. This outfit was used in Boise as an exhibition and sampling mill and did good work. If it were erected and treated the ore from any one of the twenty mines here, the district would produce a creditable amount of bullion. There are eight or ten properties now sufficiently developed and with ore of such value that if they belonged to some old Mexican miner, or to an old prospector, they would be producing with primitive machinery built close to the mine, and there would be no anxiety to sell stock. Any of these properties could be producing from $25 to $100 per day.

The Jarbidge district is just two years old, and as yet it has not 'found itself'. The outside investing public apparently has forgotten its existence.

BUTTE, MONTANA

W. A. Clark Making Plans for New Concentrator. Butte-Alex. Scott 10% Commission Again in Court. Boston & Corbin to Erect 300-Ton Plant.

Since his arrival in this city, W. A. Clark has been in consultation with mining experts and architects in regard to the erection of his proposed zinc smelter and concentrator. He will first build a concentrator for the purpose of treating the ore from his Elm Orlu mine, which has been closed down since the destruction by fire of the concentrator of the Butte Reduction Works. He has brought here from Jerome, Arizona, Thomas Taylor, superintendent of his smelting department at that place, as well as Thomas Peacock, head of the mechanical department. A visit has been paid to the Washoe smelter at Anaconda and Mr. Clark says the reason he made the tour of the smelter with the heads of department from Jerome was for the purpose of getting some ideas which might be useful in a big smelter he was building at Jerome. He said that he proposed to fit it up with the most modern machinery for the treatment of ore from his United Verde company property. Mr. Clark will not leave the city until he has completed his plans for the erection of the new concentrator.

The question of a 10% commission for the sale of the Butte-Alex. Scott property has been three times before the courts of this city and apparently is yet unsettled, as once more the case is to be appealed. Duncan McCrimmon claims to have discovered the orebody in that mine and made the fact known to James A. Murray, the millionaire mining man. He says that Murray informed him that he would pay him 10% if the property proved of value to him. The sale was made, and Murray denies having ever made any such promise to McCrimmon. The latter brought suit to recover the 10% commission, amounting to $15,000. When the case was first tried McCrimmon secured a verdict for the full amount claimed, but a new trial was granted. On the second trial McCrimmon again won and the judge refused to grant another trial. An appeal was then carried to the supreme court, and the new trial was ordered. In the third trial the evidence was practically the same, but a verdict was returned in favor of Murray, the jury standing eight to four. Now notice has been given of another appeal.

The Boston & Corbin property is now receiving attention at the hands of the Boston directors who have been at the mine for several days. The men who came to this city and later proceeded to Corbin are N. L. Amster, F. L. Dabney, Alfred Codman, Charles H. Cole, D. A. Ellis, and J. W. O'Neill. Plans for extensive development are being made, and it is about decided that a 300-ton concentrator will be erected in the spring. A thorough examination of the mine shows that there is enough ore broken in stopes or blocked out to keep a mill of that capacity going for several years.

A. B. Wolvin, president of the Butte & Superior company, while in the city recently, informed a close friend that ever since the company had been using the Basin Reduction Works concentrator about 85% of the mineral content of the ore was recovered, and that it was hoped to attain later a recovery of 90%.

A report received by M. W. Bacon, manager of the Heinze western interests, states that a rich body of ore has been discovered in the Stewart mine. The vein was found in the winze, and it is believed that the orebody may extend farther than the winze.

Shaft-sinking in the Pilot Butte is making good headway, the depth now being a little over 800 ft. The cross-cutting from the Black Rock mine of the Butte & Superior company through to the Pilot ground has reached a point about directly under the Pilot shaft, and through permission of the Butte & Superior company the work is to be continued to a point where it is expected to find the Berlin claim vein of the North Butte company.

The work of cutting a station on the 1800-ft. level of the Tuolumne mine has been completed and sinking resumed to the 2000-ft. level.

NEW YORK

Upward Turn in Market.—Reports of Copper Exports by Metal Exchange and Producers' Association Differ.—Tennessee Copper Co. as Record 'Low-Cost Producer.'

The past two weeks have seen the markets in the East taken in hand by some of the strongest factors and given a sharp upward turn. There has been much talk of the light shed on the legal tangle in corporate affairs by the consent of the Federal court to accept the plan of reorganization offered by the American Tobacco Co. It remains to be seen whether the encouragement derived from this particular source is justified. There are some, of pessimistic turn, who refuse to believe that, with tariff agitation sure to be one of the principal factors in the coming presidential campaign, with a growing clamor for criminal prosecution of the offenders against the Sherman law, it is possible for any big bull market to be put into action and receive the necessary degree of public support. These have, to a certain extent, seen their position justified by a decline.

The market in copper shares has been in line with the rest of the list, and it is quite evident that everything that could be utilized to encourage the holders of copper shares has been made to do double duty. Not very long since, some of the copper authorities abroad were inclined to question the disposition of some of the metal which is disposed of by way of export from this side. There is a marked discrepancy between the October figures of the New York Metal Exchange and those of the Producers' Association. The Metal Exchange export figures are 40,808,000 lb., instead of 60,084,349 lb. as reported by the Association. Probably this is explained by the varying periods of time covered. The customhouse clearings and the Association figures rarely agree, because the accounts are not made up for identical periods of time. Still, the fact remains that there is some criticism of the monthly report of the Producers' Association, and evidently a strong impression that the best foot is put forward all of the time for the copper interests.

It is true that there has been a marked increase in the demand for copper at home during the past few weeks, but nearly all of the buying is known to have been for delivery during the current year; it is safe to assert, therefore, that, notwithstanding the fact that most of the mining companies are sold out for the present, still consumers show by their attitude that they are paying no attention to prophecies of higher prices for metal. With 500,000,000 lb. of added production waiting for a market to justify its being mined, the consumer can listen unmoved to any arguments based upon the world's consumption of copper and its proportionate relation to the world's known ore reserves.

The opinion or belief that not all of the copper sent abroad was being accounted for in the visible supply as given out every fortnight on the other side, has evidently caused some little uneasiness. Boston telegraphic despatches say that a careful inquiry has been made of all producers and shippers on this side, and it is said that all deny the existence of a quantity of copper held as 'invisible supply' upon the other side. A letter from Merton & Co., London, is also quoted as saying that there is no cause for apprehension; that any stocks held and not duly reported and accounted for are so small as to be wholly insignificant.

It seems strange to refer to the Tennessee Copper Co. as a low-cost copper producer, still crediting by-products as simply reducing copper costs, as is done in nearly all mines where there are appreciable precious-metal values, Tennessee is probably the lowest-cost producer in the country. As a matter of fact, however, the company is first a manufacturer of sulphuric acid, and produces about a million pounds of copper monthly as a by-product. This year's production of sulphuric acid will amount to about 200,000 tons, and the company has a contract for the sale of all of its acid production for the ten years next ensuing. As the only successful copper mine in the Appalachian range, Tennessee Copper stands in a class by itself.

North Butte has been attracting much attention in the market. It is quite evident that there has been some real liquidation in the stock, quotations having broken from $36.25 to $23 per share. There has been some talk of passing the next dividend, but it is stated upon apparently good authority that no such action is contemplated. At the present time North Butte's production is about 2,000,000 lb. monthly, but costs are about 10c. per pound, which is not enough of a showing to warrant any very high price for the stock. Obviously, the future of North Butte hangs upon present underground work, where it is not as yet known what will be found in the Edith May and Jessie veins, both of which are to be opened at lower levels, ranging from 2400 ft. in the former to 2800 ft. in the latter. Six to ten months will probably be required to complete the development, and meanwhile the shares will be sold.

The promoters of Porcupine properties have been hoping for a revival of activity upon the strength of some open trading in the shares of the Dome Mines, Ltd., on the New York Curb. A number of the larger people interested in the Dome have just returned from Porcupine, and a little market has been made, apparently upon the favorable impression they received. Quotations have been ranging around $40 per share. The Dome mill is to be running some time in January next and will begin operations on $6 ore.

SALT LAKE CITY, UTAH

Silver-Lead Producers Gain Confidence. — Park City Developments.—Slow Progress in Drainage Adit.—Railroad for Deep Creek District. — Bingham & Garfield Increases Capitalization.

The steadying in the price of lead and the stiffening of silver have had a similar effect on the confidence of the silver-lead producers, and recent news centres around this class of mine. In Park City the Daly-Judge is cutting loose by starting a second shift on its concentrator. The company has been working a single shift, but the volume of milling ore is such that the mill could be supplied at even a greater rate. The company has piled up a surplus of about $400,000 and is earning around $30,000 per month, without figuring in the increased output of concentrate. The Thompson-Quincy, one of the newer companies of Park City, is undertaking an extensive campaign of development, under the direction of John McSorley, who had much to do with opening up the orebodies of the Daly West and the Daly-Judge. The Thompson-Quincy has arrangements whereby it is working its property from the Daly West, and secures drainage and an ore outlet through the Ontario drainage adit. A MacQuisten tube-mill is being installed by A. J. Miller and E. J. Beggs at the plant of the Grasselli Chemical Co., for the purpose of experimenting with some of the Park City ores and tailings. The first work will be with tailing containing some lead, but principally zincblende. The zinc problem is an important one to Park City, as so many of the properties contain large quantities of zinc-lead ores of a grade requiring economical treatment and a close saving to make them profitable. The Snake Creek drainage adit, which is aimed primarily at the west end of the Park City district, is making slow progress at present on account of bad ground. The work of concreting about 300 ft. of the adit is in progress, and this is not made any easier by the fact that 2500 gal. of water per minute is being handled. Negotiations are still in progress for an extensive merger of Alta properties. For a long time it has been recognized that the water problem, and the securing of depth and economical extraction of ores could best be handled by the merging of several properties. Reports have been made on several of the mines by various engineers, and options on some of the most desirable properties have been secured. There have been numerous conferences, but no decisive action. For several decades the people who have been interested in the Deep Creek mining district in western Utah have been talking about what they would do if they had a railroad. Now they are having their hopes raised by the appearance of railroad surveyors between Ely and Deep Creek, and there is much speculation as to whether this means Western Pacific, Tonopah & Tidewater, Nevada Northern, or something else.

The Bingham & Garfield road has increased its capitalization from $1,000,000 to $2,500,000. This road has secured the ore business of the Utah Apex, which means added net revenue to both parties to the contract. The road comes within a few hundred feet of the Parvenue tunnel of the Utah Apex, which company will save 20 to 30c. per ton on hauling. The annual report of this company shows a mining profit for six months of $121,299.57, net profit, $87,671.37. The mill is now working three shifts, and there is a steady output of shipping ore.

JOHANNESBURG, TRANSVAAL

Similarity of Rand and European Coal Deposits.—Eckstein Group Engages Welsh Engineers in Place of Americans.—Mining Methods Discussed.

Ever since mining operations on the Rand assumed a large scale, a strong similarity has been recognized as existing between its gold-bearing beds and European coal seams. The local banket beds are of sedimentary origin, and undoubtedly the Rand goldfield has been thrown into its present shape exactly in the same manner as the European coal basins. Below the oxidized outcrop on the Rand the yield of the banket beds of course has declined, and one school of mining engineers urges that only by reducing working costs per ton milled, can the highest profit be obtained. Another school urges that the best profits can only be obtained by keeping the ore sent to the mill as high in value as the mine can be consistently made to produce.

The Eckstein group of mines, representing most of the best properties on the Rand, seem to be trying both methods. Some of those who control the destinies of their mines, appear to consider that working costs per ton can best be reduced to their lowest limit and profits thereby increased by copying coal-mining methods. On this account the services of colliery mining engineers from England and Wales have been secured to direct underground operations. As this group has almost exclusively employed American engineers in the past to control the technical working of their mines, this introduction has naturally caused somewhat of a flutter in the American dovecotes.

The lines upon which underground mining operations in the past have been conducted, have been based with the object of making the yield as close and correct a representation as possible of the average value of the payable ore reserves, with the result that the operations underground have been somewhat scattered, although the results obtained have been wonderfully uniform. To secure these results, some of the large mines find it necessary to draw their ore supplies from as many as twenty different levels. Not only so, but several mines find it necessary to reopen many of the old levels near the outcrop to remove the pillars left years ago for the support of the hanging wall, so as to sweeten the low-grade stretches of ore unexpectedly found in the lower levels of the mines. Of course, such a scattered system of mining means increased cost in many different ways over what would have been the case had coal-mining methods been followed, and the whole of the valuable ore completely worked out when mining operations were originally in full swing upon these particular levels.

There can be no doubt, however, but that concentration of underground mining operations must reduce the costs of supervision, handling, and tramming the ore, particularly if the levels are driven, and the work concentrated, on the lines of coal mining, so as to admit of mechanical haulage being introduced on the levels. Possibly in some cases the reduction may amount to 2 shillings per ton. Absolute concentration on coal-mining lines must, however, mean under existing Rand conditions a varying yield, and when the operations are mostly confined to the low-grade areas so frequently unexpectedly encountered on the Rand the profits also must decline. It of course has happened that in many cases underground mining operations on the Rand have been allowed to become scattered and expensive, without justification, a fault somewhat common with metalliferous mining all the world over. It is just possible, however, that if uniform results are to be obtained concentration may make their attainment impossible. At all events, only the individual surrounding conditions of a mine can decide to what extent the underground operations can with advantage be concentrated and low working costs sacrificed for higher or uniform results. At the Nourse Mines, where concentration is to be carried out under the control of a colliery engineer, apparently with the principal object of reducing costs, the results will naturally be watched with some degree of interest.

GLOBE, ARIZONA

Live Oak No. 2 Shaft Sunk 928 ft. in One Month.—Inspiration Experimental Mill Being Enlarged.—Fifth Unit of Miami Mill Nearly Ready.

At the Live Oak mine a station is being cut at a depth of 800 ft. in shaft No. 2, which recently was sunk to a depth of 928 ft. for developing the western end of the orebody. A world's record is said to have been made in this two-compartment shaft by Ross and McIvor, who sunk it 206 ft. in one month. The shaft was sunk on a churn-drill hole, which penetrated the orebody at a depth of 705 ft., and showed it to be 210 ft. thick at this point. The first 100 ft. assayed over 3% copper, and the average for the entire thickness of 210 ft. is about 2¾%, which is considerably higher than the average for the orebody given in the report of July 1, which was 2.25% for 12,000,000 tons. W. S. Osborne, one of the Ray Consolidated engineers, made an independent sampling of the shaft for Hayden, Stone & Co., and his results are reported to agree very closely with those obtained by the Live Oak engineers and with the results obtained by churn-drilling. While no figures have been given out, it is known that the ore reserve has been considerably increased since July 1. The cross-cut west from No. 1 shaft has reached the orebody, which is now being developed at that point by driving and raising. Four churn-drills are being used in exploring and developing the western end of the property.

The corps of mining and construction engineers assembled at the Inspiration now numbers 16, and all are busy on preliminary plans and surveys. The experimental mill is undergoing alteration and enlargement, and a small force of men is engaged in preliminary construction work at the dam-site at Wheatfields. Plans are being made for the mining of the ore and a 36-in. gauge track is being laid on the main adit level. The last official report showed a reserve of 30,000,000 tons of ore with an average assay of 1.95% copper. The New Keystone Copper Co. is operating one churn-drill on its property lying between the Live Oak and the Inspiration. The result of this exploratory work is not made public. There is no work being done underground. The June report gave 2,000,000 tons of ore averaging 2.25% copper.

The Miami Copper Co., with four of the six units of the mill in operation, is maintaining a daily tonnage of 2000 tons, the recovery of copper content of the ore being over 75%. The fifth unit is all equipped and ready to run with the exception of the line shafting for the rolls and Chilean mills. This has been delayed in shipment, and as soon as it arrives it will be placed and the unit started. The fine-grinding in this unit will be accomplished in three 6-ft. Evans-Waddell Chilean mills with rollers much heavier than those in the Trent Chilean mills, with which the first three units are equipped. There are two mills to the unit. The fourth unit is equipped with 8-ft. Hardinge pebble-mills instead of Chileans. The fine-crushing in all units is done with Burch rigid rolls. A considerable part of the ore is coming from the dump at No. 2 shaft, which is mined by a 'glory-hole'. The small steam-shovel used in excavating for the mill has been moved to the rim of the hole and dumps the ore into the crater and down a raise, to the tramming level. The third Nordberg 1200-kw. generator is being erected in the power-house under the supervision of Frank Zlatnik, power-house superintendent, who for many years was erecting engineer for the Nordberg company.

General Mining News

ALASKA

Juneau

The Skagway Mining Co., capitalized at $10,000, has been incorporated by L. S. Keller, D. L. Dickeson, E. J. Shaw, and W. W. Boughton. Its principal place of business is at Skagway.

Prince William Sound

The Mayfield Gold Mining Co. has been incorporated by M. M. Reese, F. C. Weber, and J. W. McMillan. The company is capitalized at $1,000,000, and has its principal place of business at Valdez.

The Valdez Gold Mining Co. has been incorporated by C. Crawford, A. E. Grigsby, M. Blum, H. B. Ingram, and E. Smith. The company has a capitalization of $10,000, the shares having a par value of $10. The principal place of business for the company is at Valdez.

Seward Peninsula

The Seward Peninsula Dredging Co. has been incorporated with a capitalization of $300,000, with the shares having a par value of $100. The principal place of business is at Nome. The incorporators are Jafet Lindeberg, L. Stevenson, C. C. Lomen, Carl J. Lomen, and E. J. Cole.

The steamship *Corwin* has arrived at Seattle with tin ore valued at $47,000 from the Buck creek diggings, near Cape York.

ARIZONA

Cochise County

The Montana-Tonopah M. Co. of Nevada has paid the first installment on the purchase of the Commonwealth mine, near Pearce.

The 100-ton concentrator of the Paradise M. & M. Co. at Paradise made its initial run November 8. There is much activity at present in the district.

Gila County

(Special Correspondence.)—The latest official figure of the tonnage developed by the Live Oak Development Co. is 19,000,000 tons of ore averaging 2.11% copper. Of this amount over 15,000,000 tons will average 2.25% copper. These figures are given by Charles Hayden, of Hayden, Stone & Co. which financed the last two stock issues of the Live Oak Development Co. and which probably will complete the financing of that company. After his visit to the mine recently, Mr. Hayden announced himself as satisfied with the development to date and said that the Live Oak Development Co. could have funds for future development and equipment. Shaft No. 2, near the western end of the property, passed through 210 ft. of ore averaging 2¾% copper. A station is being cut in the ore at a depth of 800 ft. and this end of the orebody will be further developed. Development is in progress at No. 1 shaft, and four churn-drills are in operation.

T. R. Drummond, manager of the Inspiration, states that he expects that a site will be selected for the new mill and that construction will begin soon. The alterations of the experimental mill have been completed and J. M. Callow and E. J. Harrison will arrrive in a few days to supervise the tests.

Churn-drill hole No. 1 of the Southwestern Miami Development Co. is now 1160 ft. deep and has been in chalcocite ore for the last 50 ft. F. W. Hoar, the manager, said last week that the westerly continuation of the Live Oak orebody into southwestern Miami ground has now been proved beyond question. A wire has been received from Thompson, Towle & Co. to the effect that the stock would be listed on the Boston Curb, November 20.

Globe, November 18, 1911.

The New State Copper M. & S. Co. has been incorporated by H. Sutton, J. P. McNeil, J. R. McDonough, Wade Sotel, and T. Kelly, of Globe, and W. W. Jones, of Miami. The company owns 33 claims, on which some work has been done, about seven miles south of Miami.

Development will be resumed at once on the Warrior properties by the Warrior Copper Co., as the Warrior Development Co. has formally turned over the property to the former company. The Development company had until December 13 to make the final payment on the property. It is announced that shipments to the El Paso smelter will be resumed about January 1.

Graham County

Some trade authorities believe that the Arizona Copper Co., Ltd., property is to be equipped with a modern reduction plant, owing to the reported favorable views in regard to the matter held by L. D. Ricketts, general manager for the Greene-Cananea company, whose recent trip West is thought to have been in the interest of the Arizona Copper Co. Mr. Ricketts recently sailed from New York for Scotland.

Pima County

The Arivaca Gold Mines Co. has been incorporated with a capitalization of $1,000,000, with its head office at Tucson. The incorporators are J. M. Ruthrauff, C. E. Woodell, F. G. Godfrey, all of Tucson.

The Campo Bonito M. Co. has been reorganized and is known now as the Cody-Dwyer Mining & Milling Co. The company has a capitalization of $5,000,000 and no stock is for sale, it is reported, as each man in the company is a millionaire. It owns the Southern Belle and the Campo Bonito properties, making a total of 40 claims. A 100-ton mill for the Southern Belle and new converters recently were ordered by telepgraph. Two 40-ton mills are already on the Campo Bonito property. W. F. Cody, famous as 'Buffalo Bill,' is president of the new company; D. B. Dwyer, secretary and treasurer; W. H. Getchell, consulting engineer. Its principal place of business is to be at Tucson.

Yavapai County

Machinery for a 250-ton reduction plant has been purchased for the Yarnell mine, in the Weaver district, by its new owners, a syndicate headed by W. E. Sharps, who financed the Ray Central company. The syndicate, composed of Philadelphians, has made an appropriation of $150,000, it is reported, half to be expended for equipment and half for mine development. W. R. Twitchell is manager of the property.

CALIFORNIA

The State Mining Bureau has issued a report stating that the mineral production of California during 1910 was $88,419,079, against $82,972,209 for 1909. Kern county leads the list with $19,614,014. Fresno county is second with $9,505,699.

Nevada County

James Roach and his son Thomas recently picked up a nugget valued at about $1700 on the William Tell claim, between the Comet and Conlin mines, state reports from Grass Valley. The nugget weighed a little over 143 oz. It is affirmed that a piece of quartz of the same size would weigh only 4 lb., leaving 97 oz. of gold.

Plumas County

The 5-stamp mill recently purchased for the Oro Fino quartz claims on Hopkins creek will be in operation late in December, says a report from Quincy. The claims are owned by the six Hewitt brothers. Henry Hewitt has charge of the erection of the mill, which was bought in San Francisco.

San Bernardino County

Many mining properties in the San Bernardino valley are planning to use electric equipment, states a report from Bakersfield, as the result of the construction of power lines by the Southern Sierras Power Co., the Phipps company recently incorporated.

(Special Correspondence.)—Extensive oil deposits are reported to have been discovered near Daggett. A. Falkoner, of Daggett, Marcus Bluth of Los Angeles, and J. H. Flinn, of Barstow, are planning development.

Daggett, November 19.

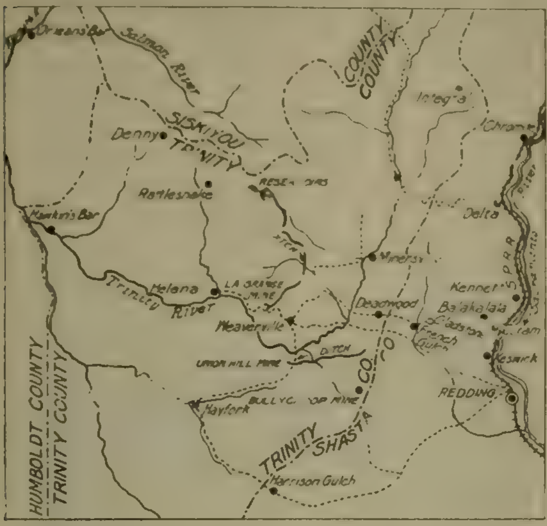
Sierra County

The Independence mine, on Wolf creek, about five miles from the Alleghany district, is now owned by the Independence Gold Mining Co. Fred A. Pearson is general manager for the company. Mr. Pearson and his associates had obtained a bond on the mine several years ago.

Fire last week destroyed the electric hoist and all other equipment, except the mill, transformer house, and superintendent's residence, of the Alaska mine, near Pike, causing a loss estimated at $7500. The company will rebuild at once. No lives were lost. J. Clippenstein, a pumpman, was in the mine when the fire broke out. Taking a safety razor from his pocket he shaved himself, and was found reading by one of the lights when his rescuers arrived. He said he knew "something was wrong," but could not find anything else to do.

Trinity County

The Trinity Con. Hydraulic M. Co., recently organized by W. A. Boland, has formally taken possession of the Hupp mine in Weaver basin. J. J. Murphy is to be superintendent of the property. The same company has several other properties in the Weaver basin, including the Headlight mine at Trinity Center. The price of the Hupp mine is reported to have been $100,000.



MAP OF TRINITY COUNTY.

Tulare County

The Himalaya mine of the White River district recently shipped chrysoprase valued at $7500 to New York jewelers. The consignment is said to contain the finest gems ever sent from the mine. The revival in popularity for these stones has brought about renewed activity in the mine, of which J. R. Merrill is superintendent.

Tuolumne County

(Special Correspondence.)—A temporary suspension of operations was caused at the Black Oak mine last week by a large inflow of water on the 1500-ft. level. The miners saved their lives by hastily retreating. The water, supposed to come from a subterranean reservoir, has about ceased flowing, and there will be no ill results other than the short interruption of work.

Repairs are being made to the machinery at the Bonanza mine at Sonora with a view to unwatering and working the property, in which Los Angeles investors are interested.

Development work soon will be in progress at the Carlotta-Pennsylvania. The improvements just completed consist of a new head-frame on a concrete foundation, a hoist-room and a change-room. A blacksmith-shop is being built and the construction of an elevated tramway to the mill will be commenced in a few days. A Leyner machine-drill and a new Matteson roller-bearing lever-dumping car have been added to the equipment. After sinking 200 ft. a cross-cut will be driven from the bottom, 400 ft. below the surface, to a point directly underneath the Pennsylvania shaft, which will then be connected by a raise. R. B. Whitman is superintendent of the property. The Sunnyside mill is now in operation. The Watt mine, near Soulsbyville, has been sold at sheriff's sale to satisfy a judgment against E. A. Hanke. The property was bid in by J. J. Rauer of San Francisco for $97.50.

Work has begun on the electric transmission line to supply power to the Slap Jack mine near Groveland, and a new head frame is being erected.

It is reported that operations will shortly be resumed at the Mitchell mine, situated in the western part of the county, ten miles from Keystone. The Clio mill will be in commission soon, the repair work being nearly done. Development is also in progress.

The vein at the Jim Lyons mine, near Confidence, is being opened by an adit, which is now in 80 ft. The vein is 4 ft. wide and free gold is easily visible in the rock. The erection of a mill is planned. The property was bonded several weeks ago to A. H. Russell, of San Francisco, for $75,000.

Tuolumne, November 18.

(Special Correspondence.) Development at the If I Can property is progressing favorably to make the same a good gold producing gravel mine. The boarding, bunk, and dwelling houses are in the course of construction, with an office building complete. A tubular mill has been installed as the means of breaking and crushing the cemented gravel. D. W. Kelly is manager.

Chinese Camp, November 18.

COLORADO

Clear Creek County

(Special Correspondence.)—The Humboldt mine on Ute creek has been taken over by N. L. Bernard, of Chicago, representing a syndicate of capitalists. A new adit is to be started to intersect the veins at a vertical depth of 1000 ft. The mill will be provided with three new tables, and a compressor plant is to be purchased. K. E. Seemann will serve as resident manager. The Victor mine on Virginia canyon has been taken over by the Pike L. Co. A plant of machinery will be purchased and the shaft will be sunk to a depth of 200 ft. From the present workings ore is being shipped that mills 2.50 oz. gold per ton. J. Woolcock has started shipments from the Cook vein of the Stanley mines that mills $35 per ton in gold and silver. Work is to be resumed on the Cumberland mine in Alice district by A. Holden. A 12-in. streak of ore that mills $120 per ton in gold and silver has been uncovered on the Oneida mine at Lamartine. A shipment of one carload of smelting ore is being made each day, that assays about $70 per ton. Shipments have been started from the King Bee property on Seaton mountain and returns of $40 per ton in gold and silver are reported. Edwards & Co. are operating under lease. The Puritan mine at Alice is showing large reserves and shipments are to be started. George Steuart is manager.

Idaho Springs, November 18.

In extending the adit of the Geneva mine on Alpine mountain, ore assaying as high as $15,000 per ton was found recently, state press reports. The mine is in the Georgetown district. It is owned by Mrs. William Aldred.

Fremont County

J. F. Shafroth, governor of Colorado, has appointed Mr. Dalrymple, State Mine Inspector, and John Wilson to investigate the grievances of the coal miners in regard to screening coal. The mines are largely those owned by the Colorado Fuel & Iron Co. A thorough investigation of the district is to be made.

Montezuma County

Under the new act allowing the Secretary of the Interior to permit development of natural resources in the National parks, the coal tracts in the Mesa Verde national park are supplying the town of Colfax with fuel, states a report by Mr. Wright, acting superintendent. During the year ended July 1, 226 tons of coal was produced. Mr. Wright advocates the relinquishing by the Government of territory surrounding Mesa Verde, as he believes the recent treaty with the Utes will bring under Federal jurisdiction more valuable property than that immediately surrounding the park, and the small ranger force makes it impossible to properly police the surrounding country. He suggested that Congress appropriate $41,615 for the maintenance and improvement of the park during the fiscal year ending June 30, 1913. The park office is at Mancos.

SUMMIT COUNTY

The magnetic separator of the Wellington M. Co. will be ready for operation late in December, according to recent reports from Breckenridge. The company has resumed sinking its main shaft with three shifts. The concentrator now is treating about 95 tons of ore per day.

The Reliance Gold Dredging Co.'s boat is to continue operations through the winter. The French Gold Dredging Co. soon will be working in the old channel, the scene of early-day placer mining. The Buffalo Gold Placer M. Co. has stopped operation for the winter. The Standard mine, on Gibson hill, is shipping about six cars of lead carbonate ore per month. To open the Oro vein a new shaft is being sunk on the Louis D. placer property in French gulch.

TELLER COUNTY (CRIPPLE CREEK)

The properties leased by the Western Investment Co. shipped in October 50 cars of ore. Of these, 15 cars were from the Ophir mine, and brought returns of about $40 per ton.

Milling-grade ore, in a 4-ft. vein, recently was found in the Jefferson mine, near Victor. The property is leased to W. R. Davenport.

An experimental mill for treating ore from the Christen adit is to be erected by the Signal King G. M. Co., which owns property on Signal hill, opposite the Moffat adit.

In another attempt to shut off the foul gases which have prevented the Moose mine from being operated, Peter Busch, superintendent for and a director of the company, has bulkheaded the shaft at the 600-ft. level, timbered the station with tight boards, lined it with heavy building paper to make it airproof, and laid a tight flooring. The Moose, under certain atmospheric conditions, could not be worked, although over $7000 has been spent in attempts to obtain adequate ventilation. It is operated by lessees.

Work on the Arapahoe claim of the Jerry Johnson M. Co. has been resumed at the 450-ft. level. The claim has been subleased to E. S. James. The Aetna G. M. Co., on Mt. Ervay, has resumed operations. Ore assaying as high as $27 per ton is reported mined. A rich discovery recently was made at the Jo Dandy, according to press erports.

The Mable M. estate, Beacon hill, in October shipped 44 cars of ore. The Stratton's Independence mine, which was filled with water in 1907, and which since has been idle, recently resumed work on the 1050-ft. level.

A heavy flow of water was found recently in driving the Roosevelt deep-drainage adit. T. R. Countryman, U. S. deputy mineral surveyor, made an official inspection for the Cripple Creek Drainage & Tunnel Co., and announced that the flow is 7900 gallons of water per minute. The increased flow has had a direct result on the mines on the district. At the Portland G. M. Co.'s property the water at the 1500-ft. level of the No. 2 shaft is now about 30 inches deep.

Ore assaying as high as 35 oz. gold per ton was discovered at a depth of 1335 ft. in the Roosevelt deep drainage adit, within the property of the El Paso Con. G. M. Co. The point where the ore was found corresponds to about the 2300-ft. level of the Bull hill mines.

IDAHO

BONNER COUNTY

(Special Correspondence.)—John M. Duthie, of Libby, and Arthur B. Corey, of Butte, mining engineers, with a force of men, have been testing in the past week the ground in the vicinity of Kootenai falls for placer gold. It is supposed that the test is being made in connection with the litigation over the power-site at the falls. The tributary land is claimed by the St. Paul, Minneapolis & Manitoba railroad and the Great Northern railroad under a land grant, but the Government is contesting this claim. Joseph A. Coram, of Boston, claims the land under placer locations and has announced his intention of erecting a $6,000,000 power-plant at the falls next year.

Libby, Mont., November 18.

CANYON COUNTY

A smelter is to be built at Nampa, by the Northwestern Smelting & Refining Co., incorporated for that purpose. The company has a capitalization of $10,000,000, under the laws of Idaho. A bond issue of $5,000,000 has been arranged, and the company is said to have a guaranteed tonnage of 2500 per day. The plant will cover 42 acres. The company has its own coalfields and iron and lime beds along a railroad now in operation. Charles H. Gage is general manager for the company.

IDAHO COUNTY

The Idaho-Comstock M. Co. this winter will continue the cross-cut adit, started last year and now in 500 ft., to a length of 1300 ft. The company has 14 claims. Thomas H. Minear is manager of the property.

The Elk City reduction plant made its first run November 1. There is a quantity of concentrate at the plant for treatment, but comparatively little ore has been brought. Mr. Tytler is manager of the plant. The plant is owned by the Elk City Reduction Company.

SHOSHONE COUNTY

The Lead-Silver M. Co. is employing a force of about 50 men and will sink the shaft 200 ft. deeper. Shipment of ore has been resumed.

A compressor will be erected at the Amazon Manhattan property as soon as the Washington Water Power Co.'s line reaches the property, which should be in the near future. The company also is planning to build a mill. The property recently was acquired by William T. Tracy, of Galesburg, Illinois. Mr. Tracy has just made an inspection of the mine, which is in the Sunset district.

A new compressor has been erected on the National M. Co.'s property, near Mullan, and a motor will be installed within a month. Two shifts are now driving the adit, which is in about 300 ft. Another 1200 ft. will have to be driven before the adit is under the orebody. The new adit is about 100 ft. below the old workings.

One of the most important discoveries made for months at the Stewart mine was made recently when exceptionally rich ore was found in a vein cut by the winze, according to reports from Wallace. The new adit is being driven at a rate of about 400 ft. per month.

MONTANA

LINCOLN COUNTY

(Special Correspondence.)—W. H. Graham, who recently bought the Wm. Criderman placer claims on Libby creek, states that he will have a fully equipped hydraulic plant in operation by the latter part of next April. Paul D. Pratt has already completed the survey work.

Libby, November 17.

NEVADA

CHURCHILL COUNTY

A preliminary estimate, recently issued, for October, the first full month of operation of the Nevada Hills Mining Co., shows that the company treated 2735 tons of ore, which milled $25.98 per ton, showing a recovery of over 91%. The net profit for the month was $41,062. The operating cost, exclusive of the cost of construction and the sinking of the Webber shaft, was $10.97 per ton.

CLARK COUNTY

Nels Nelson is about to start development work on his Graphic group of claims, adjoining the Red Cliff, three miles east of Searchlight. He has four tons of ore from the Louisa mine at the Cyrus Noble mill, the product of recent assessment work, from which he hopes to judge the value of the mine.

Carleson & Lund, lessees on the Quartette, have set up a windlass and are sinking on the vein. They have three tons of ore ready for the mill.

Esmeralda County

A deep working shaft and other development work will be started on the Silver Pick property early in January by the new owners, state advices from Goldfield. The property recently was secured by San Francisco investors headed by Herman Zadig. The deep shaft is planned for the Deserted claim, which adjoins the Pipe Dream fractional claim of the Silver Pick and the Mohawk claim of the Consolidated.

Rumors of the proposed merging of various properties are circulating. Among the companies mentioned for two or three mergers planned are the Lone Star, Blue Bull, Atlanta, Kewanas, Simmerone, Grandma, and Oro.

The Goldfield Merger Co. recently extended the time for exchanging stock on the St. Ives G. M. & M. Co. for stock in the Merger company to December 13.

Humboldt County

The Rye Patch M. & L. Co. has purchased a 10-stamp mill. C. A. Conlin, president of the company, recently stated that the company has 210,000 tons of ore on the dump of the old mine, which in a sample assay returned $8 per ton. It is believed that in the mine there is a large quantity of similar ore.

Lyon County

The stockholders of the Yerington Copper Co. have received notification that the controlling interests have organized the New Yerington Copper Co. with the same capitalization and that stock may be exchanged at the rate of one share in the new company for every two shares in the old company. By this arrangement the control of the new corporation will be retained in the treasury, and the stock will be used for development. Stock in the new company is assessable, but it is stated that it is hoped production will pay for development.

TONOPAH BELMONT SHAFT.

Nye County

The pool of stock of the Dexter White Caps M. Co. has been dissolved by unanimous consent of the directors, according to a recent statement issued by the company, and all who are entitled to stock may obtain it on and after November 30.

The Tonopah M. Co. in October produced bullion to the value of $220,450, according to a report just issued. The net profit for the month was $153,536. During the month 15,261 tons of ore was milled, the average recovery being $18.86 per ton. The bullion production amounted to 297,075 oz., valued at $220,450, and the concentrate to 87 tons, valued at $43,855.

The Tonopah Belmont Development Co. in October produced ore valued at $302,952. The net profit for the month was $163,799. The mill treated 7774 tons of ore, and 2550 tons was shipped to the smelter, making a total of 10,324 tons. The net profit shows an increase of $18,826 over that of September, and $10,193 over that for August.

The Montana-Tonopah M. Co. has declared a dividend of 6c. per share, payable December 20, to stockholders of record December 5. The company November 14 paid the first installment on the purchase of the Commonwealth mine near Pearce, Arizona.

The Tonopah district last week produced 8617 tons of ore, valued at about $215,425, the shipments being divided as follows: Tonopah M. Co., 3400 tons, Belmont G. M. Co., 2650 tons, Montana-Tonopah M. Co., 1030 tons, Tonopah Extension, 987 tons, West End, 500 tons, Midway, 50 tons.

A body of unusually valuable ore has been discovered in the North Star mine on the south cross-cut from the top of raise B.

Storey County

The only production reported by the Comstock mines last week was from the Ophir, which produced 406 tons of ore, assaying on the average $42.13 per ton, making the total production $17,105. Development work occupied the rest of the mines.

White Pine County

The Greek-American M. Co. is shipping ore from the Davis group at Aurum, state advices from Ely. The company is hauling the ore over a road which it built at a cost of about $4000 to Warm Springs, on the Nevada Northern, a distance of 14 miles. A vein recently found at the 110-ft. level has ore containing silver and lead and assaying between $5 and $10 in gold per ton.

Press reports state that a new vein carrying native copper in larger quantities than the original vein has been discovered by the Boston Ely company.

The Boston Nevada M. & M. Co. has started the construction of a mill near Osceola. The plans are in charge of C. L. Buckingham of Denver. The details of the structure have not been announced.

NEW MEXICO

Grant County

J. W. Kniffen has purchased a 50-ton cyanide plant for the Hinckley property at Steeple Rock. The mine has been operated for two years by the present owners, the American Exploration & Mining Co. The Last Chance mine, in the same district, recently erected oil-engines on its property.

Lincoln County

Bryan brothers have completed assessment work on the Cash Entry group. The work was done in the adit, in which the vein shows small, but consists of high-grade copper ore. John H. McCutcheon, owner and manager of several properties, is mining lead-silver ore which also carries some copper. C. M. Ryan and Tom DuBois are developing a promising prospect on the west side of the Gallinas mountains. The property has a lead sulphide ore which carries some silver and gold. The iron properties are seeing some activity.

OREGON

Baker County

For the first time in three years the aerial tramway at the North Pole mine is in operation, and the mill will be working in the near future. The force will be increased to about 60 men.

A rich vein, assaying as high as $100 per ton, has been found on Cabell mountain, Granite district, by F. E. Cabell, states a report from Sumpter.

Mining will be resumed, when the spring floods start, at the North Fork placer mine, in which C. D. Snyder & Sons, of Parma, Idaho, has just secured a two-thirds interest. The mine is nine miles from Granite.

Development of the Gold Bug property, on Rabbit creek, has been postponed, states R. B. Wallace, of Marshallton, Iowa, who recently inspected the mine. Only assessment work will be done for the present.

Josephine County

A. J. McCorkle and associates have taken a bond on the Gold Drift quartz mine, owned by W. T. Turnham and S. C. Stone, state recent reports from Grants Pass. The price of the mine is said to be $10,000.

UTAH

Juab County

The Eagle & Blue Bell mine, in the Tintic district, is shipping at the rate of four cars of ore per week, state recent reports, most of the ore coming from the 1300-ft. level. Imer Pett is manager of the property.

Ore assaying 178.8 oz. silver and 8.7% copper per ton was discovered in a cross-cut on the 280-ft. level of the United Tintic. The ore is from the Aspinwall vein. The United Tintic is a consolidation of the Bullock, Tintic, Empire, and Tintic Combination companies.

Recent developments in the Iron Blossom mine indicate that the 600-ft. level will rival the 500-ft. level, state reports from Eureka. While the ore so far mined assays about 10% copper, it is believed that an average assay of the face of ore showing today would return about 20% copper. Prospecting was recently carried on at the 1900-ft. level, but there will be no development at that depth until more machinery is installed, as the equipment is taxed by the present production.

The Gold Chain and Grand Central mines last week shipped 14 cars of ore. The Mammoth last week shipped 8 cars of ore, state reports. The electric pump at the Swansea, which was stopped for repairs, is now working. The other mines are active.

SALT LAKE COUNTY

Ernest R. Wooley, of Salt Lake City, former president of the Nevada Utah M. Co. is under indictment, charged with the larceny of over $14,000 of the company's funds. The complainant is the corporation itself. The complaint contains the allegation that as president he bought properties adjoining the Manhattan group in behalf of the company and that he represented that the properties cost him $15,000 when he paid only $300 for them. He is alleged to have received $15,000 from the company.

SUMMIT COUNTY

The Thor M. Co. has ordered 16 claims surveyed for patent and has let a contract for driving the lower adit an additional 150 ft. The property joins the Daly-Judge.

WASHINGTON

STEVENS COUNTY

The Tungsten Con. Co. of Loon Lake is reported to have uncovered a series of veins containing high-grade tungsten ore. A 60-ton mill is under construction, and it is believed that 4 tons of concentrate per day can be produced when the mill is finished. The mill will be equipped with electric furnaces. W. A. Brockway is manager for the company.

CANADA

BRITISH COLUMBIA

Development work at the Indian Mines has been suspended until supplies can be transported over the snow, says a report from Stewart. George Clothier is manager of the property. Harry Smith and E. Bunting have received another installment of $8500 in payment for the Hercules mine. Development work will be started in the near future. The adit of the Northern Terminus is now in about 45 ft. and the breast is in ore. There probably will be no cessation in development work. Work has closed for the season on the American creek property. Plans for a concentrator for the Ben Bolt mine are being considered by that company. Work is being done on all three levels of the mine. The adit at the Cascade Falls property is being driven to cut the vein at a depth of 80 ft. Frank Hume is superintendent of the mine.

MANITOBA

Quartz assaying as high as $122 in gold and 44c. in silver is reported to have been found recently along the east shore of Lake Winnipeg, thirty miles from Winnipeg, by E. A. [illegible]. The claim from which the samples were taken is known as the Gabrielle Mineral Claim. The proposed extension of the C. N. R. railroad will run through the mineral belt.

ONTARIO

The Temiskaming M. Co. of Cobalt has acquired a controlling interest in the North Dome Mines, Ltd. The price has not been announced.

The Rea mine, in the Porcupine district, has cut its No. 1 vein on the 300-ft. level, 75 ft. from the station. The vein at this point was about 25 ft. wide and carried some free gold.

The shipments of the Cobalt and Kerr Lake districts during the month of October amounted to 70 cars, or 2175 tons. The larger amount of ore shipped was high grade. The McKinley-Darragh was the leading shipper, with a total of 10 cars of high-grade ore.

The silver production for the Province of Ontario for the nine months ended September 30 amounts to 23,185,890 oz., valued at $11,593,286. This output makes a record for the camp. It is estimated that the production for the year will be about 3,000,000 oz. above that for last year, which is the present record for twelve months' output, 30,051,417 oz. of silver. Of the production for the nine months specified, all but 41 oz. came from the Cobalt, South Lorraine, and Gowganda districts.

The Crown Reserve M. Co. will pay a dividend of 2% and a bonus of 3%, amounting in all to $88,440. Similar dividends were paid November 15. The December dividend will be the twenty-second paid by the company and will bring the total dividend disbursements up to $3,626,061.

Press despatches state that the Seneca-Superior Silver Mines, Ltd., has acquired the three leases of the Kerry M. Co. on Peterson and Cart lakes. Development will be resumed in the near future on these properties, which cover about 30 acres. Two of the three leases are on property on Cart lake, adjoining the Gould property. The third is on property adjoining the Little Nipissing.

In the Swastika district visible gold has been found on a 20-ft. vein on claims adjoining the Reeves properties on the west. These claims are held by the Matabanick Gold Mining Syndicate. It is reported that this vein has been stripped for a distance of 500 feet.

YUKON

F. H. Kitto, inspector of Yukon surveys, has completed the survey work which he started last July in the Klondike watershed from Dawson to the mouth of Lee creek, including the north fork of the Klondike to the head of Benson creek. G. W. Tyrrell was his assistant.

MEXICO

CHIHUAHUA

The Chihuahua M. Co.'s property and the Potosi M. Co.'s property are being examined for London investors, state recent Mexican reports. L. Maurice Cockerell, of Chihuahua, is making the examination.

The smelter of the Corrigan-McKinney syndicate at Terrazas station was blown in on November 8.

The erection of a 10-stamp mill at the Capitanena property in the San Francisco del Oro district will be commenced shortly. The machinery for the mill has been ordered. A gas-producer power-plant is planned. D. H. Bradley, Jr., is manager of the property, which is said to be a bonanza.

Howard Sharp and J. S. Whitley have denounced 12 *pertenencias* in the Cusihuiriachic district, state recent reports from Chihuahua, and will call the property the Bella Vista. Jose B. Rascon has denounced 8 *pertenencias* in the Uruachic municipality, district of Rayon, under the name of Viente de Noviembre.

SONORA

At the Alacran shaft of the Mexican Metals Co. a find of fairly rich ore was made, according to an announcement made by August Fritsche. The Calumet & Sonora found valuable ore on the 60-ft. level of the Catalina No. 2 shaft. There now is a full breast of ore, although the orebody has been penetrated for 10 ft. The Cosac M. Co. has been organized by D. A. Richardson, of Douglas, Arizona, and his associates. The property is in the El Tigre district. E. B. Holt, of Magdalena, has organized the Arizona-Mexico Mines Co. to operate properties in Sonora. L. B. Garside of New York is associated with Mr. Richardson. It is reported the first development will be in the old Klondyke district. The Mesa-Rica company is about to increase the capacity of its mill, about 35 miles south of Moctezuma. A. C. Tanner is in charge of the work. The material has been delivered.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

Edwin E. Chase is at Parral.

Francis Drake is in New York.

H. W. Chadbourne is in New York.

F. L. Ransome is at Tombstone, Arizona.

D. H. Bradley, Jr., has returned to Parral.

E. J. Collins was in San Francisco recently.

C. E. Rodgers is at McKenzie, North Dakota.

George T. Coffey has returned from Dawson.

Milton M. Detch, of Goldfield, is at the St. Francis.

E. T. Corkill has returned to Toronto from Pittsburg.

L. D. Ricketts has sailed from New York for Scotland.

B. W. McLean, of Quincy, California, is in San Francisco.

G. H. Garrey has returned from Plumas county, California.

Hiram Hixon was in San Francisco, and has gone to Tacoma.

G. Blanchin was in San Francisco recently and has returned to Paris.

T. W. Fitzgerald, formerly of Guanajuato, Mexico, is at Sandon, British Columbia.

G. W. Egenhoff, manager of the Original mine, near El Portal, is in San Francisco.

Howard D. Smith has gone to San Joaquin valley, and will continue east to New York.

T. G. Brown is now with the Creston Colorado Company, at Torres, Sonora, Mexico.

A. C. Veatch is with the United States Geological Survey, at Washington, District of Columbia.

A. M. Yonge, of the Lightner Mining Co., has just returned from New York and Pittsburg.

Edward S. Wiard has removed his office from 417 Boston building to 422 Boston building, Denver.

W. B. Bretherton has accepted a position with the Dome Mines Co., Ltd. at Porcupine, Ontario.

H. S. Derby has quitted engineering practice and will practice as a consulting attorney at Sacramento.

W. H. Hutchings has accepted the position of general manager for the Ohio Mining Co., at Pearl, Idaho.

William H. Blatchley has left Tonopah, Nevada, for Mexico, where he will be traveling for some weeks.

C. H. Munro expects to leave Nikolaievsk in December and will return to San Francisco later in the winter.

Desaix B. Myers has been engaged in examination work in Calaveras county and has returned to Los Angeles.

Victor C. Alderson, president of the Colorado School of Mines, together with James T. Smith, visited Creede, Colorado, last week.

Charles S. Smith, of Boston, president of the Old Dominion Mining Co., is in Globe, Arizona, making an inspection of the property.

Edward M. McIlwain has resigned the presidency of the Universal Vanadium Co. to accept the presidency of the Lehigh Coke Company.

J. R. Edwards is now the head foreman at the concentrator of the Veta Colorada Mining & Smelter Co., at Parral, Chihuahua, Mexico.

John McSorley has been engaged as general superintendent for the Thompson-Quincy Consolidated company at its property in Summit county, Utah.

John D. Wanvig, Jr., late superintendent for the Superior & Boston Copper Co., has become associated with the firm of Weed & Probert in Los Angeles as their chief assistant. He will accompany Mr. Probert on his trip to the Guanajuato district in the interests of the Proprietary Mines Company.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press.

Mechanics' Lien on Mining Property

The statute of Montana gives to any person performing any work on, or furnishing any material for, any building, structure, mining claim, etc., a lien on such property. Under this statute persons making repairs and alterations in a mining claim, building roads, and preparing fuel for use in carrying on the mining enterprise and keeping the machinery in order and clearing away débris accumulating from time to time about the buildings and machinery, are entitled to liens for such work. And the limitations prescribed in the statute defining the property affected by a mechanic's lien, and providing that where the interest of a person owning the structure is less than the fee, the liens affect his interest only, do not apply to mining claims. A lien on a mining claim extends to the whole claim, as such claim cannot be divided and the improvements or structures erected thereon cannot always be removed. And under this statute persons so employed and performing such services where a group of mining claims are improved as a consolidated claim, are entitled to hold a lien on the entire group of claims. In order to enforce such liens the person performing the work must file a just and true account of the amount due after allowing all just credits. But this does not require the character of the work done to be classified or even the items of it to be set out in the account filed, and such an account need not specify the amount due for each kind of work whether construction work, or on repairs, or in road building.

McIntyre *v.* Montana Gold Mountain Co., (Montana) 108 Pacific, 353.

Injury to Miner—Liability of Operator

A mine operator was not liable in an action for injuries to a miner injured while hoisting timbers by means of a rope and a block with a pulley, where the evidence showed that a similar rope had been used by other miners for a long time with profit, efficiency, and safety, and that while it was not as well adapted for the work as it would have been had it been fitted with an iron or steel attachment it was not obviously dangerous and the mine operator was not negligent in failing to furnish a rope with iron or steel attachment. And in no event would the mine operator be liable where the evidence showed that the timber escaped because the rope was not properly tied by the miner; neither would he be liable where the evidence showed that the timber escaped from some unknown cause. To make the mine-owner liable in such case it is necessary not only to show that the miner was injured during the course of his employment, but that the injury was proximately caused by the negligence of the mine operator.

Cummings *v.* Reins Copper Co., (Montana) 107 Pacific, 904.

Cutting Timber from Mineral Lands

The authority given by the United States statutes to cut timber upon mineral lands not subject to entry except for minerals does not extend to land adjacent to lands valuable for mineral purposes, but only includes lands known to be themselves valuable for minerals, which are the only lands excluded by the United States statutes from any but mineral entry.

United States *v.* Plowman, 30 Supreme Court Reporter, 299. Feb. 1910.

Injunction to Prevent Mining

An injunction to prevent the mining of coal was properly refused where the bill itself showed that no mining had been done for a considerable length of time, and where the evidence and the answer showed that it was not the intention of the defendant to prosecute mining operations in the future.

Safe Deposit & Trust Co. *v.* Mehaffey, (Penn.) 76 Atlantic, 862, Jan. 1910.

Commercial Paragraphs

An interesting aerial tramway has recently been installed at the mine of the Montana Coal & Iron Co., Washoe, Montana. It was necessary to dispose of many tons of slack coal daily, and a Broderick & Bascom Rope Co. tramway of the two-bucket type was used. The carriers operate back and forth on stationary track cables 1½ in. diam. They are pulled by a ⅝-in. cable, operated by a 15-hp. electric motor. Only one attendant is required. He controls the flow of material when the buckets are being loaded, as well as the power and speed of the line. The tramway is 1200 ft. long, with an hourly capacity of 25 tons. There are three intermediate supporting towers varying in height from 15 to 42 ft. Each bucket has a capacity of 40 cu. ft., approximately 2700 pounds.

The owners of The Bucyrus Co., in association with strong Eastern banking interests, have just completed a plan of recapitalization. The stock of the company will be increased to $10,000,000 authorized, $8,000,000 issued. For some years it has been evident that with its rapidly increasing business, the company must add to its plant and equipment. New shops are now being erected at Evansville, Indiana, which will be owned and operated by the company in addition to its plant at South Milwaukee. The site comprises 70 acres, and it is expected that the new shops will employ 1000 men. Large purchases have been made of material and patterns for the manufacture of wire-rope shovels as well as chain-shovels.

The Bucyrus Co. now builds dredges of all sizes and types, wrecking-cranes, pile-drivers, drag-line excavators, ballast plow-unloaders, and steam-shovels of the heavier types, for which it has a world-wide reputation. It purposes to bring out a full line of light revolving shovels, weighing up to 40 tons, and it will also take up the manufacture of other types of earth-handling and excavating machinery. It intends hereafter to give more active attention to the development of export business. With increased facilities and augmented capital it will be able to extend its business to all parts of the world. The interest of new and influential stockholders in the East has been secured through the banking houses of Pomroy Brothers in New York, and Edward B. Smith & Co. of Philadelphia. The personnel of the new company will be as follows: H. P. Eells, who has been president of the former company since its organization, will be chairman of the board of directors; Wm. W. Coleman will be president; E. K. Swigart, vice-president; G. A. Morison, secretary, and Dan P. Eells, treasurer.

EDITORIAL

CONSULAR REPORTS from Hamburg bring the distressing news that a shortage in sauer kraut is impending in Germany. Let us hope that the beer and sausage supply holds out, otherwise the peace of Europe is likely to be seriously disturbed.

UNWISE friends are often a less valuable asset than ordinary adversaries. Porcupine is gradually proving its merits, and needs no exaggeration of its possibilities to make its way. Illustrated supplements of Sunday journals given over to 'write-ups' are potent aids to stock-selling schemes, but are valueless to legitimate mining.

PERSIA is in trouble with Russia, and W. Morgan Shuster, the American treasurer-general of Persia, appears to be the storm-centre. Both Great Britain and the United States have been requested to see that there is fair play in what between individuals would be called the fracas resulting from too great Russian activity in Persian affairs.

TANGLED skeins of litigation have been given a new twist by the appointment of a receiver of the Nevada-Utah Mines & Smelters Corporation by the United States District Court. Bankruptcy proceedings will be instituted, with the consent of the company, though it is not insolvent. Presumably they will at least clarify the situation somewhat and it eventually will be possible to educe some clear conception of what it is all about.

INSTITUTE MEMBERS who journeyed to Japan are finding that the heartiness and magnificence of the welcome accorded them surpasses even their expectations, which were high. Elsewhere in this issue an account of the sessions on board the *Manchuria* is given, and a member of the party writes that the Japanese engineers, not content with sending a representative to San Francisco to escort the party, also welcomed them by wireless while still many leagues from Yokohama.

DREAMS of untold wealth are pleasant, though evanescent, and on another page Mr. T. A. Rickard discusses, in his inimitable way, the possibility of the discovery of a "mountain of gold." We also present a quotation from 'Adventures in Mexico and the Rocky Mountains,' by George F. Ruxton. This fearless Englishman visited Mexico in 1846, riding horseback from Mexico City to Fort Leavenworth, unruffled by the Mexican War and hostile Indians. His account of the legend of the Black Vein of Sombrerete, courteously furnished us by Mr. Horace F. Lunt, will interest every miner, to whom reality is often so strange, that unreality allures.

APPROPRIATIONS for the work of the Bureau of Mines, for the fiscal year beginning July 1, 1912, have been recommended by Walter L. Fisher, Secretary of the Interior. They include $360,000 for investigations into the cause of mine explosions, and for general work tending to increase safety in mining operations; $135,000 for the investigation of fuel substances; $50,000 for investigations of the coals of Alaska, with reference to their mining, transportation, and utilization; and $100,000 for investigations into the treatment of ores, with special reference to the prevention of waste and the utilization of mineral resources. This is making the tail wag the dog; the last item might be multiplied by five, and the third item by ten. The purpose of the Bureau of Mines should be to aid the development of the mineral industry, not to prevent accidents and analyze fuels, with a side line of mineral investigations.

BANKING reforms continue to excite discussion, and the proposed National Reserve Association, urged by Nelson W. Aldrich, has found a friend in G. M. Reynolds, president of a Chicago bank, who has recently discussed the problems of credits and reserves. The ordinary citizen is inclined to exhibit a lack of faith in Mr. Aldrich's proposal; there is a general impression that something is the matter with our banking system, but that the correct diagnosis has been made, and that the proposed method of treatment will lead to complete recovery is, as yet, far from certain.

GOVERNMENT initiative in the operation of public service utilities is unquestionably gaining in popularity, though deprecated by many. The most recent proposal is that the Government shall build the necessary ships to operate a mail service to and from Panama and Colon. Such a plan, after the canal is opened, would do away with the necessity for illegal rebating in order to favor American shipping and is not so preposterous a suggestion as it may seem at first glance. When the American people have learned to appreciate the distinction between Socialism and socialism, progress along modern lines will be much facilitated.

Thanksgiving Day

The name awakens sentiments as varied as the individual. To the small boy it is vividly associated with roast turkey, cranberry sauce, and pumpkin pie, of sleigh rides (if the weather be propitious) to grandmother's, perhaps even skating, and, at any rate, a two days holiday from school, a delicious forerunner of the long Christmas vacation. To the business man it affords opportunity for a day in the clear bracing sunshine on the golf links, or an unusually long run in his motor car. Except to the goodly few who go to church and listen to a Thanksgiving sermon (too often deadly dull and full of little profit) few of us have any thought of the original significance of the day; our minds are too full of bright and kaleidoscopic pictures of the present to afford room for pictures of the past. But the engineer resident among alien people, who regard with curiosity this observance of a day that is a national festival, yet commemorates no great victory, no signal achievement, nor yet the natal day of a national hero, finds himself thrown back upon its origin and meaning. Though he may find much difficulty in conveying any real insight into the spirit of Thanksgiving Day to his associates, who have nothing similar in their own national customs with which to compare it, yet the American may well be proud of a lineage that boasts of ancestors who, though domiciled upon a wintry and rock-ribbed coast, surrounded by savages, cut off from intercourse with their homeland, and provided with but a scanty supply of food at the beginning of an arduous winter, yet had stout enough hearts and unyielding enough spirits to gather in solemn thankfulness to God that they were free and need bow to none other. Happily now we have outgrown the religious concepts of the Puritan forefathers, but it should be our proudest possession that their virile spirit still lives and has become a national characteristic even as their day of thanksgiving has become a natonal festival.

The State Mining Bureau

On Saturday last the appointment of Mr. W. H. Storms to the office of State Mineralogist of California was officially announced, and a matter which has dragged through many years, with but little credit to those in high places, was brought to a happy termination. Mr. Storms needs no introduction to our readers, for he has been closely identified with mining in California for almost twenty-five years, having been for some years upon the editorial staff of the *Mining and Scientific Press*. He came to California from the Black Hills in 1887, and was for six years in the service of the Mining Bureau under Messrs. W. H. Irelan and J. J. Crawford, resigning to engage in practical work in Tuolumne county. In 1899 he became editor of the *Mining and Scientific Press*, resigning a few years later to accept a special appointment to make a detailed survey of the Mother Lode region, the results of which appear in Bulletin 18 of the Bureau. Since that time he has been engaged in consulting practice as a mining engineer and geologist, having also assisted upon our editorial staff at intervals, most recently in the interval between the resignation of Mr. Courtenay De Kalb and the return of Mr. Thomas T. Read from the Orient. Mr. Storms is widely known through his contributions to the technical journals, which display equally a breadth of acquaintance with mining and geology, and a faculty of description and expression. He comes, therefore, to the office amply equipped by training and experience to perform its duties notably and well. Aside from the pleasure which the appointment gives to Mr. Storms' many friends, there arises the greater rejoicing that the State Mining Bureau has now at last opportunity to become both a credit to this great State and a useful factor in its development. It may be said without hesitation that the function of such a Bureau is service, impartial service. Political activities and private interests find no scope in its right administration; the service which it is properly called upon to perform is a highly important one, dealing as it does with one of the two foundation stones of all industry, mineral wealth and agriculture, and every citizen of California has cause for gratulation that an upright Governor, upon the recommendation of a group of public-spirited citizens of high repute and integrity, has appointed to this office a man at once able, experienced, and independent of private control. It remains now for all those who are interested in the mineral wealth of California (and their name is legion) to give the Mining Bureau and its head their loyal support, hearty co-operation, and continued, intelligent interest. There is much of present need for the Bureau to perform; further study may profitably be devoted to the Mother Lode region, the high Sierra is worthy of greater attention and study, and the petroleum resources and industry, to name but a few, can well be made the subjects of investigation and study, with profit to the commonwealth and to the individual citizen as well. There is no necessity for the reduplication of work done by the United States Geological Survey, for the purpose of effect; what is desired of the Bureau is useful service, not the 'putting up of a front.' Finally, the Bureau should play an important part in the Panama-Pacific International Exposition in 1915. And it would be fitting if, following the International Congress of Geologists' conference upon the iron ore resources of the world, at Stockholm in 1910, and the forthcoming conference upon the coal resources, this exposition in the Golden State, within the city by the Golden Gate, should be made, if possible, the occasion of an international conference upon the gold resources of the world, and the probable influence upon society of their present rate of development. In arranging for this the Bureau properly should take the initiative. Useful service is what is expected of the Bureau, and we may hope now to get it.

The Black Vein of Sombrerete

"Oh for the days of gold," sighed the old gambucino, "but that is all over now, neither gold nor silver is to be had nowadays for the picking or digging. Little bits one grubs up here and there, but the black vein, the black vein; where is it? Worked out long ago I was no older than your worship in those days, and my back was strong. Valgame madre santissima! but I could pack the ore nimbly in the mine and up the shaft. Ay, and then all worked with a will, for it was all bonanza; day after day, month after month, year after year, there we were at the same old vein; and the more we cut into it the richer it grew. Oh what silver came out of that old vein! White, rich, and heavy it was all silver, all silver. Five hundred pesos fuertes I made in one week. What a beautiful little vein was that black one!

"But your worship yawns, and my poor old head turns round when it thinks of that time. All the miners (for there were no gambucinos then) were making dollars as fast as they could, but the more they got the more they wanted, although not one of the laziest but had more than he ever before had dreamed of possessing. However, they were not satisfied, and all complained because they did not strike a richer vein as if that were possible!

"The most dissatisfied of all the miners was a little deformed man called Pepito, who did nothing but swear and curse his bad luck, although he had made enough money to last three of his lives; and the miserly style in which he lived was the byword of everybody. However, whether it was from a bitterness of spirit caused by his deformity, or from genuine badness of heart, Pepito was continually grumbling at the old vein, calling it by every opprobrious epithet which he could summon to the end of his tongue, which was enough to break the heart of any vein.

"One night—it was the fiesta of San Lorenzo—all the miners were away in the town, for they had agreed to give themselves a holiday; but Pepito took his basket and pick, and declared his intention of remaining to work: 'For,' said he, 'what time have I for holiday, when, with all my work, work, work, I only get enough out of that stony old vein to keep me in frijoles, without a taste of pulque, since—quien sabe—how long ago? Curse such a vein, say I!' Valgame dios!—this to the black vein, the black vein of Sombrerete!" apostrophized the old gambucino.

"Now your worship knows, of course (but quien sabe? for foreigners are great fools), that every mine has its metal-king, its mina-padre, to whom all the ore belongs. He is, your worship knows, not a man, nor a woman, but a spirit—and a very good one, if he is not crossed or annoyed; when the miners curse or quarrel at their work, he often cuts off the vein, or changes it to heavy lead or iron; but when they work well and hard, and bring him a good stock of cigarros, or leave him in the gallery, when they quit the mine, a little bottle of pulque or mescal, then he often sends bonanzas, and plenty of rich ore. Well, everyone said, when they hear Pepito's determination to remain alone in the mine, and after he had so foully abused the celebrated veta negra, 'Valgame! if Pepito doesn't get a visit from the mina-padre tonight, it's because he has borrowed holy water or a rosarioncito from father José, the cura of Sombrerete.'

"We were all going to work again at midnight, but the mescal was so good that none stirred from the pulqueria long after that hour. I, however, shouldered my pick and trudged up the hill to the shaft, first waking the watchman, who lay snoring at the gate of the hacienda, wrapped in his serape. I took him with me to the mouth of the shaft, that he might lower me down in the basket; and down I went. When I got to the bottom I called to Pepito, for, knowing he was working there, I had not brought a lantern, but heard nothing save the echo of my own voice, sounding hollow and loud, as it vibrated through the passages and galleries of the mine. Thinking he might be asleep, I groped my way to where he had been working the great lode in the morning, thinking to find him in that direction, and halloing as I crept, but still no answer; and when I shouted, 'Pepito, Pepito, where are you?' the echo cried jeeringly, 'Where are you?'

"At length I began to get frightened. Mines, everybody knows, are full of devils, and gnomes, and bad spirits of every kind; and here was I, at midnight, alone, and touching the 'black vein' which had been so abused. I sat down and fairly cried, when a loud shout of laughter rattled along the galleries, and broke as it was up the shaft; I trembled like quicksilver, and heavy drops of perspiration dropped from my forehead to the ground. There was another shout of laughter, and a voice cried out:

"'Come here, Mattias, come here.'

"'Where, most wonderful señor?' I asked, thinking it as well to be respectful.

"'Here, here to the black vein, the old leaden, useless vein,' cried the voice, mockingly; and I thought with horror of the abuse it had that day received.

"Half dead with fear, I crept along the gallery, and turning an abrupt angle, came upon the lode we had been working. Ave Maria purissima! what a sight met my eyes! What words can describe the glitter of the vein, now of sparkling silver, and white, as it were, with flame, but over which a black blush now and then shot, and instantaneously disappeared? I wanted not this, however, to tell me that I was looking at the endless veta negra, the scorned, abused black vein, which throbbed, miles and miles away into the earth, with virgin silver, enough to supply the world for worlds to come.

"'Ha, ha, ha!' roared the voice; 'the old leaden, useless vein. Where's the man that can eat all this silver's worth of frijolitos? Bring him here, bring him here.' And forthwith a thousand little sparkling figures jumped out of the scintillating rock, and, springing to the ground, ringing like new-coined pesos, they seized upon the body of Pepito, which I had not until now observed, who lay, blue with fear, in a corner of the gallery, and, lifting him on their shoulders, brought him in front of the silver vein. The brightness of the metal scorched his eyes, which still could not, even in his fear, resist feasting on the richness of the glittering lode.

"'What does he deserve who has thus slighted the silver king?' 'Turn him to lead, lead, lead!' answered the voice. 'Away with him, then.' The thousand sparkling silverines siezed the struggling miner. 'Not lead, not lead,' he shouted; 'anything but lead!' But they held him fast by the legs, and bore him opposite the lode.

"The rock sparkled up into a thousand times more brilliant coruscations than before, and for an instant I thought my eyes would have 'burned' with looking at the silver vein, so heavenly bright it shone. An instant after a void remained in the rock; a horrid black void. The vein had disappeared, but the rock itself was still as bright as ever, all but the black opening which yawned from out the brightness; and opposite this stood the thousand silverines, bearing the luckless gambucino.

"'Uno, dos, tres,' shouted the mine-king; and at the word 'tres'—with a hop, skip, and a jump—right into the gaping hollow sprang the thousand silverines, with the luckless miner on their shoulders, whose body, the instant that his heels disappeared into the opening, with these very eyes I saw him turned to lead. Santa Maria! then all became dark, and I fell senseless to the ground. When I recovered a little, I thought to myself, now will come my turn; but, hoping to conciliate the angry mine-king, I sought, in the bosom of my shirt, for a bottle of mescal, which I remembered I had brought with me. There was the bottle, but without a single drop of liquor. This puzzled me; but when I called to mind the fiery spectable I had just witnessed, I felt no doubt but that the liquor had been dried up in the bottle by the great heat.

"However, I was not molested, and in a short time the miners returned to their work, and, finding me pale and trembling, called me drunk and mad. We proceeded to the lode and grubbed away, but all we succeeded in picking out were a few lumps of poor lead-ore; and from that day not a dollar's worth of silver was ever drawn from the famous 'black vein of Sombrerete.'"

A Mountain of Gold

By T. A. Rickard

In a lecture recently delivered before the London School of Economics, in relation to the purchasing power of money, the lecturer, a professor, H. S. Foxwell, referred to the production of gold and its effect on commodity prices. A reviewer in the *Daily Telegraph* said that "it is conceivable that the day might come when the discovery of unlimited quarries of pure gold would compel the use of some other article for the measure of values." Indeed, those of us who are familiar with gold mining, and more especially the big bonanzas of the world, need not strain our imagination to conceive of an orebody or even a mass of gold big enough to upset international monetary standards. Many a prospector frying his bacon at the campfire and stimulated by a re-concentrated cup of coffee, must have seen visions of a golden mountain or a streak of pure gold that ran across creation as if it would never stop. Every now and then we hear of fabulous mineral discoveries, like that of Bitter Creek in June 1910, and when the irresponsible scribe in the *Daily Scream* has exhausted his vocabulary he usually ends by talking about "a mountain of gold." When the stampede to the Australian diggings was at its height in 1852, the ignorant emigrants, having heard that the gold was found in quartz, and not knowing that pervasive mineral, supposed it was 'quarts', and hence expected to gather the gold in pints and pails. This fact was related to me by E. J. Dunn, the Australian geologist, who as a boy went to the diggings at that time.

A THREE-TON MASS OF COPPER.

NATIVE SILVER FROM THE NIPISSING MINE, COBALT, ONTARIO.

Well! And why not? We may laugh at the simpleton from the farm and we may sneer (and we do) at the perfervid scribbler of the untechnical newspaper, but it is doubtful whether even that peripatetic philosopher known as the man-in-the-street could give adequate reasons for the improbability of such a golden discovery. For instance, what is the biggest mass of native copper that was ever found? Of course, it was in the Lake Superior region. It was in 1857 at the Minesota (not Minnesota) mine in the Ontonagon district. At a shallow depth there was discovered a mass of copper 46 ft. long, with a maximum thickness of 8½ ft. The mean width was 12½ ft. and the mean thickness 4 ft. The total weight actually recovered was 420 tons. Twenty men labored for 15 months to remove it from its encasing rock; they tried to do so by exploding kegs of powder, and finally extricated the copper by cutting it into fragments with chisels. The chips alone weighed 27 tons. A group of similar bodies of native copper having an aggregate weight of 600 tons was extracted from the Bay State mine forty-five years ago. The 420-ton lump was 80% pure copper and at $400 per ton was worth at that time $168,000. But a mass of pure gold weighing 420 tons is worth $252,000,000. The discovery of such a mass would add largely to the number of those sojourning in lunatic asylums and would paralyze the stock exchanges of the world for more than a few palpitating minutes.

Turning to silver mining, we shall find numerous instances of treasure trove astounding in its amplitude. 'El Cerro Rico de Potosi,' or the rich mountain of Potosi, as it was known to the Spaniards who followed Pizarro in his marauding expeditions into Peru, yielded $250,000,000 between 1545 and 1572. This came mostly from native silver. The size of the biggest mass of metal is not recorded, but the story of the original discovery is suggestive. An Indian, being in search of some lost llamas, ascended the mountain. Overtaken by the night, he made a fire and slept by the side of it. In the morning he was astonished to see that the rock under the ashes of his fire had melted and from it had flowed "a river of molten silver." Silver melts at a temperature of 960°C. Owing to the blackening caused by exposure, the silver had escaped his notice, but the heat of the fire had sufficed to release it from the encasing rock. That rivulet of metal was the beginning of a production estimated to have enriched the world by fully 1,000,000,000 ounces of silver. Without excessive exaggeration, the Cerro de Potosi can be called a mountain of silver.

The nearest parallel to Potosi is afforded by the Comstock, a lode penetrating the lower slopes of Mount Davidson, from whose depths enough silver was extracted to affect monetary legislation. The famous bonanza of the Comstock lode, in the Consolidated California and Virginia mines, was an orebody that extended from 1100 to 1800 ft. in depth; it did not reach the surface. It became productive in 1874 and for three years thereafter the average yield was $3,000,000 monthly, from which dividends of $1,080,000 were paid monthly. In 1876, John W. Mackay, who was then superintendent of the Consolidated company, took out $6,000,000 worth of ore in one month, in order to make an exhibit of bullion for the Centennial Exhibition at Philadelphia. It remains to be noted that while the yield of the Comstock is usually described as silver, it is a fact that nearly one-half of the money value of it was in gold, the ratio of gold to silver being 43 : 57. Thus the Comstock deserves to be classed under gold mines.

Coming to later days, I remember the excitement caused in Colorado in 1894 by the finding of masses of native silver in the Smuggler mine at Aspen. One mass weighed 1340 lb. and had to be cut by chisels into several pieces before it could be removed. Fully 90% of it was pure silver, so that it had a value of $17,500 at that time. Several tons of metallic silver were taken out of the same mine in the same year, but no single mass was bigger than the one mentioned.

The Kongsberg mines, in Norway, have yielded many masses of native silver, the largest recorded weighing 1537 pounds.

The Tonopah, in Nevada, is another example of concentrated richness. Discovered in August 1900 by poor men unable to conduct systematic operations on their own account, this mineral discovery was let on lease to small parties of miners, who, during the last three months of 1901, took out ore yielding over $3,000,000. To the end of 1903 this mine produced $5,576,000 in silver ore averaging $160 per ton.

Next we come to Cobalt, the greatest of modern silver discoveries. In September 1906 the stripping of the moss covering the rocky surface adjoining the Nipissing shaft led to the exposure of a vein that was 5 ft. wide of nearly pure silver. This was the celebrated No. 49 vein. A mass of metal weighing 800 lb., and 70% silver, was taken out of shallow workings. Subsequently this proved to be a part of a mass weighing 3000 lb. and worth $25,000 at 68 cents per ounce.

QUARRY OF 5-OZ. ORE, MOUNT MORGAN, 1889.

Other instances might be quoted, but these suffice. It will be observed that no mention is made of the Broken Hill, Bunker Hill & Sullivan, Mollie Gibson, Huanchaca, or other great orebodies yielding silver, because attention is only being directed to masses of nearly pure metal, not to famous deposits of complex silver-lead sulphide ores. That is another story, not pertinent to the one in hand.

Gold also has been won in lavish quantity. In 1851 the river-beds of California yielded $81,294,700, and in 1853 the shallow diggings of Victoria gave $63,000,000. This gold represented the cream skimmed from superficial deposits that had undergone concentration for geologic ages. It was picked up by inexperienced men and dug like potatoes by novices in the art of mining. We thought never to see the like again, until in 1898 the stampede to the Klondike proved that the golden age of adventure was not wholly a thing of the past. Among instances of extraordinary richness I quote the case of Dick Lowe, who cleaned up $46,000 from bedrock in 8 hours. He won $750,000 from a fractional claim 86 ft. long and the width of a narrow creek-bottom, about 50 ft. From another small claim, 40 by 60 ft., four men took out $208,000 in the form of gravel that yielded $10 per bucket. They made a profit in four months of $200,000, one-half of which went to the sole owner of the claim. One day in June 1899 no less than 20 packhorses came into Dawson from the creeks bringing gold belonging to one man, Alex Macdonald, a Nova Scotian, supposed at one time to have made $5,000,000 out of his gold mining. The biggest nugget found in the Klondike diggings weighed only 85½ ounces, worth $1,400, but much of the gold extracted was coarse, in pellets and nodules large enough to excite avarice. The mining methods were of the simplest, requiring the thawing of ground frozen by a perpetual frost and the washing (in summer) of the rich layer found on bedrock.

Nuggets have been mentioned. The biggest on record is the Welcome Stranger, found at Mount Moliagul, near Dunolly, in Victoria, in 1869. This mass of gold weighed 2280 oz., or 190 lb. Another found at Ballarat in 1858, and close to the surface, was the Welcome, which weighed 2195 oz., or 184 lb., and yielded £8376 10s. 6d. or $41,880. This nugget contained 10 lb. of quartz. The largest mass ever recovered in California is stated to have weighed 2340 oz., or 195 lb., but this was not extracted in one piece. A mass of vein gold weighing 95½ lb., constituting part of a mass weighing 145 lb., was taken out of the Monumental mine, at Sierra Buttes, California. In South Australia a nugget, called the Blanche Barkley, weighing 146 lb. and including two pounds of quartz, was found.

Another celebrated mass is the 'hundredweight of gold' found in 1851 at Hargraves, New South Wales. This was in three pieces, which originally were united, weighing 196 lb. and yielding 106 lb. of gold. Another mass of gold and quartz found at Burrandong, New South Wales, in 1858, on being pounded with a hammer, yielded 120 lb. of gold. At Hill End, in 1872, from 10 tons of quartz a clean-up of 11,424 lb., or over 5½ short tons of gold was made, indicating that the ore was more than half metallic gold. This was worth $3,300,000. One single mass out of this find weighed 630 lb. and contained gold to the value of $60,000. Most of these masses of gold contained some quartz adhering to them, so that there is every gradation, from the nugget of clean gold, 980 to 992 fine, to a mass of ore so rich in gold as to obscure the presence of quartz or other mineral impurities. This brings us to the 'pocket' mines of California, in Tuolumne and Calaveras counties more particularly. In these districts masses of free gold in quartz are found down to the water-level, at 100 to 150 ft. in depth. In 1887, at the Rathgeb mine in Calaveras county, I had the pleasure of extracting 170 oz. or $3000 worth of gold in two hours by aid only of my iron candlestick. This pocket yielded $25,000 at a cost of $200. Similar pockets have yielded as much as $500,000.

The Caledonian mine in the Thames district, New Zealand, is worthy of mention. The ore was so rich that sometimes, it is recorded, "the gold had to be cut out with a chisel." In 1871 this mine produced 10 tons of gold, that is, $6,000,000, and paid $3,000,000 in dividends. Another more famous bonanza in Australasia is the Mount Morgan, in Queensland. This mine, for the year ended November 30, 1889, produced 75,415 tons, yielding 323,542 oz. worth £1,331,484 18s. 5d., or $6,657,420, at an expenditure of £227,769 19s. 8d. The ore averaged 4 oz. 6 dwt. 4 gr. per ton; the profit was 83% of the gross; and the dividends for the year aggregated £1,100,000. At the Londonderry mine, near Coolgardie, Western Australia, in 1892, a hole not more than 2½ ft. deep, 6 ft. long, and 5 ft. wide, yielded 8000 oz. of gold, valued at over $150,000. At Kalgoorlie the Lake View Consols mine contained a bonanza from which 33,160 oz. gold, worth $660,000, was obtained in one month, namely May 1899; and during that year the same orebody gave 199,230 oz. gold, valued at $3,897,479. This was not native gold, but mainly the telluride. Another spectacular discovery was that of the Esperanza, at El Oro, Mexico, which, in 1904, after several years of disappointing development, suddenly became famous owing to the intersection of an unexpected orebody, which in November 1905 yielded $748,535, from 10,164 tons. In 1906 the output was 228,419 tons of ore worth $7,708,883 and yielding a profit of $4,644,279. In November 1905 I saw the rich stopes above the fifth level; these in places showed 5 ft. of $500 ore. The average width of the orebody was 9 ft. for a length of 680 ft., with an average yield of $50 in gold and $20 in silver per ton of ore.

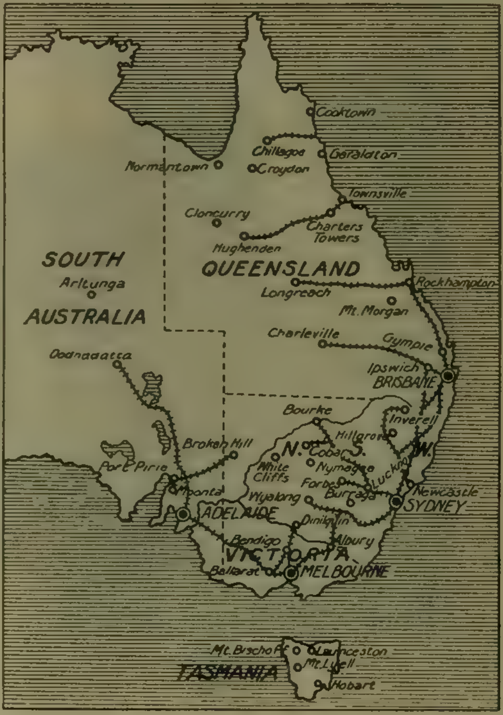
In January 1907 one carload of gold ore shipped from the Mohawk claim at Goldfield, Nevada, to the Selby smelter, near San Francisco, contained 47 tons, assaying 609 oz. of gold per ton. This ore was worth $12,230 per ton, or $6 per pound. It was shipped in sacks weighing 600 lb. each. This shipment was worth $591,637. In the Mohawk workings, at a depth of 200 ft., there was 8 in. wide of ore that assayed $250,000 per ton. The various leases in this mine yielded $50,000 per day for 106 consecutive days. The ore contained native gold and calaverite (the telluride of gold). The Mohawk became a part of the property of the Goldfield Consolidated Mines, which in 1907 yielded 31,338 tons containing gold to the value of $6,296,476.

These instances will stimulate an imagination ruminating on "a mountain of gold" or "unlimited quarries of pure gold." It must be noted, however, that the only approach to a mountain of gold is Mount Morgan, a hill about 500 ft. high, the crest of which was a gossan containing several ounces of gold per ton. This has been excavated in successive benches, so that it approximates to the "quarries" of gold ore mentioned by the writer in the *Daily Telegraph*. But the workings now are far below the foot of the hill. However, they have yielded a quantity of gold so great as to render the Mount Morgan unique in the history of mining. Since its discovery in 1886 to the end of October of the current year, this ore deposit has yielded 3,680,000 oz. of gold worth $73,000,000, besides 33,000 tons of copper. The company owning the mine has distributed $37,500,000, or £7,700,000, in dividends.

However, this is far from being "a quarry of pure gold", for the ore has averaged less than half an ounce per ton, or 1 part in 58,332, which is equivalent to 0.0017% only.

Reviewing the evidence, we find that the biggest mass of native copper ever found by man weighed 420 tons, the biggest chunk of native silver about 1½ tons, while the biggest nugget of native gold weighed only 190 lb. Thus the ratio is 190:3000:840,000. The present price of the metals is approximately as 2000:54:12.

Having passed in review the most sensational discoveries recorded as having been made by the indefatigable seekers after mineral wealth, let us now put ourselves under a cold shower of common-sense and enquire again why a mountain of gold is not likely to be found. In the first place, because none has ever been found. What has never happened may indeed happen, but it is unlikely to happen. Daily life is based on this doctrine of probability. The monetary standards of the world reflect the net result of human experience, which has gone to show that gold can be mined less lavishly than silver in the ratio of about 1 to 20. The surface of the earth has been scoured by the prospector; parts of it still remain to be investigated; many parts have been but inadequately searched. The Klondike suggests the possibility of finding new districts equal to the Californian and Australian diggings, which astounded the world sixty years ago. Cripple Creek proved how a well trodden tract may contain riches that have been overlooked, for Cripple Creek, at the foot of Pike's Peak, was on the way from Denver to Leadville, whose mineral development antedated that of Cripple Creek by 25 years. Moreover, Pike's Peak served as a beacon and a slogan to the pioneers of Colorado in 1852. Thus the face of the earth may break into a radiant smile at unexpected places. Granting this, it yet remains probable that even such unexpected discoveries, whether in virgin territory or in old mining regions, will not be unlike to, even if so rich as, those already recorded. In short, all that we know from mining experience renders it unlikely that "unlimited quarries of pure gold" or "a mountain of gold" will ever be found on this planet.



MAP OF QUEENSLAND, SHOWING MOUNT MORGAN.

The facts of experience are capable of explanation by scientific theory. Gold is a substance with difficulty soluble but readily precipitated. Hence it cannot travel far in the circulating waters that build orebodies. When thus on the move, it is easily arrested by a precipitating agent, so that the conditions favoring a large aggregate of the metal are rare. Gold is widely diffused in nature, both in the rocks and in the sea, but the largest lump ever found weighed only 190 pounds.

From a chemical point of view gold is susceptible of combination with many elements, forming compounds of more than academic interest. These include several chlorides, bromides, and iodides. Cyanides and oxides of gold, as well as sulphites and hyposulphites, play a part in metallurgy. Sulphides of gold have been artificially prepared, but they are readily decomposed. In nature, however, no chemical compounds of gold are known except the tellurides and selenides. Of these the tellurides are of great importance as constituting the characteristic enriching mineral of the ore deposits of Transylvania, Cripple Creek, Kalgoorlie, and, to a lesser degree, of Goldfield in Nevada. Sulphide of gold has been suspected in pyritic ore in which native gold could not readily be detected, but good reason exists for believing that in such cases the gold is intimately but mechanically mixed, not chemically compounded. The fact that fine crushing liberates such gold, so that it can be amalgamated, disproves its existence as a sulphide. It is possible that as a sulphide it may exist in thermal waters, for the sulphide of gold is easily soluble in hot solutions of alkaline sulphides. In the sea the gold may exist as an iodide. The least unstable of the halogen compounds is the tri-chloride, $AuCl_3$. This is the salt which is suspected to be the usual carrier of gold in lode-forming waters. But it is readily decomposed by reducing agents, such as organic matter, metals, and proto-salts. Among the metals zinc and iron, both highly electro-positive, reduce gold chloride rapidly. Ferrous sulphate is a precipitant used in chlorination works; so is charcoal. Oxidation of pyrite yields the one; vegetal remains when enclosed in the rocks furnish the other. Both are of common occurrence, especially near the earth's surface. Metallic gold is soluble in alkaline sulphides; also in ferric sulphate in the presence of a chloride; in a solution of ferric chloride and cupric chloride; and in hydrogen sulphide. Such solutions of gold are readily precipitated by numerous reagents, such as pyrite and other base-metal sulphides, by tellurides, by oxidation products such as ferrous sulphate, by carbonaceous matter generally.

A RECENT PHOTOGRAPH OF MOUNT MORGAN.

The mention of ferrous sulphate as a precipitant and of ferric sulphate as a solvent will suggest how easily the stability of a gold solution is affected and how readily the precipitated gold may resume its migration; for both these salts of iron are yielded by pyrite at successive stages of oxidation.

The nice balance of chemical equilibrium is probably potent in determining the distribution of gold within the zone of oxidation, but as regards its dispersion relative to depth it can be asserted that temperature and pressure are the dominant factors, for the increase of both favors solution, while the decrease of both promotes precipitation. That is why, in a broad geological way, ore deposits become impoverished in depth. In the approach to surface the decrease of temperature and the lowering of the pressure compel precipitation, just as in depth the opposite conditions increasingly prevail. From this we conclude that the biggest masses of gold and the richest bodies of gold ore are likely to be found within the range of shallow mining. It is fortunate for man that the substance he strives most to obtain is within the reach of his feeble efforts. He has found some of it and he may hope to find more, especially by applying skill to the winning of the larger and poorer gold-bearing lodes that persist deeply; but the farther he goes from daylight the less likely is he to find the El Dorado of his dreams. Even the dream is encompassed in a dream, for El Dorado itself is only the shadow of a myth. In 1525 a story was current among the Spanish settlements of the Caribbean coast that a tribe of Indians at the headwaters of the Amazon possessed such abundance of gold that they could afford each day to powder the body of their chieftain. Thus the legend of *el hombre dorado*, or the gilded man, became a lure to the adventurers of the Spanish main. Soon the chieftain became identified with the region over which he ruled, and the name El Dorado was passed down the centuries as the synonym for a country of untold gold. The rapacious Spaniard and the piratic Englishman scoured South America in search of it, but vainly. In later days other men, also greedy and energetic, but more experienced and more systematic, have chased the same lure, and they have called it "a mountain of gold." If it existed they would have found it ere now, for no flood has carried it away and no geological cataclysm has buried it. It never was, save in the rainbow of their imagination.

Dredging on the Gold Coast

The Ancobra Exploration & Dredging Co., Ltd., which has a dredging concession on the Ancobra river, Gold Coast Colony, West Africa, recovered, during the year ended June 30, 5120.7 oz. of gold, valued at £21,747. The dredging rights of this company extend from Prestea to the sea, a distance of seventy miles, large tracts on each bank being held in addition. S. Y. Weiss, who has had experience in California, was recently appointed manager, and reports that areas where the river has changed its course and left bare large sections of old channel would prove more profitable dredging ground than the present channel. An Empire drilling outfit has been shipped to test this ground, and if, after two or three months work, the results are satisfactory Mr. Weiss will recommend the erection of a 5-cu. ft. dredge, which should not cost over $100,000 when ready to work. The Ancobra river cuts across what is known as the Prestea quartz reef district, in which promising outcrops occur from Aufargah, on the southwest, to Broomassie on the northeast, though prospecting has been carried on over a much larger area, extending ten or twelve miles beyond Broomassie.

Mill and Cyanide Plant Records

By A. W. Allen

The necessity for the careful and accurate recording of every detail in the operations of a modern mill and cyanide plant is a point often overlooked, and carelessness in this direction, due in most cases to want of initiative in the compilation of suitable books and forms, is liable to extend to the work itself, especially where discrepancies (as, for example, between actual and assay extractions) pass unnoticed.

I propose to deal with a system of arranging the records in connection with the treatment of the ore and the recovery of precious metal, and append a number of forms (accompanied by short explanations where the latter have seemed necessary), which may prove of use as suggestions for other, and possibly more suitable, forms, complying with local conditions.

The Assay of Gold-Bearing Cyanide Solutions by Electrolysis

By C. CRICHTON

The estimation of metals by means of electrolytic deposition is in general use in most laboratories, the only difference between the determination of gold and, say, nickel or copper, by this means being that in the latter case the increase in weight on a platinum cathode is noted, and in the former a lead cathode is used and the gold obtained by cupellation. The apparatus at present in use at a well known assay office consists of four oblong frames, 2 ft. 10 in. by 3 by 6 in., connected in parallel, and each holding eight beakers. The frames or boxes are provided with two copper rods.

The anodes consist of ordinary $^5/_{16}$-in. arc-lamp carbons, and are held in position in the centre of each beaker by means of clamps fitted to a horizontal copper bar which runs parallel to and 6 in. above the top of the box. By means of a slot and thumb screw the anode connection rod is attached to two uprights fixed at either end of the box, so that each section of eight carbons may be either lifted clear of the beakers or lowered, as required, in one movement. The cathode connection-rod runs along the front side of the frame, slightly above the top, and about 2 in. from it; at suitable intervals along the rod are soldered eight single flexible insulated wires, forming a connection for the lead cathodes.

The cathodes are made from ordinary assay lead foil, a suitable length being 9 in., and as the foil is usually obtained in strips 36 in. long, a good quantity of the necessary lengths can be obtained in a short time by cutting the foil into four equal portions. About a dozen of the lengths are placed together and V shaped pieces cut out from along the edge intended for the bottom of the cathode, so as to allow better circulation of the ions through the solution. Arrangement has to be made for connecting with the flexible wire from the cathode rod; for this purpose a strip about $^1/_4$ in. broad is all but severed from one end of the foil and folded over, forming a terminal. The two ends of the lead are now brought together and connected by folding the edges; to ensure a smooth surface and circular shape a glass bottle having a slightly smaller diameter than the inside of the beakers in use will be found to be convenient for this operation. Very little time is occupied in making the cathodes; a native can, during a few hours, make a sufficient number for 200 or 300 assays.

The necessary current for the deposition of the gold in solution onto the cathode is obtained from three 2-volt accumulator cells, which being connected in series give a terminal pressure of just over six volts. The current varies, of course, with the resistance offered by the solution through which it passes, and the stronger the solution in KCN the greater will be the amperage. For example, a solution having a strength of 0.3% KCN passes 0.1 of an ampere, and a slime solution (0.02% KCN) will take a current of about 0.04 ampere. The accumulators are charged from a direct-current lighting circuit through a suitable lamp resistance, and connection can be effected between the lighting circuit and accumulators, or accumulators and electrolytic apparatus, as desired, by means of two-way switches. Little remains to be said, except that perhaps a few details regarding operation may be of interest. The usual number of solutions assayed each day is 22, which are sent up in marked bottles from the cyanide works at 6 a.m. Portions of 10 A. T. each are at once measured out from each bottle and placed in the beakers belonging to the apparatus, which are prepared the previous evening, so that as soon as connection is made no further attention is required. The time required for the complete deposition of the gold is four hours, after which period the carbons are removed clear of the beakers, the current is switched off, and the lead cathodes disconnected and removed to a hot plate to dry. When dry these are folded into a small compass and cupelled with a little silver, parted, and weighed, the results being reported to the cyanide works manager by 11 a.m. Although from start to finish this process occupies about five hours, only a few minutes are expended in actual personal attention, and the measuring out of the quantities of solution can be done either by the cyanide works shiftman, or in other cases by the reduction works sampler. I might mention that if 20 A. T. of solution is required for use instead of 10 A. T., the same time only is necessary for the complete deposition of the gold on the cathodes.

Precautions should be taken against having the carbon anodes in contact with gold-bearing solution when no current is passing through; negligence in this particular results in gold being precipitated on the anode. In the event of a solution offering too great a resistance to the current, the addition of a small quantity of KCN will remedy this, and accelerate the deposition of gold. It has also been found advantageous to add a little ammonia to solutions which deposit salts.—*Jour. Chem., Met. & Min. Soc., S. A.*

Cost Analysis

By G. L. WATSON

The efficiency of any system of cost-analysis depends, in the first place, on the accuracy of cost records. To serve the purpose well, these must be clear and reliable, and the conditions of the work concisely explained. Furthermore, the items of cost should be kept in accordance with some uniform system so that records for different jobs may be compared intelligently and used advantageously in the analysis of costs for future estimates.

One thing has always struck me very forcibly, and that is, no matter how good a cost-keeping system may be, I have yet to find an individual or a concern who has it kept up as it should be. To get costs and to make the proper distribution on the records should be the duty of one man alone. If this man is shown what to do and how to do it, where and what charges to make, and is on the job all the time, keeping a journal and photographs as well, then at the end of a job these records are worth something, but ordinarily the timekeeper simply makes the easiest distribution he can and gives no details. On one job not long ago, reports came to me for one week on a certain kind of work showing that, apparently, the same work had been done four times, according to the plans. I made an investigation and found that the clerk had simply charged up the easiest unit to figure out.—*Jour. Amer. Soc. Eng. Contractors.*

Principles of Gravel Mining

By William H. Storms

There are certain fundamental principles that underlie successful placer mining, whether it be by the simple method of shoveling directly from the pit into the sluices; by what is known as ground-sluicing; or by hydraulicking. These fundamental considerations are: (1) the grade of the stream, or the ground where the placer is situated; (2) the volume of water available for mining; and (3) in the case of hydraulicking, the pressure (head) that can be secured. The duty of a miners' inch of water is a variable quantity, but, obviously, in the same bed of gravel, whether it be loose and free-washing, or tight, due to admixture of clay and iron, the amount of gravel that can be moved within a specified time by a miners' inch of water must depend wholly upon the volume of water and head available, and, to a great extent, upon the grade that can be secered to carry away the tailing. In California mines the duty of the miners' inch has been found to range, under widely differing conditions, from 1 cu. yd., where the gravel was cemented with clay and iron, to as high as 36 cu. yd. where the gravel was free-washing and contained few boulders. It may be said of a bank of gravel of this description that it seldom carries much gold, though this does not necessarily imply that the tight cemented gravel is invariably rich, for such is not the case.

In simple sluicing and in ground-sluicing operations, the volume of water and the grade are the most essential considerations; in hydraulicking, the volume of water and head obtainable are the main features, for, lacking the necessary grade, this latter may be artificially created by employing what is known as the hydraulic gravel-elevator. Numerous attempts have been made in various mining regions to also create head for hydraulicking by pumping, even for the operation of elevators, but, while these installations have generally proved successful, as viewed from the standpoint of the engineer, they have in most instances been failures financially. C. W. Purington[*] states that out of nine plants visited by him in Alaska and in the neighboring British territory, at which pumping to secure head for hydraulic mining was in progress, not one of them was making expenses. It has been demonstrated in some instances that where this method has failed to produce satisfactory economic results, other methods, such as mechanical shovels operated by derricks, or by drag-ropes, and even horse-scrapers, have proved successful. In a general way it may be said that successful hydraulic mining requires a head of water of at least 200 ft., and a grade of not less than 200 ft. per mile must be available to carry the tailing away from sluices, or it will bank up and soon obstruct further operations.

On looking at the vast hydraulic pits made in the early years of hydraulic mining in California, at such places as Dutch Flat, Gold Run, Iowa Hill, Columbia Hill, and elsewhere, it is clearly evident that the monitors of the early miners caused mountains of gravel to crumble down and disappear before the resistless impact of their streams. The material which formed these gravel banks often had a width of from a hundred yards to over a mile, and was a few feet to over 600 ft. in thickness. In a great many instances these ancient streams, in beds of which the gravel lay, lacked the necessary grade for the water employed in hydraulicking to carry away the enormous quantity of tailing, but in every case a canyon of the more recent drainage of the region was near at hand, and to these bedrock-drains, and often tunnels, were cut for the passage of the débris, consequently the difficulty of insufficient grade was easily overcome. In a country of low topographic relief, this simple and effective method of disposing of tailing from gravel mines is not available, and then the hydraulic elevator, or some other mechanical means, must be resorted to in order to secure the necessary grade, both for the washing sluices and for disposal of tailing.

Sluices should have a grade of 6 in. to the 12 ft. length of box, or an excess of water will be required to move the gravel. However, whatever the grade, the amount of water should be such that it will just cover the largest rocks going through the sluice. When this is the case the best work is being done. Generally the grade given to each 12-ft. box is 8 to 12 in., if that much fall is available, and sometimes even more than 12 in. is desirable. Steep grades facilitate the disposal of material going through the sluice, and are advisable where the quantity of water is somewhat limited. Sluices should be wide, rather than narrow and deep, and, as previously stated, the depth of water should be just sufficient to cover the largest rocks passing through. Narrow sluices are much more likely to jam than wide ones. Where shoveling into the boxes is the method of mining, a grade of 5 or 6 in. to the 12-ft. box, with a flow of 40 in. (60 cu. ft. per minute) will wash 6 to 7 cu. yd. of gravel per hour. As a general rule there should be only sufficient water running through the boxes to move the largest stones, and to keep the sand from packing, no matter what the grade.

Where gravel-elevators are employed it is the usual practice of experienced miners to employ about two-thirds of the available water in the elevator, the remaining one-third being used by the giant in washing the gravel to the pit at the foot of the elevator. It is also good practice to use just as little water as possible in operating with the hydraulic-elevator, or, in other words, endeavor to get all the gravel possible to the pit, that the elevator may be worked to its fullest capacity. Nearly all miners who have used the elevator say it will handle more gravel than they have been able to send to it. It has been found that the hydraulic elevator will, under favorable conditions, successfully lift gravel to a height equal to 20% of the total head of the stream of water used in the elevator. However, a lift of 10% is much more common. Where there is a large quantity of water seeping into the pit, which accumulates at the foot of the elevator and thus lessens efficiency, it is generally feasible to lift this surplus water from the pit by means of an independent elevator. Such an elevator, in use in Alaska, according to C. W. Purington, lifted 80 in. of water to a height of 26 ft. by employing 70 in. of water under a head of 100 ft. delivered through an 8-in. pipe, choked to a 2-in. nozzle, the lift-pipe having a 4-in. throat. Ditches usually have a grade of 7½ to 18 ft. per mile. To secure the greatest volume of flow through a ditch it should be from 1¾ to 2¼ times as wide on the bottom as the depth of the water at the sides. This also applies to flumes.

As gold has a very high specific gravity it is usually found in the deepest part of a stream that has a moderate grade, but where the current is swift the gold is usually found on the bars, as the inside, or shorter side of the bends are called. Since gold has so high a density many think, very naturally, that where potholes exists these should be rich in the accumulated gold, which once having entered cannot escape. Those who have mined these potholes have almost invariably been disappointed, finding no gold. Potholes are formed by boulders lodging in a depression in the bedrock, generally at the side of the stream, and are usually uncovered in stages of low water. In time the rocking of the boulders upon the sand that settles in the depression gradually wears the hole deeper and deeper, until it becomes a pothole. Any gold that chances to drop into one of these holes will be literally worn out by the attrition of sand and boulders that are swirled about by the water rushing over the hole, and by the time the stage of low water arrives the gold has disappeared. Crevices in bedrock may be, and frequently are, rich in gold, but potholes rarely, if ever, are found to be so.

---

[*] Bulletin 263, U. S. Geol. Survey.

The British Home Office has issued a report in which it is stated that the number of persons employed in the mines and quarries of the world in 1909 was 6,000,000, of whom 1,250,000 were employed in the British Isles and 1,000,000 in other parts of the British Empire. The total value of the mineral production is estimated at $4,209,522,500, the value of the coal output being $1,946,600,000.

Concrete Shaft-Stringers

By A. N. Wold

Owing to the scarcity of timber and the heavy cost of transportation, many of the large mining companies in the Lake Superior district have of late years been experimenting with reinforced concrete as a suitable substitute. The experimental stage, as far as concrete shaft-stringers are concerned, is now past and it is a well established fact that they are far superior to the timber stringers. The chief claim to superiority lies in their permanence. Barring accidents, such as derailing of the skip, they are everlasting; and even in such cases the repairs are easily made and at a comparatively low cost, without delaying hoisting to any great extent.

One of the mines at the northern end of the peninsula is now experimenting with the so-called reinforced concrete mine timbers, square-sets, studdles, caps, and even lagging. From all indications they promise to be successful, in which event a revolution of the present mine-supporting methods of the district may be expected. If this substitute for timber can be made cheap enough the practice of leaving pillars of ore may be abandoned and most of this ore, which is now either lost or held up indefinitely, may possibly be taken out at a profit. The accompanying sketches show the different methods now in use of laying concrete shaft-stringers.

Where the dip of the shaft is not greater than about 50°, the tendency to slip is overcome by the irregularity of the rock in the foot-wall of the shaft, but with a greater angle of dip it is necessary to anchor the stringer to the foot. Fig. 1 is a side view of a section of a concrete stringer used in a steep shaft, with a dip of about 70°. The parts A, B, and C constitute the Anchors, which are placed at intervals of about 25 ft. (See detail sketch, Fig. 4.) This interval, of course, depends upon the dip of the shaft and upon the weight of the load carried. The rails are fastened to the stringer by means of clamps L (Fig. 2) and bolts F, which open into the hand-holes H. These hand-holes are formed by galvanized iron boxes, open at both ends, and are held in place, during the process of laying the stringer, by the wooden blocks O, which are nailed to the form boards P. These in turn are supported by the temporary 2 by 6-in. pieces G (Fig. 1). The forms for these hand-holes may be built of wood instead of galvanized iron. The bolts pass through galvanized iron tubes, which are placed over the openings in the boxes. A rectangular washer, N, is used at the lower end of the bolts in the hand-holes. These rail-clamps are placed about 3 ft. apart. The tendency of the rails to slip is overcome by anchors, composed of the pieces D and E, placed about 3 ft. from the ends of each rail. (See detail sketch, Fig. 5.)

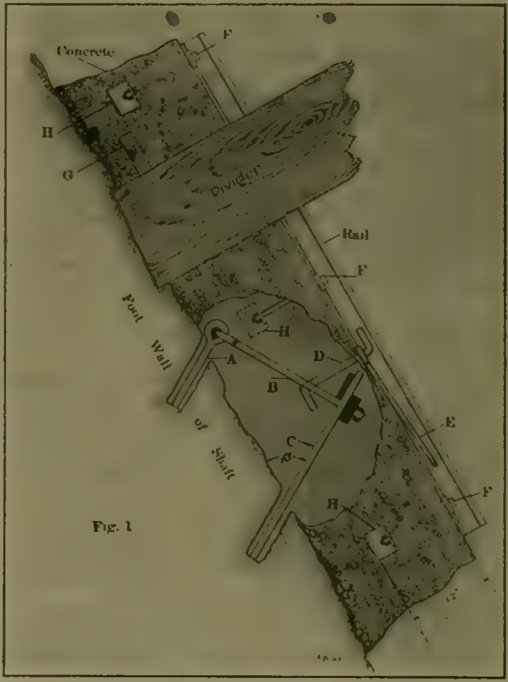

Fig. 1.

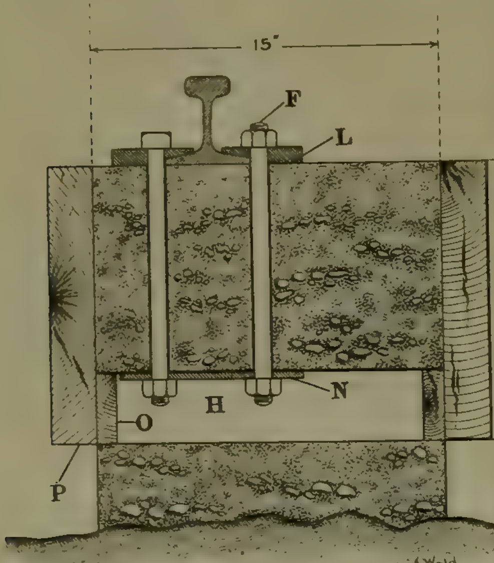
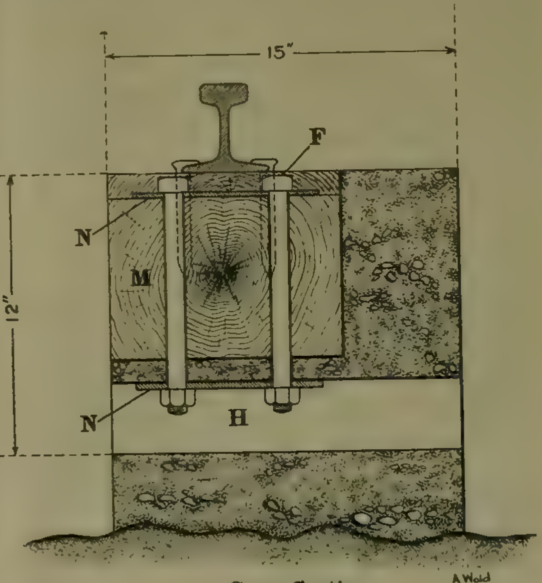


Cross Section

Fig. 2



Cross Section

Fig. 3

Another method combines wooden and concrete stringers, as in Fig. 3. An 8 by 10-in. fir timber, M, is tied to the concrete foundation by means of the bolts used to fasten the rails in the first case. The interval between the bolts is greater, however. The bolts F are countersunk on top of the timbers, using the rectangular washer N. The washer, N, in the hand-hole, H, is made wide, so that it has a larger bearing-surface on the concrete. The rails are spiked to the wooden stringers, the flanges being notched for the spikes, to prevent slipping. Fig. 6 shows a method used in a shaft having a dip of about 45°. At first the rails were laid directly on the concrete, but it was found that the jar and vibration was so great as to actually crystallize the steel axles of the skip, often causing them to snap off.

The normal (to the track) component of the weight of the loaded skip increases as the dip decreases. To remedy this difficulty blocks of wood, B, 2 by 4 by 12 in., are set in the concrete every 3 ft. and projected ½ in. above the surface of the stringers. By placing the rails on these blocks all the jar is taken up by them. A different method of fastening the rails can also be used. The bolts are set in diagonally and form a claw which grips the rail firmly. The recess, C, in the concrete corresponds to the hand holes in the preceding cases. These bolts are spaced 6 ft. apart. These methods, or their combinations, have proved to be entirely satisfactory in all cases.

Treatment of Lead-Zinc Sulphides

London Correspondence

During the last three or four years much has been heard in a mysterious way of a new process that would completely revolutionize the metallurgy of zinc-lead sulphides. The process sprang originally from a proposal made by Sulman & Picard for the leaching of the roasted ore by means of sulphurous acid direct, thus obviating the great expense of sulphuric acid manufacture. The practical application of the idea bristles with all sorts of technical difficulties, and the number of patents issued covering modifications is legion. Sulman & Picard lost interest in it, and further work was done by Hommel & Durrant. The presiding genius, however, is Martin Fradd. Works have been acquired at Swansea, and the patent rights in Tasmania have been acquired by people interested in Mount Read and other complex ores. As far as can be gathered, the process consists of roasting the ore, and passing the sulphurous gases through pulp consisting of roasted ore and water. In this way the soluble bisulphite, $ZnH_2(SO_3)_2$, is formed. The resulting solution is taken to vats where insoluble monosulphite, $ZnSO_3$, is precipitated. This monosulphite when heated is dissociated into zinc oxide and sulphurous acid. The zinc oxide is free from lead and is a desirable raw material for the zinc distiller. The remaining pulp, after the removal of the bisulphide, can be treated for lead or copper in any ordinary way, according to its composition. The process gets along so slowly that its final success is considered problematical by skeptics. Anyhow, the owners and exploiters of the process have never taken the technical public into its confidence, so the average scientist knows nothing of the difficulties to be overcome. The process would be of no use in places where the ejection of sulphurous fumes is prohibited, for the final part of the operations involves the roasting of the monosulphite. It is no use saying that this sulphurous acid can be used over again, for the acid is being continually generated at the roasters. If the eventual sulphurous acid has to be neutralized, why not neutralize the gases coming from the first roast?

Time in Tunnel Driving

The time consumed in one cycle of operations in driving the Laramie tunnel was as shown below, the figures being given in a paper read by D. W. Brunton before the American Institute of Mining Engineers:

Opration.	Hr.	Min.		Hr.	Min.
Exhausting smoke at face		10	to		12
Picking down roof and sides		5	"		10
Jacking cross-bar in place		6	"		8
Attaching drills, making hose and water connections		5	"		15
Drilling from top set-up	3	0	"	4	15
Dropping bar to lower position		15	"		20
Drilling from lower set-up	1	0	"	1	15
Removing drills, cross-bar, etc.		15	"		20
Blowing out holes, loading, and firing		20	"		25
Ignition to explosion of last hole		8	"		8
Total	5	24	"	7	28

The Argentine Government has resolved to construct moles at Comodoro Rivadavia for the discharge of materials to be used in the exploitation of its petroleum resources.

The Mining Engineers in Japan

EDITORIAL CORRESPONDENCE

The party of engineers and guests that sailed for Japan following the meeting of the American Institute of Mining Engineers in San Francisco last month had a pleasant journey across the Pacific. Forming a majority of the cabin passengers on the *Manchuria*, they were actively represented in all the activities on board ship. It is difficult to say whether more renown came to the party through Dr. Raymond's Sunday sermons to the missionaries, C. L. Goodale's prowess at shuffle-board, or W. L. Saunders' impersonation of a life saver at the masque ball. In everything that took place the engineers were well represented. Following a busy but pleasant day at Honolulu October 23, a series of lectures and technical sessions, presided over by J. W. Richards, vice-president of the Institute, was organized. Interspersed with the technical sessions were others at which Reiji Kanda, C. L. Goodale, and other passengers talked of Japan, Hawaii, and China in popular vein.

The first technical session was held October 25, when D. W. Brunton read a most interesting paper on the Laramie tunnel recently completed under his supervision forty miles west of Fort Collins, Colorado. The tunnel was remarkable for the speed at which it was driven, especially in view of the fact that it was but 11,306 ft. long, and the work occupied but 18 months, so that the increased efficiency due to continuous operation of a trained force was not fully realized. In driving the tunnel standard equipment was used, for the sake of salvage, despite the fact that the cars were higher and the gauge narrower than would have been preferred. The greatest footage in one month from one heading was 653, made in March 1911. From March 1 to 8 an average of 24 ft. per day was maintained, and for four successive days the breast was advanced 28 ft. The cross-section was larger than usual, 7½ by 9½ ft. (actually driven 8 by 10 ft. to avoid trimming) and required 18 holes, but the shape was oval so that the corners were not cut out. The holes were drilled to an average depth of 7½ ft., and shot with Repano 80% gelatine exploded by means of fuse. The bonus system of payment was adopted and is regarded by Mr. Brunton as an important factor in obtaining the high speed noted. Another feature was the use of Leyner drills, especially a new type, known as Model 8, developed in part in the course of the work. Operating with air at high pressure, on a clean face of rock, with a cool bit, these drills made remarkable speed. While costs were not given, the enumeration of men and wages, as well as quantities of powder and supplies used, indicate that in this particular as well as in speed the work compared favorably with that done elsewhere.

The paper was discussed by W. L. Saunders, H. F. Bain, and others. Mr. Saunders pointed out that despite the good work done in America, European practice was still ahead of that in the United States. This he attributed in large part to the longer tunnels driven abroad, which permitted the more prolonged training of an individual crew. The drilling of shorter holes and use of a drill-carriage were also considered important, but at the present rate of improvement in America he expected to see practice here overtake if not surpass that of Europe. In the further general discussion of the paper it was shown that otherwise excessive use of powder in a tunnel is economical because of the resulting pulverization of the rock and increased speed in clearing away the débris. In large stopes and quarries where 'bulldozing' is possible and speed less important it is proper to economize in the use of powder.

At the second technical session of the Institute, held October 30, Will L. Clark discussed the need of a thorough revision of the United States mining laws. He introduced the subject by reading from the report of the committee of the American Mining Congress on 'General Revision of Mineral Land Laws,' presented at Los Angeles last fall. This committee consisted of E. B. Kirby, Will L. Clark, F. G. Tyrrell, W. H. Dickson, and M. Baumgartner, and reported in favor of asking Congress to appoint a commission charged with the duty of holding public hearings in the various mining districts and formulating a comprehensive mining law. The committee stated that "in spite of the good intentions of the makers of these early acts, the fact remains that our mineral land laws are imperfect and obsolete, and not sufficient for our present conditions, and that many of the existing provisions tend to unsettle rights to discovery, to discourage investments, and to retard development of latent resources." The extralateral right, defective regulations relating to discovery and locating, obscurity of tunnel rights, locations of an unlimited number of claims by one person, abandonment and relocation by the same individual, location by proxy, uncertainties of placer location, and conflicts between placer and lode location were all mentioned as causing vexatious litigation. It was suggested by Mr. Clark that the present was an opportune time to secure something better than patch-work revision, in view of the interest in 'conservation' legislation, the leasing system, Alaskan, and other matters. The report of the committee, he said, had already been sent to every senator and representative, as well as to the governors of the public-land States, and many promises of support had been secured. He quoted approvingly a suggestion made some time since by R. W. Raymond that apex and extralateral rights be abandoned, vertical side lines adopted, and the public lands be promptly surveyed and classified. The fact that by purchase and private contract vertical boundaries had come to be the rule in the large mining camps was mentioned as an instance of the mining men working toward the simpler system in spite of the law.

Mr. Clark also presented the report made by another committee, consisting of W. R. Ingalls, J. Parke Channing, James Douglas, J. R. Finlay, and John Hays Hammond, in which was formulated a draft for a law governing mine inspection and designed to further the movement toward a uniform system among the States. Finally Mr. Clark submitted the first draft of a law regulating metalliferous mining in Arizona and prepared by the Arizona Mining Code Commission, of which he is a member. These various papers led to a lively discussion, participated in by R. W. Raymond, W. L. Saunders, D. W. Brunton, H. F. Bain, F. H. Proske, R. W. Hunt, and closed by Mr. Clark. Dr. Raymond pointed out many of the difficulties of work under the present mining law, instancing that the apex was first regarded as a point, then a line, and now an area. The law of the apex operates in cases to wipe out discovery rights, and the whole law was characterized as one involving mathematical impossibilities, stated in language that is grammatically impossible, and requiring physical impossibilities. He deprecated any increase in Governmental activity and urged as evidence of beaurocratic inefficiency that even now the public lands are largely unsurveyed and unclassified. Later, in discussing safety in mining, he condemned the lack of discipline among miners, and imputed this to the growth of unionism among the men. Mr. Saunders pointed out that the unions, like the poor, "would be always with us," and stated that for one abuse on their part there had been five by the operators. He urged the necessity of sticking to the main point and making progress without wasting time on unavoidable conditions. He pointed out the necessity for legal action to increase safety in mining, and instanced the dangers incident to 'blasting off the solid' in coal mines, and to silicious dust in metal mines. He paid a tribute to the excellent work lately begun by the U. S. Bureau of Mines. Mr. Bain pointed out that the classification of the public lands was the legal function of the U. S. Geological Survey and suggested that the speed of the work was largely a function of amount of money appropriated. Mr. Proske suggested that the Administration at Washington seemed already committed to urging a leasing system, at least as regards oil, coal, and phosphate lands, and urged the necessity of prompt action if this change was not approved by mining men. For himself he considered the proposed system pernicious. Mr. Hunt urged the importance of the commission suggested by Mr. Clark and expressed his belief that if the matter were properly presented at Washington the appointment would be made. Mr. Clark closed by asking the assistance of the members of the Institute as individuals, since the rules forbade any official action.

At the third technical session, held November 1, R. W. Hunt presiding, J. W. Richards discussed the 'Electrochemical Industries of Sweden and Norway,' giving the results of his studies there during the past summer. These countries, he said, show striking similarities to Canada and Alaska, Sweden resembling Ontario and Quebec, and Norway being like British Columbia and Alaska. Neither Norway nor Sweden has any coal supply except the mines at Spitzbergen, but both have abundant water-power. That of Sweden comes from large rivers with slight fall, while that of Norway is derived from shorter and smaller rivers with high head. The development of these powers has become a matter of first importance. The Swedish iron industry has been built up on the basis of abundant charcoal, but the supply is now scant and wood is more valuable for making pulp. The price of charcoal has doubled in five years. English coke is being substituted to some extent, but this is temporary, and electric furnaces are being rapidly built. These use one-third ton of charcoal per ton of pig, as against an old ratio of 1 to 1. In Norway the high head enables power to be developed at a cost of $25 to $30 per horse-power for first cost. In Sweden the cost is higher, $40 to $80 usually, but occasionally as high as $100. In Norway power has been developed at a cost as low as $22 and rarely costs over $35. The annual charge for operation, including interest and depreciation, is $7 to $11 per year in Sweden and $4 to $7 in Norway. Water-powers in both countries belong to the Government and are merely leased to operating companies for terms of 50 to 70 years, with the requirement that the whole property, including plant, shall revert to the Government at the end of the lease. The powers are being rapidly developed, in the main by local capital.

Electrochemical industries need cheap raw material, cheap transportation, good labor, and capital. These are all available in Sweden and Norway. The former has the advantage in possessing iron ore, more labor, and more capital. Norway has the cheaper power and better transportation, since the waterfalls are generally at the head of deep fjords. Numerous new industries are being established and old ones revived. Among the new industries are those in which nitrogen is taken from the air to form nitric acid, nitrites, and nitrates. In the heat of an electric furnace the nitrogen and oxygen combine, and if the product can be cooled quickly a small but commercially profitable amount remains in combination. In central Norway 80,000 hp. is used at one point in industries based on this reaction, and by the end of next year probably 300,000 hp. and works representing an investment of $15,000,000 will be employed. The products are sodium nitrate, nitric acid, and 'nitro-lim' or 'Norwegian saltpeter.' The last is used for making fertilizer. These works are affiliated with important German companies. Another important industry is that of the manufacture of calcium carbide. This was first made in the United States, but the industry early obtained a foothold in Norway. The Alby United Carbide Factories, Ltd., at Odde, uses 20,000 hp. in making 30,000 tons per year. About one-half of this is used for generating acetylene and the remainder goes into calcium cyanamide, which with acid obtained from roasting mixed sulphide ores is transposed into ammonium sulphate and used for fertilizer. Other carbide works are in operation in Sweden.

Electrochemical processes are also used in the production of numerous metals. At Vadeim nearly all the sodium used in Europe is made, 400 hp. being used. The plant will be doubled this year and as much more added in 1911. There are also two aluminum works. The Anglo-Norwegian Aluminum Co., at Vigeland, uses 12,000 hp. and the British Aluminum Co., at Stangfjord, 2500 hp. Since, however, aluminum abroad only brings 15c. per pound, the industry is not flourishing. Nickel is produced at Christiansand from an ore containing 1.2% Cu and 1.8 Ni. This is made into a matte containing 10% Cu and Ni, and then refined electrolytically. The metals are recovered as sheets on lead plates and are sold in Germany. Zinc reduction is a field of great promise, and after spending $100,000 in experimental work on mixed sulphides the Swedes may fairly claim to have solved the problems involved. Work is now conducted at Halfslund, Tyssaa, Tyssedal, and Hardanger. DeLaval furnaces are used, and one 7000-hp. plant is being built. Near Odde, where 125,000 hp. is available at an annual charge of $8.10 per horse-power, 20,000 is to be used in treating zinc ores, 10,000 in making steel, and 40,000 in making cyanamides. The sulphide ores are first roasted to make acid for converting the cyanamide into ammonium sulphate. Australian ores are so far used mainly. Ferro alloys, such as ferro-silicon and ferro-chrome are made, but low prices prevent expansion of the industries.

The most striking and significant change produced by the introduction of electro-chemical processes has been in the iron and steel industries. It cost nearly $250,000 to develop the processes, but now plants are being put into operation as fast as they can be built. On the basis of a six months' test with a furnace using 700 hp., it was found that pig iron could be made at a cost of $1.50 per ton less than in ordinary blast-furnaces in Sweden. A large furnace, which ran from November 1910 to April 1911, used electrodes to the extent of but 5% of the weight of iron. In one week 1350 kw. produced 131 tons of iron, and it is found that 5 tons of pig iron can be made per kilowatt-year. The cost for power is $2 per ton of iron. Probably even better results will be realized. There are now four furnaces in Sweden that will be operating by the end of the year and six others are building. It is feasible in the electric furnace to make pig iron containing as little as 1.2% carbon, and nearly free from sulphur, and phosphorus. This is really a 'pig steel,' and permits cheap manufacture of steel billets. In steel-making, proper, the first development was the making of an equivalent of crucible steel. In Sheffield it cost $25 per ton to perform the operation, while in Norway the cost is $3. It can also be made in Norway with inferior material. Steel furnaces are accordingly going up all along the coast. At one the power contract calls for $6.75 per horse-power year for the first 1500 hp., and $5.40 thereafter. This covers cost of power on the turbine shaft; the steel company must furnish the electrical machinery. It is found that coal at $6 per ton is equal to power at $6 per year in making the initial melt, but that the electric furnace holds the melted material cheaper. Open-hearth furnaces are therefore used for melting the scrap from which the steel is made. It is then refined in the electric furnace. At Arendal it is estimated that steel billets cost $29.16 per ton, using 12,000 hp. to produce 14,500 tons per year.

This paper by Mr. Richards provoked a lively discussion centring mainly on the low cost of power. No very satisfactory explanation was given as to why there should be the very great difference between power costs in Norway and the United States, though many factors evidently enter into the problems.

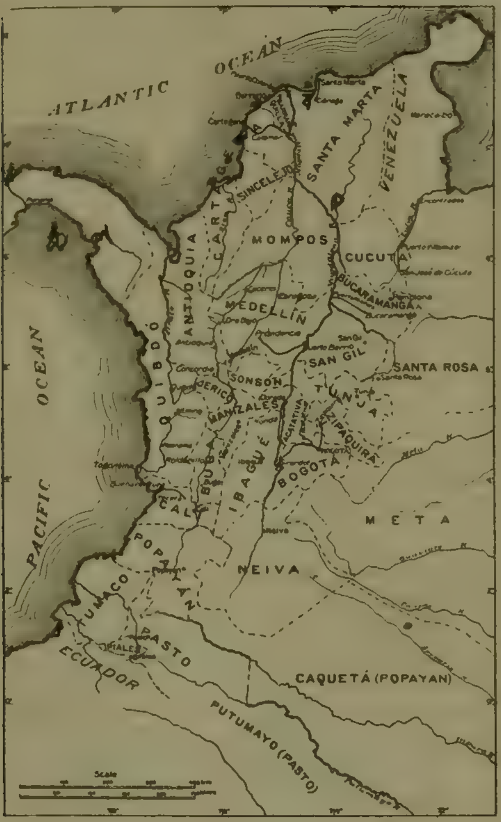
At the final session on board the *Manchuria*, Reiji Kanda discussed the 'Mines, Minerals, and Volcanoes of Japan,' giving a general outline account of the geology of the various islands and the distribution and character of the mineral deposits. This was well calculated to be of great service to the visiting engineers.

WASHINGTON'S production of lead in 1910, although small, was the largest which the State has had in recent years. It amounted to 661 tons, as against 144 tons in 1909. Practically all of this output came from Stevens county and was derived chiefly from the Northport district, with a smaller quantity from the Bossburg district. The lead ore of the Northport district is non-argentiferous and was shipped to the soft-lead smelters of the Mississippi Valley. The Jupiter mine was the principal producer.

Prospecting in Colombia

By A Peripatetic Engineer

Cali, in the central cordillera of Columbia, is reached about two months after leaving San Francisco. The delay is chiefly due to the five weeks' trip down to Panama on a Pacific Mail boat, which goes even to the length of waiting in some ports to pick up cargo coming down by train in two or three days' time. This will soon be a thing of the past on that route. For about three months I was opening, for the owners, a coal prospect about two miles northwest of Cali and uncovered a 5-ft. seam of coking coal. It lies almost vertically and should have about a thousand feet of backs from the level of the Cali river, but from the lay of the surrounding country I should say it will be found to be much faulted. I know of three other exposures of coal in that neighborhood which ought to be valuable when the railroad gets through. The track extends now to a point about six miles out of Caldas, a little town which is the present terminus of traffic. In that six miles there are seven or eight tunnels, all short, owing to the numerous deeply cut *quebradas* running down from the main ridge. They say they will get the railroad into Cali in two years time. They had considerable trouble in driving and keeping open those tunnels in the heavy clayey decomposed rock. After British Columbia, where fresh solid rock is found under 2 or 3 ft. of soil, the amount of decomposition here comes as a surprise. Without exception, every prospect I have seen has been in the bottom of a *quebrada*. Everywhere else is covered up deep with soil and decayed vegetation. After about four months in Cali, my partner got 'fed up' with the country and people, and returned to British Columbia. A good-enough partner, but too cultivated and refined for a mining life; he couldn't get along without music and books.



MAP OF COLOMBIA.

Then I went to a district called El Quindo, in the central range, two days' ride from Cartago, and made a few assays and reports for local companies, and examined prospects on my own account. At this I found I could hardly make expenses. I arrived at the tail of a local mining boom and found they had already put wooden mills up on all the veins that showed a trace of gold at the surface, without doing any previous development, and were reaping the natural consequences. That is one of the greatest hindrances to a man like myself, looking for a small property to work. The Colombians have unbounded mining optimism, and rush in where angels fear to tread; put up a wooden mill if the rock pans a few colors, and trust to luck. Of course they may open up something which will prove profitable, but in the majority of cases they lose their money. But it makes it difficult for a stranger to buy a prospect except at an exorbitant price.

After that I took over the management of a gold-quartz mine belonging to a local company, and was there about six months. They had two wooden 10-stamp mills, into which I put plates. But the ore only ran about $5, with a narrow vein, not enough to stand much development expense, so that when stoping overtook development, it was up to them to put their hands in their pockets to keep the mine going. They refused, and it was closed down.

This country seems to be attracting attention. Ben S. Revett has a party of 25 white men prospecting placer ground in the Choco for the Consolidated Gold Fields of South Africa; and the Oroville Dredging Co. of London is putting up an electric generating plant on the Nechi river, a tributary of the Cauca and also building a dredge at Zaragoza. If they make a success of it, it will give the country a big boost. Wernher, Beit & Co. have six engineers in Antioquia looking for properties and have taken over the Marmato mines, and are said to intend putting up a 100-stamp mill, to work the whole hill by the open-cut method.

Goldfield Consolidated Report

During the month of October, according to the report of J. F. Thorn, general superintendent of the Goldfield Consolidated Mines Co., the total production was 30,626 tons, containing $860,154, or an average of $28.09 per ton, the whole being milled with an average extraction of $26.77 per ton, or 95.31%. The total net profit was $616,142, or $20.12 per ton. During the month 3152 ft. of development work was performed. The total cost of mining, development, milling, office and general expense was $6.80 per ton, distributed as follows:

Mining:		
Development	$0.83	
Stoping	2.04	
		$2.87
Transportation		0.08
Milling		1.96
Marketing		0.74
General expenses		0.38
Bullion tax		0.31
Construction		0.46
Total cost of operation		$6.80
Miscellaneous earnings		0.15
Net cost per ton		$6.65

In the Clermont the 466 intermediate between the 600 and 750-ft. levels, and just south of the 428 and 401 stopes, has been extended 30 ft. and produced 153 tons of ore averaging 1.53 oz. This orebody has also been found by a raise from the 427 drift (750-ft. level) 150 ft. south of the 483 cross-cut, at a height of 20 ft. above the level. The 413 sill was considerably extended during the month, and produced 879 tons of ore averaging 2.87 oz. The continuation downward of the 413 orebody was again proved, first by 420-I raise, driven in the hanging wall of 420-H raise, at a point 60 ft. under the 413 sill, and again by 420-K raise, driven from the 750-ft. level opposite 420-H and into the hanging wall, which intersected the ore at a height of

35 ft. The average content of the ore exposed is 2 oz. The 510 sill from 521 intermediate was extended and produced 156 tons of ore averaging 1.02 oz. The Grizzly Bear shaft was sunk to a depth of 95 ft. below the 1200 ft. level.

In the Mohawk the No. 20 and 21 cross-cuts from No. 3 drift have been cut for a sill, and produced 653 tons of 1.55 oz. ore. The sill in No. 13 drift was extended and produced 375 tons of ore averaging 2.11 oz. The continuation downward of this ore was proved by a raise from the 290 intermediate, which intersected the ore 40 ft. vertically under the 13 sill. On the 450 ft. level the 345 sill was extended and produced 145 tons of 1.89 oz. ore. The 101 sill of the Red Top was extended and produced 563 tons of 5.62-oz. ore. The 477 intermediate was advanced in ore, producing 151 tons of 1.67 oz. content. A cross-cut in the hanging wall of 305 drift, 180 ft. north of the main cross-cut from the shaft, produced 19 tons of 5.05-oz. ore. The Hazel shaft of the Laguna was cleaned out to the bottom, and the drifts on the 718-ft. level cleaned out preparatory to prospecting the quartz mass in this area. The 136 sill in the Combination was extended and produced 422 tons of 3.92-oz. ore. The mill tonnage for the past month, 30,626 tons, was the largest for any month since the mill has been in operation. The construction of the concentrate-residue treatment-plant is progressing at a satisfactory rate.

Petroleum in New Zealand

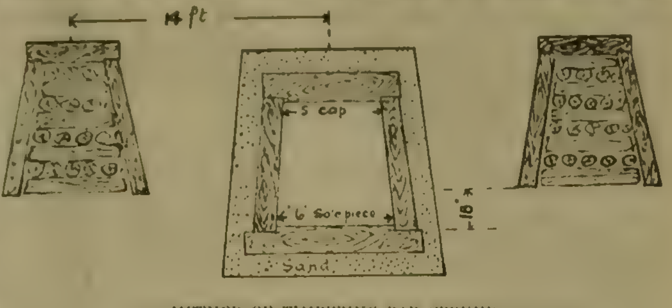
London Correspondence

The oil resources of New Zealand are to be introduced to the public once more during the next month or so. These have been known long enough and have been boomed before in London; but for several reasons their output has been restricted and most of the ventures have been failures. With the increased knowledge of handling petroleum deposits that is now current, the new scheme should prove more successful. The deposit is on the coast at Taranaki, near the famous three Sugar Loaves sighted by Captain Cook in 1770. In 1838 attention was drawn to Taranaki because it was considered a suitable district for the formation of a colony, and this agitation caused the British Government to annex New Zealand before France obtained possession. The presence of oil in the district was known to the earliest settlers, for it was found floating on the sea round the Sugar Loaves, and the Maoris had a tradition that the oil was the result of the burning of bituminous matter in a submerged island. It was not until 1865 that a technical examination was made. In that year samples were sent to London, and prospecting licenses were granted by the Government. Boring started in 1866, and gas and oil were struck at a depth of 20 ft. and 60 ft. respectively. Just at that time the New Zealand Geological Survey was created, and James Hector was appointed as chief. His first commission was to report on this new oilfield. The first ventures were not successful commercially, and the development of the district lay in abeyance until 1888, when interest was revived by H. A. Gordon, the inspecting engineer of the Mines Department. In 1889 companies were floated in England to continue the work. There was another boom in 1906. The Taranaki coast is also noted for its deposits of iron sand along the seashore, but the commercial value of these has never been ascertained.

New Method of Driving in Bad Ground

A few months ago, at the New Langi Logan mines, much difficulty was experienced with 'heavy' ground in the new main drive; but it has been completely overcome. W. H. Toole, the manager, devised a method, purely his own, of remedying this trouble, which for a time threatened to defeat every effort to keep the main drive open. There was an entire absence of any layers or strata; the whole of the country rock being crushed into small blocks, and forming what appeared to be a huge dike or cross-course. Altogether about 350 ft. of this ground has been passed through. The accompanying sketch will help to explain how the difficulty was overcome.

The manager's first object was to exclude the air. This was accomplished by cutting the drive larger than usual, a layer of finely crushed rock was then laid in the bottom of the drive, in which 12-in. sole pieces were bedded; when the sets were put in the fine sand was continued up the sides as shown, and formed a packing 12 in. thick between the laths and the sides of the drive. The whole was then double-lined with 12-in. timbers—all on sole pieces.



METHOD OF TIMBERING BAD GROUND.

The next step, and probably the most important of all, was to drive two small relieving drives parallel to the main drive, and about 7 or 8 ft. away. These drives were afterward 'horsed up' with firewood. The drive, at this point and throughout, is now perfectly sound, and has been standing for over three months without showing the slightest signs of crushing.—*Australian Mining Standard.*

Mass Copper

An interesting point in regard to the large masses of native copper, described on another page by T. A. Rickard, is the difficulty which they offer to extraction by any ordinary means. The very great toughness of metallic copper is seldom fully appreciated by those who have not learned by experience, and the loungers on the docks at Hancock find a perpetual source of amusement in the efforts of innocent tourists to break off a small fragment of native copper from the masses on the docks, as a souvenir. When large masses are found in the mine, high explosives are of little use in reducing the mass to fragments of a movable size, and the work required in cutting up such masses with a chisel is so expensive as to consume the larger part of the profit from their extraction. An oxy-acetylene torch might be of service in this connection, but there is no record of its having been so used.

A GROUP OF MINERS POSING BESIDE A MASS OF COPPER (WEIGHING FIVE TONS), WHICH THEY ARE CUTTING WITH CHISEL AND HAMMER.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

PROUSTITE is often called light ruby-silver, just as pyrargyrite is known as dark ruby-silver. The former is a sulph-arsenide, and the latter a sulph-antimonide of silver.

CADMIUM is imported into the United States as metallic stick cadmium and as the pigment, cadmium sulphide (CdS), known as cadmium yellow. The former is free of duty; the latter is dutiable at 30% ad valorem.

ADDITION of small quantities of certain substances, such as CS_2, solutions of iodine, or guttapercha in chloroform, or some heavy hydrocarbons, to electroplating baths increases the density, brightness, and non-crystalline character of the deposited metal.

LOGS are occasionally cut several inches longer than necessary, and thus several inches must be thrown away. Another waste results from splitting stock instead of sawing it. Much wood is lost because of small defects which a saw would remove, but which cannot be split out without sacrificing more or less good timber.

RHODONITE, though a silicate of manganese, is of no economic importance and is not included with the ores of manganese. It is a brownish to bright red mineral and may be mistaken for red feldspar or rhodochrosite. But the latter dissolves with effervescence in warm acids, while feldspar is less fusible and does not give the manganese reactions.

SULPHUR is used in immense quantities for the manufacture of sulphuric acid, gunpowder, matches, rubber goods, bleaching powder, and medicines. Large quantities of it are recovered in various chemical and metallurgical operations as by-products, but the chief source of supply for the United States is the natural deposits of Louisiana, where it is obtained from deep-seated strata by the Frasch process. Large quantities are also imported from Japan and Sicily.

CITY water often contains large quantities of lime and magnesia in solution, and these coming in contact with the heated walls of the air-compressor precipitate in the form of scale. This scale cuts down the radiating capacity, the air-compressor overheats, and the efficiency is very greatly reduced. Not only this, but, due to the pressure, the water in the jackets has been known to leak through the packing and get into the cylinders, causing wet air with its attending troubles.

AN alloy suitable for small metal patterns is composed of tin, one part, and lead, one part by weight. The result is a somewhat soft alloy which requires care in the handling of the patterns. Some harder mixtures are as follows:

Lead.	Antimony.	Tin
55	30	15
55	22.7	22.3
61.3	18.5	20.7

THE point was made in a recent discussion on safety attachments for machinery that the designer was not called on to make his machine 'fool-proof,' but only to make it safe. The argument was raised that to overdo the protection of moving machinery was not only to make the cost of the machine prohibitory when many were to be used, but also that a safeguarding which was too complete was demoralizing to the operator, in that it made him careless and what may be called 'sloppy' in his mental attitude. A certain alertness incident to a knowledge that the machine has capacities for harm is derived from the use of a machine made safe, but not completely 'fool-proof.' That alertness represents a certain sort of attention to his work which makes a man more valuable, and for a longer time.

SUCKER-RODS used in pumping oil wells are preferably made of hickory, though ash will serve. These rods must be clear and straight pieces from 18 to 35 ft. in length, long strings of them being coupled end to end to reach the bottom of deep wells. Hickory will sustain nearly as much load on a longitudinal pull as a rod of iron of the same size, and it weighs less than half as much. Sucker-rod buyers demand the best parts of the choicest hickory. Skewer manufacturers are making some use of hard maple, beech, birch, basswood, and persimmon. Hickory, however, imparts the least taste, and will not break or splinter when thrust into the meat or candy. Ash and hard maple are used to some extent for picker sticks. The strength and toughness of hickory, however, places it first for this purpose.

FALLING bodies are responsible for many accidents. In the *Bulletin* of the Department of Labor of the State of New York the number of accidents due to the fall of objects in course of manufacture or undergoing repair by the injured person is given as 773. These are mainly injuries to the fingers. Objects being moved or carried by hand caused 447 accidents, of which 168 were to the fingers or the feet. Objects being loaded or unloaded on vehicles hurt 343 persons as respects either fingers or feet. Falling objects which were not dropped by anybody, but fell on the victim, caused 460 accidents. Injuries caused by vehicles and animals resulted in 225 cases. It will be interesting to note that locomotives and trains caused only 81 accidents in the list given. This must be by reason of the inclusion only of such accidents as occur within the walls of a factory.

A LOCATOR may change his boundaries or the name of his claim at any time, provided he does not interfere with existing rights. He may even swing his claim at right angles. However, he should hold substantially to the same ground as before, and if possible use the same discovery or location point. While it is clear that the rights of others shall not be interfered with in changing boundaries, it is not certain what would be the result where a claim-owner, having done the amount of work required for patent purposes upon his claim, should swing part of his claim over upon the valuable locations of others and immediately ask for patent, while the senior locators of the ground now in conflict would fail to adverse through presuming that the claim up for patent was still occupying its original position, but would afterward discover their loss. The only redress that appears would be to attempt to take the matter into court asking that the patent owner be declared to hold the conflict area in trust to be conveyed to the defrauded locators.

HICKORY is the world's foremost wood for certain purposes, because of its combination of strength, toughness, and elasticity. It offers excellent resistance to strains, twists, and shocks. The superior place held in many countries by the American axe is due as much to the hickory handle as to the steel in the bit. The same may be said of American hammers. The enviable reputation of harvest machinery made in the United States has placed it in every important grain-producing region of the world, and to the use of hickory is due much of its success. Other woods are satisfactory for heavy vehicles where strength is the chief requisite, but for light, graceful, handsome, springy buggies, carriages, and traps hickory is unequaled. It goes into wheels, poles, shafts, spring bars, and other straight and bent parts. The lightness and resiliency of the American racing sulkies has won universal admiration, and their superiority is due to hickory. The severe thrust, strain, twist, and compression which automobile wheels must sustain demands spokes of absolutely the best material obtainable, and for this the manufacturer is dependent on hickory.

Special Correspondence

MEXICO

Mexicans May Make Oil Lands Subject to Denouncement.—Labor Troubles and Rumors of Rebellion Disturb Business. New Mining Developments.

A bill making oil lands open to denouncement, placing them on the same basis as mineral lands, has been introduced in the Chamber of Deputies by a congressman, José Maria Lozano, and is attracting much attention. The measure seeks to do away with oil concessions, and to provide against the possible control of the oil supplies of Mexico by the purchase of land. In introducing his bill, Lozano said: "A sale of the Pearson oil interests to the Standard Oil is now pending, and if we do not pass this bill a time will come when the old Viceroy's palace and the Castle of Chapultepec will be ruled from Wall Street, as the Standard Oil money will buy the votes and the magistrates, the courts and the deputies, the senators and the presidents. I want to keep Mexico out of reach of the golden arms of the ferocious octopus." According to a recent report, Lord Cowdray has been negotiating with the Standard Oil for the transfer of the Pearson holdings and oil business. The Lozano bill will come up for discussion soon, and developments will be awaited with great interest.

GREENE-CANANEA CONCENTRATOR.

Mexico has been having more labor troubles, several thousand workmen at Torreon going on strike, with a demand for increased wages and an eight-hour day. The strikers included employees of the Torreon custom smelter, which is controlled by the Madero interests. It is reported that the strike fever has spread to workmen of the Velardeña smelter of the American Smelters Securities Co., and that the employees of the Mapimi smelter of the Peñoles Mining Co. are ready to walk out. Many of the Torreon strikers have returned to work, and the labor troubles may be of short duration. The Chihuahua smelter of the American Smelting & Refining Co., which closed several months ago as a result of labor troubles following the triumph of the Madero revolution, only recently resumed operations. Reports that General Bernardo Reyes, who recently was arrested in the United States, was planning to launch a revolution against the Madero government, are causing uneasiness in business circles, notwithstanding the declaration of President Madero that the new government is in a position to quell any uprising. He has announced that bandits and those who rise in arms against the Federal government will be crushed with an iron hand. An appropriation of ₱14,000,000 for army increases has been made, the greater part of the money to be used in organizing additional regiments of rurales.

In the month of October the Greene-Cananea company had a record production of copper, the output reaching 6,000,000 lb. Of that amount nearly one-third resulted from the Miami concentrate, the Cananea production being 4,058,000 lb. The gold production in October—763 oz.—established a record for Greene-Cananea, and the silver output—127,568 oz.—was the next to the largest since the present management assumed control. The copper cost of 9c. per pound, which was reached some months ago at Cananea, is being maintained. In October the Lucky Tiger G. M. Co. shipped 78 bars of bullion valued at ₱95,000. The company's new cyanide plant is working successfully, and operating costs have been reduced by bringing in electric power from Douglas, Arizona. It is now expected that the new 100-ton smelter of the Sonora Copper Co., near Noria, a station on the Sonora division of the Southern Pacific, will be in operation about the first of the year. An aerial tramway that will carry the ore to the smelter is being completed. The mines have been under development for several years.

JOPLIN, MISSOURI

Zinc Ore Prices Touch Highest Figure of the Year.—Smelters Constructing New Plants.—Zinc and Lead Notes.

The latter part of November saw the price for zinc ore go above $50 per ton, on an assay basis of 60% metallic content—the highest figure of the year. Mine operators had grown discouraged with the long-continued low prices, and talk of a general shut-down of the heaviest producers was current. Even with the advance in offerings, many operators did not feel that the ratio between metal and ore was fair to the miner. With East St. Louis spelter quotations at $6.60, they felt that bids should range from $50 to $52 per ton, basis. Instead, the open market offerings failed to pass the $48 mark, and only the ores sold on contract to the American Zinc, Lead & Smelting Co. commanded a basis in excess of $50. Conditions at present are generally satisfactory, the production and shipments being about 5500 tons per week, the heaviest of 1911.

Inadequate smelting capacity has caused stronger metal prices, due to the fact that the present plants are unable to meet the heavy demand for metal. Several companies are constructing new furnaces, a number of idle smelters are to resume operation, and several large new smelters are being constructed at various points, chiefly in Illinois and Oklahoma. A great quantity of Colorado calamine has flooded the smelters of the Oklahoma and Kansas natural-gas belts, and because of the peculiar qualities of this Western ore the metal output has not been so heavy as might be expected. The National Zinc Co. began the erection of two new blocks at the Bartlesville smelters early in the fall, and they were put in operation the last week in November. The Prime Western company's plant at Collinsville, Okla., also was increased by the addition of five blocks. During the ensuing year a heavier smelting capacity will be available through the construction of a number of new furnaces, now under course of erection. The American Metal Co. is constructing a remodeled plant at Collinsville, much of the material coming from the old Lanyon plants at Iola, Kansas. In many of the new plants, steel and concrete are used extensively, and thoroughly modern smelting methods are being employed. At Nevada, Missouri, the old Cockerill Zinc Co.'s plants have been taken over by W. H. Robertson and B. K. Blair, of Webb City, and extensive repairs are being made. The new company expects to be turning out metal by January 1.

Amasa Corbin, owning extensive mining lands in Galena, Kansas, and representing the East Empire Syndicate, owning additional tracts, has arranged for extensive development and pumping in what was the banner camp of the Missouri-Kansas district in the early days of the Galena region. Fabulously rich turn-ins were made from comparatively shallow mines on these properties; the ground was extensively cut out to a certain level, but below this no development could be undertaken because of the water which baffled the ingenuity of the early-day pump operators. A. M. Gaines and associates have now leased large tracts of the lands mentioned, enormous pumps are to be installed, prospect drills are to be put to work, and hundreds of acres are to be mined if the lower runs of ore prove even partly as rich as were the deposits near the surface. With the lands well drained and several large companies at work, the output from this part of the camp should materially increase Galena's weekly production, which is now averaging less than 1,000,000 lb. of blende.

After months of tireless pumping, during which millions of gallons were lifted, the Carson-Dodge company, in the North Miami, Oklahoma, field, has penetrated the deep zinc and lead formations intersected in drilling early in the spring, and heavy turn-ins are beginning to be made. The mill dirt occurs at a depth of 280 ft., extending to 320 ft., and carries about 25% zinc and lead, of which 60 is zinc and 40% lead. Chapman & Lennan, drilling on an adjoining lease, discovered a 40-ft. ore deposit and are now sinking a shaft. Galena clippings in several drill-holes were so rich that the water taken from the drill-holes resembled ink. Heretofore development at Miami has been conducted at the 90-ft. level, extending down to 160 ft. Between the upper formation and the extremely deep ore, intermediate runs of ore have been penetrated in drill-holes sunk at the extreme west edge of the district. The discovery of this deep formation, which shows every indication of covering a great area, is considered one of the most important features of mine development of recent years.

Open-cut mining methods are to be adopted at the Wyssbrod M. Co.'s property in the Zincite district, west of Joplin. Where an old cave-in occurred years ago, the débris is to be removed, a large concentrating plant is to be erected, and the dirt from the surface down to a depth of 150 ft. will be milled. The mineralized dirt, in places, reaches to within a few yards of the surface. In other open-cut operations throughout the district it has been found cheaper to mill the entire deposit, from the surface down, rather than endeavor to first scrape away the thin stratum of surface soil, which carries no ore.

Zinc and lead, occurring in a thin but very rich stratum, were found recently in several drill-holes sunk near Butterfield, in Barry county, Missouri, a region remote from the developed zinc and lead area. The first find was made by drillers who were seeking water. Other drillers, in quest of ore, promptly invaded the field, and several encouraging finds have been reported. The ore is found, in most instances, at a depth of 120 to 125 feet.

LONDON

Popular Subscription Necessary to Maintain Camborne School of Mines. — London Financiers Actively Seeking Larger Tin Supply. — Progress in South African Tinfields.

The facilities for technical education in connection with metallurgy and mining, apart from the branches relating to iron and coal, are still not so great as they should be in a country like England, that controls mines of all sorts in all parts of the world. It is true that the Royal School of Mines has been put on a satisfactory and permanent basis as part of the Imperial College of Technology, the new Bessemer laboratory has been added to its equipment, and a handsome College Union building has been opened to provide the necessary social amenities for old and present students. But much more has yet to be done in extending teaching facilities. This is not an immediate need, and in any case the improvements can be made gradually and as opportunity offers. A much more pressing matter is the future of the Camborne School of Mines. This was recently amalgamated with the smaller schools at Penzance and Redruth, and its control came under the Government Education Department in accordance with the new Education Act. It still lacks the dignity required for State aid, because it has no recognized standard entrance examination or course for a degree. In fact, it is only "a place where mining is taught," and not a college or university. At the present time the school is being run at a loss, and the deficit will become alarming unless something is done, and that quickly. Unfortunately, the school has hardly any endowment, though it owes much to private generosity for its buildings and equipment. But the benefactor who gave the land took care not to part with any of the best sites on his books, and consequently the student is struck with dismay when he first makes acquaintance with the approach to the school. The governors have placed their position before the Royal Commission on Metalliferous Mining now sitting, though such a policy seems to be one that will lead to nothing, and in fact to be a step in the wrong direction. They ask the State and the County Council to make good the annual deficiency, and to provide just a little more to keep things going. It is impossible to raise any more money in Cornwall from private sources, for Cornish mining is not sufficiently profitable. The only people making money liberally in Cornwall out of mining royalties are Lords Falmouth and Clifden, who draw large incomes from their china-clay estates. It seems hopeless to expect them to interest themselves in the Camborne School. Nor could C. S. Goldmann be expected to provide money at present, though he might be inclined to consider the proposition some other time. He is a Member of Parliament for the towns of Falmouth and Penryn, and the law is so strict in England that if he paid out any money for a college he would be unseated for bribery and corruption. He is rich enough, being a Rand magnate connected with the Neumann group, and he lives at beautiful Trefusis on the opposite shore of Falmouth harbor. What the governors ought to do, and what I am doing now, is to advertise the present position of Camborne School to Cornishmen all over the world, and to ask them to subscribe to a fund for the provision of a suitable endowment, and for additional buildings in a more dignified position. I hope that both the governors and Cornishmen generally will take this hint.

Tin is a metal much sought by financiers in London, and anybody with a reasonable proposition will be received with open arms. Much money is being spent in South Africa in the investigation of geological formations favoring the presence of cassiterite, and we have recently heard much of the Abercorn and Victoria districts, in Rhodesia, both of which are promising. The yearly progress reports of the two leading producers in the Transvaal have once more drawn attention to the possibilities of the Waterberg and Rooiberg districts. The Rooiberg company, though it only started development in the summer of 1908, earned a profit of over £50,000 during the year ended June 30 last. During that period 17,781 tons of ore was raised and treated, averaging 7% tin, and 1077 tons of concentrate was produced averaging 67%. The recovery was not high, being only 58%. The reason for this is that the imperfect experimental machinery was still being used. Edward J. Way, the consulting engineer, and Amos Treloar, the mill manager, have designed a modern plant which will cost £40,000, and this will be at work shortly. By its means the extraction will be greatly improved; not only so, but the accumulated slime and middling will be treated. The reserve of ore on June 30 was 21,650 tons averaging $4\frac{1}{2}\%$, but the engineers point out that this average is unreliable, for thin seams of pure cassiterite are being continually found during stoping that could not be detected when estimating reserves. They have found by experience that the mill-screen samples are almost always higher than those taken in the mine. Unfortunately, as with other mining operations in South Africa, this mine has suffered from scarcity of labor, and the scheme for increased development is in abeyance.

The other tin-mining company in the Transvaal, the Zaaiplaats, is further advanced, so is able to make greater profits. The present report covers the year ended July 31, and shows that 24,105 tons of ore was crushed, yielding 1763 tons of concentrate, averaging 70% tin. This sold for £190,553, out of which £111,000 has been distributed as dividends, being at the rate of 185% on the capital, £60,000. Until the present time the battery has consisted of 5 heavy stamps and 10 light ones; the latter are now being replaced by 1550-lb. stamps similar to the other heavy ones. This has been made necessary by the increasing hardness of the ore. It is further announced that another 20 are to be added, as the extent of the orebodies is found to be far greater than was at first supposed. Additional dressing plant equipment also will be required, as the cassiterite tends to become of finer grain and more disseminated in depth; also, a roasting-furnace to deal with the pyritic matter which is making its appearance. A voluminous report on the property by Hans Merensky has recently been published; it was due to the information therein contained as to the great extent of the deposit that the directors decided to increase the scale of operations.

TORONTO, CANADA

New Equipment for Porcupine Mines. Dome Mill to be Ready March 1. Development Notes of the District.

There will be great activity in the forwarding and installation of machinery in the Porcupine district, as soon as the winter has fairly set in, with the roads in good condition for transportation. At the Dome, where the expenditures on construction and development so far are estimated to run close to a million dollars, rapid progress lately has been made, and it is announced that the mill will be in operation by March 1. It has been decided that only low-grade ore will be treated for about a month, in order to wear down the stamps into good condition and to give opportunity to make the necessary adjustment in the working of the plates. Ambrose T. Monell, managing director, says that as regards ore, the only certainty is as to the surface and down to the 50-ft. level, at which depth there are two drifts, one of which runs uniformly for 136 ft., carrying ore assaying $28 per ton, and the other running parallel shows $30 and for the last 20 or 30 ft. $40 per ton. Below that level diamond-drilling shows good ore, and under the 'Golden Stairway' the same process gives high gold content at depth, though it is not possible to strike an average. There is no question, however, of the enormous quantities of milling ore occurring on the property. A second shaft is being put down on what is known as the 'second dome' for the purpose of getting to the north side of the lenses of quartz that project in parallel rows, overlapping each other.

The Vipond is expected to be early in the field in actual milling operations. The mill will be erected on the Hardinge system, with a tube-mill and pebble mills in place of stamps. The ore will be crushed to 200 mesh before it will be amalgamated. It is so free-milling in character that for a time the company will dispense with the cyaniding process, until at least the tailing has accumulated. As in the case of the Dome, the earlier treatments will be of lower grade ore. The Doric is getting in new equipment, including a 9-ton locomotive boiler to give additional power, and a hoist for work in the deeper levels. W. R. Bauder has assumed the management of the McIntyre mine, where the sinking and underground development work, amounting to 750 ft., has demonstrated a considerable orebody. A 10-stamp mill will shortly be built.

At the Hollinger the machinery of the mill is being put in place. Connections are being made at the 200-ft. level of the shaft, which will be put down to 400 ft. with a station at 300 ft. It is hoped to have the mill in operation by March 1. It will have a capacity of 250 to 300 tons. The orebody at the Miller-Middleton shows a width of 10 ft. A shaft is down 50 ft. on the bluff and a cross-cut is being run in connection with it. The Apex, which has two shafts sunk to about 40 ft., has let a contract to put them down to the 110-ft. level. Two 80-hp. boilers and an 8-drill compressor have been installed. The main shaft of the Eldorado is down 28 ft. and has found many quartz stringers. The option held by B. E. Cartwright on the McAuley claim, Bristol township, has been dropped, as the gold content shown in 80 ft. of sinking and 1200 ft. of driving was only 80c. per ton. A report of the operations of the La Rose Consolidated presents a favorable showing. During the first nine months of the year the output amounted to 2,751,946 oz. of silver, with a gross value of $1,444,271. The shipments during this period amounted to 3,179,958 oz. The income was $1,453,958 and the expenses $536,868, leaving an operating profit of $916,765.

At the Nipissing the hydraulic pump installed for the removal of the overburden next spring on a large scale has been tested and proved satisfactory, throwing a stream of 4800 gal. per minute with a head of 415 ft. Recent development work on the Trethewey has opened up large bodies of milling ore. A 3½ in. vein on the 100 ft. level has for 200 ft. a wall rock for 6 ft. on each side heavily charged with silver. A smaller vein on the Nipissing boundary, which has been opened for 60 ft., carries 3000 oz. per ton with 5 ft. of milling ore on each side. The Temiskaming has passed its dividend for the current quarter in order to raise funds for the purchase of a controlling interest in the North Dome of Porcupine, taking 138,000 shares for which it will pay $229,000 or about $1.66 per share.

The Crown Reserve recently has opened some new ore shoots, the principal being on the 170-ft. level, where the Ross vein shows 4 in. of high grade ore. A winze put down to the 200-ft. level and cross-cutting at that depth show the ore to be persistent. The shoot, which is 70 ft. long, occurs in the Keewatin formation.

NOME, ALASKA

Dredging Output Smaller Than Last Year. -Pioneer Clean-Up.- Weather Mild.—Development in the District.

Although several dredges are still running and their output will increase the returns from this season's operations quite materially, it is clearly evident that the 1911 output from Seward Peninsula will fall below its output for 1910. The gold shipped so far this season, according to Customhouse returns is $2,815,425.64, while for 1910 it was $3,482,319.32 on the same date. The falling off is due entirely to a decrease in the output last winter as compared with the year before. The output this summer has been greater by several hundred dollars than what it was last summer. This increase is due to the many dredges that have been operating so successfully this season.

DRILLING TO RECLAIM A FLOODED DRIFT MINE.

The Pioneer M. Co., which in the spring of 1910 cleaned up $700,000 from its winter dumps, did not take out a dollar last winter, though its output this summer has greatly exceeded its output of last summer. The season has been an exceptionally long and favorable one.

Ditch owners, believing the real freeze-up had arrived, turned the water out and laid up equipment for winter. However, the cold snap passed quickly, and up to today, November 1, sluicing of all kinds could have been carried on just as well as in August. Nor does it appear at this time that freezing weather is likely to come for some time. Small operators pumping water around the tundra and some small sluicing operations around the nearby creeks are still going on, but all large operations have been closed since the first of October.

The Wild Goose company has done a large amount of drilling and other prospecting in the Nome district this summer, but its attention has been centred on Ophir creek in the Council district. The Fairhaven Ditch Co. seems to be at last coming into its own. It has worked two hydraulic elevators all summer, and their output is not much short of $100,000, according to some testimony that was given in a lawsuit here some time ago. Much work was done in the Kougarok district this summer, but I have been unable to get a Kougarok operator to make an estimate of the output for this season, though I have talked with most of them.

The Taylor creek ditch, under the management of Joe Mathews, has worked two elevators and quite a crew of men. The Davidson ditch, under the management of the Pioneer company, has also done a good deal of work. Many small operations have worked as usual, but it is probable the total is less than $150,000.

The Candle creek district has a little new life infused into it by the starting of the Candle Hydraulic Ditch Co.'s operations under Leo Loewinherz and others who bought the property in at a judgment sale. The Squirrel river excitement of last winter in which Nomeites were so much interested proved to be short lived. Some very rich spots were found on the creek, but it was too limited in extent to amount to much. There are about fifty people in the camp at present and some further prospecting is still being done.

Nome is trying to follow the lead of Fairbanks and develop a quartz camp. A number of public spirited citizens, led by Conrad Freeding, W. A. Gidmon, Joe Jordon, and Russ Downing, have had a stamp-mill built on the bank of Dry creek back of the town, and the citizens now rise in the early morning at the signal of the stamp-mill whistle and the rumbling of the stamps as they crush the quartz that is being hauled in from various prospects for testing purposes. The mill consists of two, 2-stamp, triple-discharge batteries of Joshua Hendy standard type, fed by Challenge automatic feeders. The ore is first fed through a 7 by 9 Blake crusher and falls into a bin from which it passes through chutes to ten automatic feeders and to the stamps. The crushed material passes over a plate surface about 4 ft. wide by 12 ft. long and is delivered by a launder to a No. 2 Deister table where the concentrate is saved. The ore treated the day the mill opened returned $34 per ton in free gold. Just now there is quite a little activity in developing quartz prospects in the nearby hills and the mill is kept busy testing small lots of ore, from a half ton to several tons. The power used in the mill is steam and so far they have burned coal, but Mr. Freeding says they will shortly change to crude oil.

NEW YORK

Metal and Stock Markets Active. — Amalgamated is Higher than Steel Common.—Situation Analyzed. — Arizona Developments. — Greene-Cananea Dividend Expected.

Coppers have held the centre of the stage in the New York markets during the past week. The metal market and the share market are enjoying more activity than has fallen to the lot of either for several months. A 13c. copper market is now spoken of as an assured fact. There have been advances all along the line in the leading copper shares, and traders on the New York Stock Exchange have made much of the fact that 'Copper', as Amalgamated is known in Board parlance, is selling for more than Steel common. Just how much of the present movement is due to sentiment and how much to an early discounting of real conditions is hard to tell. To say that business conditions had so far improved as to create a marked increase in the demand for copper would seem to be a little audacious. Recent heavy sales of copper are said to have been mostly of 'spot copper', that is, for November and December delivery, which would indicate that domestic consumers are still pursuing a hand-to-mouth policy and are not attempting to stock up in anticipation of higher metal prices. There have been several factors that have been instrumental in making for low prices in copper: the weight of the existing surplus, the added production from several new important producers, the general prevailing stagnation in business, especially in new constructive enterprises. To say that any of these elements have been so far removed as to justify the present advance would be a rather radical statement. Amalgamated's leadership of the copper list and its place as a favorite speculative issue on the New York Stock Exchange has, as is well known, nothing to do with its intrinsic value: Amalgamated's quotation around 65, with a dividend distribution of $2 per year, is one of the familiar market absurdities of Wall Street. It may be added that, if conditions are found to really justify higher levels for copper metal, the stimulus to production will be such that there will be grave danger of a sudden increase in the surplus and that it will assume within a few months threatening proportions.

The development of the Inspiration, which adjoins the Miami, near Globe, Arizona, is being pushed as rapidly as possible, and this property will be one of the next to join the ranks of the producing mines. The plant to be erected is to handle 5000 tons of ore per day; water is to be brought from Wheatfields, Arizona, where large reservoirs are to be constructed, the dams being already in course of construction and surveys made for the pipe-lines. Ray Consolidated, which is probably the most important of the group of developing coppers, from which a large output is looked for in 1912, has been producing at a rate somewhat less than was expected. Sherwood Aldrich, president of the company, who has just returned to the East from an inspection trip, explains that some low-grade ore, near the edge of the main orebody, had to be handled at this time to get it out of the way and to avoid sinking another shaft later, if it were not milled now. Next month, it is said, the Ray mill will handle 5000 tons per day, as compared with 3700 tons treated now. The average recovery is about 28 lb. of copper per ton. Ray Consolidated has been one of the active issues in the recent advance, moving up from around $12.50 to $16. Charles Hayden, of Hayden, Stone & Co., of New York and Boston, was one of the party, which has just returned from a trip, which included visits to all of the Guggenheim string of porphyries, Utah Copper, Nevada Consolidated, Ray, and Chino. Mr. Hayden is evidently much pleased with the outlook at all of the properties mentioned. The two older properties of this group, Utah and Nevada Consolidated, are prepared to produce at full capacity whenever the metal market will justify such action. The October output for Utah Copper was not so large as that for August or September, but the Nevada Consolidated made more copper than it has in any month since March. Utah produced 8,660,729 lb.; Nevada Consolidated, 5,547,131 lb. of copper.

Attention is called to the showing made by the Lake properties in 1910. Total output for Lake Michigan copper mines was 222,683,000 lb., or about one-fifth of the output of the American mines. Ore tonnage is computed to have been 10,869,561 tons, from which an average recovery was made of 20½ lb. per ton. The fact that from rock of this low content, with a market at practically 13c. for the entire year, the Lake mines were able to pay $6,240,526 in dividends, shows that not all of the skill in winning profits from low-grade ores belongs to the porphyry operators.

The better feeling in coppers has not been all confined to this side of the water: there has been an active market and higher prices in Rio Tintos, which are traded in on the Paris Bourse, and, like Amalgamated Copper shares, are favorites with the speculative element.

In precious-metal mining there is almost nothing afoot in New York. There is evidently to be a strong effort made to galvanize some life into the Porcupine issues. There has been some trading in the shares of the 'big' Dome around $40 per share, but so far the public has not followed the market with any interest.

The situation in Mexico has been so uncertain that no new Mexican mining enterprises have been fathered in New York for a long time, and recent developments seem to point to further unsettlement rather than a restoration of tranquillity. Some American interests are again becoming uneasy, and that there is reason for uneasiness is evidenced by the action of the War Department in massing soldiers upon the border and the issuance of emergency orders to troop officers. Pedro Alvarado's Palmilla mine, one of the most widely advertised properties of Mexico, about which clever newspapermen delighted to invent fantastic tales of fabulous wealth, is now ensnarled in a mass of litigation between two of the Boston promoters who took the property over from Alvarado.

General Mining News

ALASKA

Juneau

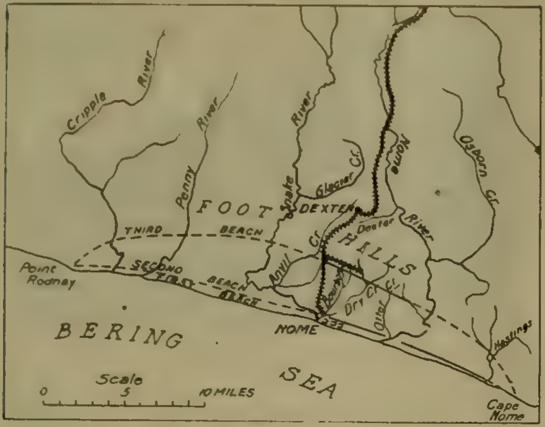
The Alaska Mexican G. M. Co. paid a dividend of 20c. per share on November 28. The Alaska United G. M. Co. paid a dividend of 30c. per share, and the Alaska Treadwell G. M. Co. a dividend of 50c. per share on the same date.

Prince William Sound

Rich ore has been found by Ralph Williams in an adit on the Shoup bay property owned by Tiffany & Boyle. The ore is said to be as valuable as that found in the cropping.

Seward Peninsula

Reports from Nome state that rich gravel has been found on the third beach line. The ore was found by H. R. Bounds, who has been prospecting on Cunningham creek. The gravel is said to extend along the old beach line for about four miles.



BEACHES AT NOME.

The Tanana

Reports from Iditarod state that Harry Johnson, Al Burke, and Jonas Bruce have found an unusually rich 'pay-streak' on the right limit bench of Flat creek.

The ground on Allen creek for five miles has been staked recently, owing to the discovery of a small nugget and rich sand by Morris R. Moon, says a report from Fairbanks. Allen creek is tributary to the Goldstream. The discovery was made on the Asia association claim.

Near Ester, Tyndall & Finn have purchased a two-thirds interest in a claim at the head of St. Patrick creek, operated by Pat McLaughlin.

ARIZONA

Gila County

(Special Correspondence.)—The experimental mill at the Inspiration is expected to start this week, and J. M. Callow, consulting metallurgist, is now at the mine and will supervise the tests. Topographical surveys are in progress at Wheatfields, eighteen miles from the mine, which is the site of the proposed dam and pumping station. The foundations of this dam are now being tested. There is practically no underground work going on at present.

Churn-drilling continues at the Live Oak, there being four drills in operation. The cutting of the station in No. 2 shaft at the 800-ft. level has been completed and driving on the orebody will be started. Driving is also being done from No. 1 shaft, on the fourth level. This drift is in the orebody.

Churn-drill hole No. 1 of the Southwestern Miami Development Co. is now 1210 ft. deep and has been in ore for the last 100 ft. The ore has the same general character and appearance as the Live Oak ore and there seems to be no doubt that it is a continuation of the Live Oak orebody. This hole is the deepest hole that has ever been drilled in this district.

At the Superior & Boston a station is being cut in the McGaw shaft at the twelfth level and exploration of the veins by diamond drilling continues. The 1000 gal. Prescott station pump is being moved from the sixth to the twelfth level. A similar pump is stationed on the tenth level and is handling 700,000 gal. of water per day, only a small part of this coming from the shaft. A. C. Stoddard, formerly associated with George Kingdon, superintendent of the Old Dominion, recently was made superintendent of the Superior & Boston, succeeding J. D. Wanvig, who resigned to accept a position with Weed & Probert. W. G. Rice, the president, has just completed a visit of inspection of the mine.

Pumping has been discontinued at the Arizona Commercial and the mine is now entirely idle. Charles S. Smith, president of the Old Dominion, who will be president of the reorganized Arizona Commercial company, recently made a visit to the property and stated that the reorganization would probably not be effected until after the first of the year. The outstanding bonds will have to be foreclosed and the property sold to the new company; and the new company will start with not less than $300,000 in the treasury.

The local management of the National Mining Exploration Co., which formerly operated the Williams and Iron Cap shafts on Copper Hill, states that the National Mining Exploration Co. in bankruptcy will wipe out its local indebtedness this week, and that the deed to the property will be delivered to the Iron Cap Copper Co. not later than December 1, after which the new company will be able to begin work.

Globe, November 23.

Mohave County

Ore assaying $200 per ton has been discovered near Mineral, about three miles south of Chloride, by Christopher Brain, according to recent press reports. The Western Railway of Arizona crosses the land. Brain is now sinking a shaft.

Pima County

Ore assaying as high as $50 per ton has been found in the Sierritas by Lorenzo Boido and R. E. Ballinger of Tucson, according to newspaper reports. Several claims have been filed.

Pinal County

Development is to be resumed at the London-Arizona mines, near Kelvin, in conjunction with the Gila Sulphide mines at Christmas, Gila county. Large deposits of smelting ore assaying about 5% copper have been prospected.

Santa Cruz County

The erection of a tube-mill and cyanide plant at the Huebabi mine, on the Santa Cruz river, soon will be completed. The property is owned by California investors. Large deposits of low-grade gold ore have been developed. The new equipment will give a capacity of 50 tons per day. Epes Randolph is reported to have an option on the Austerlitz property, of which William J. Partridge is manager, the terms providing that Partridge is to retain a quarter interest in addition to receiving $25,000 cash.

Yavapai County

(Special Correspondence.)—The Jerome Oil Co. has been incorporated at Jerome by R. A. Armstrong, T. C. Stone, and W. M. Neagle. Drilling will be started soon on the Duff mesa on the Upper Verde. Mr. Armstrong has gone to Los Angeles to purchase a drilling outfit.

The United Verde Copper Co. has purchased all of the ranches on the Upper Verde near the new smelter site. Work is being rushed on the railroad from Cedar Glade and several miles of grading has been completed. Work on the smelter will not be started for several months. W. A. Clark is now having the specifications prepared.

Prescott, November 25.

CALIFORNIA

Nevada County

The Black Bear mine, in the Moore's Flat part of the Alleghany district, has been reopened by William Gregory and J. C. Lew, who also have secured a bond and lease on the Metropolitan mine, in Grass valley, from the Reynolds estate. They will work the Black Bear in conjunction with the Metropolitan mine. The veins cross at a point 350 ft. from the mouth of the Metropolitan adit.

Shasta County

The smaller of the two smokestacks of the Mammoth smelter is being lowered to the ground. The stack was 150 ft. high and 12 ft. diam., and constructed of steel from $\frac{1}{4}$ to $\frac{1}{2}$ in. thick. The steel will be used in various departments of the smelter and mine, according to reports from Kennett. About 35 tons of steel and 5 tons of rivets were used. The stack is lowered a section at a time after the rivets are chiseled through.

Siskiyou County

(Special Correspondence.)—The River Bend M. Co. has a force of 50 men at work near Walker. The company acquired the Lou Dugget placer property about a year ago and has opened good gravel. A bond has been obtained on the Quigley bar. San Francisco people are interested in the company. The McKinley mine and mill, Yellow Jacket and Sanborn mines, in the Humbug Creek district, have been purchased by J. C. Nash, of Medford, Oregon. It is stated that development will be vigorously conducted. Work has been resumed in the Hunter mine on Prospect hill, Blue Lakes district. A small cyanide plant has been installed, and if developments continue satisfactory a reduction plant will be provided. The vein is reported 32 in. wide with ore assaying $45 per ton up. Some samples gave return of $800. The property has been opened by a long adit and 90-ft. raise. J. A. Hunter is manager. The mill at the Little mine has been remodeled and will go into commission as soon as sufficient water is available. Development is progressing at the mine. C. S. Little is manager. The property is situated on Prospect Hill. Louis McClellan has leased the Del Bondeaux claim and has started preliminary work. The management reports improving conditions at the Cub Bear mine, with development progressing steadily. The vein is 36 in. wide, with ore averaging about $50 per ton. Sixty tons is on the dump. The property is controlled by the Siskiyou Syndicate, and lies in the Salmon River district. James J. O'Connel is superintendent. The same company has developed a 4-ft. vein of ore running over $10. per ton in the Blue Jeans. An 18-in. shoot has also been opened, and is said to assay $150 per ton. Most of the placer mining companies have completed arrangements for the winter season, and with the first rains giants will go into commission on numerous holdings.

Etna, November 24.

The Hazel mine, Tom Salsbury lessee, near Hornbrook, has resumed operation. Recent rains have enabled Salsbury to use five stamps in the mill, which, with the ditches and other equipment, recently was thoroughly overhauled.

Tuolumne County

(Special Correspondence.) A body of remarkably high-grade ore has been developed in the deepest two levels of the New Albany mine, one of the group owned and operated by the United Mines Corporation. The orebody was uncovered some time ago, but the real importance of the mine did not become known on the outside until this week. Long drifts have been driven into the shoot at the 800 and 900-ft. levels and these have proved it to be large and show that the content is well distributed throughout its length. The rich streaks will go high into the hundreds of dollars per ton, and all is high milling grade. The United Mines Corporation, organized under the laws of Colorado, and having a capital stock of $5,000,000, with shares at $1 each, filed articles of incorporation in this county last week. The directors are Howell Hinds, S. M. Bond, R. A. Harmon, W. J. Rattle, Charles Babcock, W. S. Briggs, W. H. Warner, D. R. Taylor, and William C. Eakins.

The botttom of the winze being sunk 500 ft. from the mouth of the adit of the Big Four mine, which was recently bonded to R. E. Edgar of Los Angeles, is in 4 ft. of ore that is estimated to be worth a few hundred dollars per ton. No assays have been made recently, but a shipment of one carload will probably soon be made to determine the exact value of the ore. The property is situated a short distance east of the Dead Horse, near Tuolumne.

C. J. Sullivan and Frank Thomasson plan erecting a cyanide plant before long for treating the tailing and sulphide recently purchased by them from the Soulsby mine.

William Olsen, an old prospector of this district, is developing a 5-ft. vein near the south fork of the Tuolumne river, southeast of here, that promises well. Samples brought in from the property this week show countless flecks of free gold. The Dante Cinelli mine, on the Knapp ranch, near Columbia, has been bonded to E. Greenwood, and some development work is being done. It is reported that the Moccasin Creek Mining Co. contemplates the resumption of operations at its property in the near future.

Tuolumne, November 25.

Yuba County

Reports from Marysville state that Henry Appleby has started suit against the Yuba Con. Goldfields Co. for $50,000 damages. He alleges that he was crippled for life through the starting of the machinery of a dredge at Hammonton while he was engaged in cleaning a cylindrical screen.

COLORADO

Clear Creek County

(Special Correspondence.)—Ritter & Co., operating the P. T. property, have started a new shaft. A small streak of $40 gold-silver ore is being followed. A streak of ore 3 in. wide has been found in the shaft being sunk on the Neptune mine that is worth $300 per ton in gold and silver. The property is being operated by the Investors Mutual M. Co., C. F. Cabeen serving as manager. A 15-hp. whim is being installed at the Gladstone mine. The shaft is down 75 ft. C. L. Jayne is manager. A body of ore 3 ft. wide has been found on the Gem vein, 400 ft. east of the lateral run from the Newhouse adit, that is worth $90 per ton. Claypoole & Hauser have completed their contract of 1500 ft. at the Lucania adit, making the bore 6808 ft. long. L. Sternberger will put a force of men to work at once in driving a lateral east on the J. L. Emerson vein. Arrangements have been made by John Owen, manager of the mine, whereby work will be done in the Specie Payment mine through the Lucania adit. Work is now going ahead through the Two Brothers adit and one carload of ore is being shipped daily. Shipments are going out from the Harrison mine at Freeland, returns of $80 per ton in gold and silver being received in settlement. Charles Williams is manager. Work was resumed last week on the Merry Monarch mine on lower Fall river. J. W. West is manager of the property.

Idaho Springs, November 25.

(Special Correspondence.)—The Capital M. & T. Co. will carry a raise on the Aetna vein from the adit-level to surface, a distance of 1775 ft. This raise is now up 450 ft. E. Bauman is manager. Cavanaugh & Co., leasing in the Peters property on Republican mountain, has penetrated an 8-in. streak of ore that assays about 310 oz. silver per ton. M. Bonham, owner of the North Star property on McClellan mountain, shipped two tons of ore this week that milled $82 per ton in gold and silver. The vein is 6 in. wide and is exposed for 30 ft. It is reported that W. E. Renshaw, of Idaho Springs, will shortly take over the Kelly adit property on Democrat mountain and that he has announced development will be commenced. The Empire T. Co. is making ready to resume work on its property situated on Covode mountain. The adit that has been driven 2500 ft. is to be extended 2000 ft. Work will also be carried forward in the six upper levels of the Gold Dirt mine. A concentrating plant of 200 tons daily capacity is being considered. A. Harley is manager. Shipments have been started from the Eureka mine on Silver mountain. The ore is worth $65 per ton in gold and silver. Development is under way at the Pioneer mine and shipments are going out to the Golden smelter. The ore is worth $70 per ton.

Georgetown, November 25.

GUNNISON COUNTY

Development work, principally sinking the inclined shaft, will be continued throughout the winter at the Italian Mountain mine. Shipment of ore to the Salida smelter is to begin in the near future.

The Doctor mine, at the end of the Italian mountain mineral belt, is shipping ore to the Salida smelter. The ore yields about 30 oz. of silver per ton and 40 to 50% lead, according to press reports.

TELLER COUNTY (CRIPPLE CREEK)

Stratton's Independence, Ltd., has declared a dividend of 10% on its $600,000 worth of stock. This is the second dividend this year and its payment will make the distribution for the year $120,000. The development in the year ended June 30 amounted to 9186 ft., the largest since 1903, when 10,100 ft. of development work was done. The company in this period produced 1752 tons of ore, which had a gross value of $41,889, and a net value of $28,190. In addition to this shipping ore the company produced 7441 tons of low-grade milling ore which had a net value of $9502. The total net profits of the company was $37,692 for the year, against $37,467 for the preceding year.

LOGAN SHAFT, STRATTON'S INDEPENDENCE MINE.

IDAHO

SHOSHONE COUNTY

The Sunset mine, in the Sunset Peak district of the Coeur d'Alene, will be opened upon an extensive scale early next spring by William A. Clark of Butte, Montana. The property has been idle nearly twenty years. It is announced by Mr. Clark that a large force will be put to work when operations begin.

The Bunker Hill & Sullivan Mining & Concentrating Co., operating in the Coeur d'Alene, brought its total disbursements to $13,094,250 by the payment of the 190th dividend of $65,000 for November.

William T. Tracy of Galesburg, Illinois, who recently acquired the Amazon-Manhattan mine in the Sunset district near Wallace, announces that a mill and compressor will be installed as soon as the Washington Water Power Co. completes its transmission line up Nine Mile creek.

Over $2,300,000 has been disbursed among its stockholders to date by the Hecla Mining company, operating in the Coeur d'Alene. The November dividend was $20,000, at the rate of 2c. per share, bringing the total for the 11 months of 1911 to $220,000. The company is said to have sufficient ore blocked out and in sight to maintain its present output for at least five years and has about $250,000 in cash in its treasury. The company is capitalized at $250,000, in 1,000,000 shares of a par value of 25 cents each.

The Federal M. & S. Co. has declared its regular quarterly dividend of $1\frac{3}{4}$c., amounting to $210,000, on $12,000,000 of its preferred stock outstanding. This brings the total for the year to $840,000, and $6,851,250 to date. The last dividend paid on common stock of the Federal company was in January 1909.

MONTANA

LINCOLN COUNTY

(Special Correspondence.) Bringing out with him a gold brick worth about $1000, A. M. Balfour, who is operating the Blacktail mine in the West Fisher district, is in Libby and states that the gold was secured as a result of a few hours' run of the mill. The mill was only run for a short time on account of a cold spell of weather which came on shortly after starting up the machinery, but the brief run proved satisfactory. A small force of men has been at work at this property for several months breaking down ore and getting the stamp-mill in shape to run, and the short test-run that was made convinces the lessees that the property will prove to be a rich one. The mine has produced considerable gold in the past, but has never been extensively developed.

Libby, November 25.

MISSOULA COUNTY

The Success Mining Co. paid a dividend of $15,000 for November, making $60,000 paid so far this year. Another dividend of $15,000 will be paid this year. H. F. Samuels, chief owner and manager of the mine, says the property is in excellent condition, adding that there is ore to last for years above the present working tunnel.

SILVERBOW COUNTY

(Special Correspondence.)—The Butte & Superior company has decided to erect an experimental plant on its property for the purpose of practical tests of the Peterson process of smelting zinc ores. Mr. Peterson, who is a Butte man and a graduate of the School of Mines, claims that he has discovered a method of treating by electricity zinc ores in which the cost will be of minor importance. A. B. Wolvin while in this city recently had several conferences on the question of the use of the process by the Butte & Superior company, with the result that the president of the company decided to give Mr. Peterson a chance to demonstrate in a practical way the practicability of his process. The experimental plant will be constructed at once.

The Consolidated Gold & Sapphire M. Co. has had its patent on the Ruby First placer claim cancelled by the United States Land Office. A protest was filed against the issuance of the patent last summer and a hearing was had which extended over a considerable period of time, the evidence covering 800 pages of typewriting. The receiver of the Land Office reached the conclusion that the protest was justifiable. It was taken on the grounds that the company had not done $500 worth of work and that the land was non-mineral in character. The company had a dredge which was at work on some adjoining property do a lot of work and put this in as evidence to show that the required amount of work had been performed.

The claim against the Basin Reduction Works of about $240,000 which is held by the State Savings Bank of this city, has been redeemed, but just who has advanced the money is yet uncertain. The works were originally owned by F. Augustus Heinze, and nearly one year ago the property was sold at auction and bid in by the bank which held a note for the money loaned. Within a short time W. A. Clark has had experts looking over the property and it is believed that he put up the money. For some time he has been looking over various sites for the purpose of building a zinc smelter, and it seems that he has reached the conclusion that the Basin works could be remodeled and equipped at less expense than the erection of a new building.

Butte, November 24.

NEVADA

CHURCHILL COUNTY

Much of the mine equipment for the Jack Pot, at Wonder, has been ordered and the mill will be erected in the near future. It will be necessary to build about 7600 ft. of transmission line between the property and the power company's line. Among the mine machinery ordered are electrical transformers and material for the sub-station. E. S. Cunningham is superintendent for the company.

Esmeralda County

Stockholders in the Goldfield Silver Pick M. & M. Co. will have until December 16 to exchange their shares for those of the Silver Pick Consolidated Co. recently organized. At that date the stock of the old company will be withdrawn from the San Francisco Stock Exchange. In an official report to the stockholders, A. S. Haskell, of Santa Cruz, stated that the workings of the lease operated by the Golden Pick M. & M. Co. are open and in good condition to, and including, the 250-ft. level. He recommended exploring the property.

Lyon County

The Nevada Douglas Copper Co. recently made its first shipment of gypsum from the property to the Western Gypsum Co. at Reno. The former company is shipping 100 cars per day to the Western Gypsum Co., according to recent press reports. The construction of a spur track is now under way.

Nye County

Shipments from the Tonopah district last week were as follows: Tonopah M. Co., 3300 tons; Belmont, 2550 tons; Montana-Tonopah, 1033 tons; Tonopah Extension, 1008 tons; West End, 525 tons; and Midway, 50 tons of ore. In addition to these shipments of ore, the West End shipped 280 tons of old tailing. The total shipments were 8466 tons, valued at $211,650.

J. S. Austin, president of the Tonopah M. Co., is quoted as saying that the company is considering purchasing the Cain properties at Aurora, as ample cash resources are on hand. The option held on the properties, which originally would have expired December 31, has been extended.

The Tonopah M. Co. mill during last week crushed 3300 tons of ore, of an average value of $20.50, and produced 26 tons of concentrate valued at $13,000. Construction of the Tonopah Belmont continues at a satisfactory rate. The Montana-Tonopah mill crushed 1033 tons of ore.

Lander County

Many prospectors have gone to Carroll on account of reports of valuable ore being found there. The ore is black manganese, and it is asserted that a shipment of 11 tons recently netted $2700. The original discovery was made on a claim owned by Watt brothers, and by them sold to a syndicate of Salt Lake City men headed by E. A. Wall.

Storey County

The report for the year ended November 15 of the work done in the Union Con. mine shows a production of 1069 tons of ore, assaying on the average $10.33 per ton, and having a gross assay-value of $11,054.

The Ophir and the Con. Virginia mines were the only ones to see the customary activity last week. The Ophir produced 380 tons of ore, of which the average value was $53.09. In the Con. Virginia the southwest prospecting drift on the 2550-ft. level was advanced 17 ft. and now is in 317 ft. The face is in low-grade quartz. The pumps were working all week, and last Saturday the water was 295 ft. below the 2350-ft. station. No production for the Con. Virginia was reported. Little mining was done at the Union shaft and other Comstock mines.

Washoe County

The Nevada United M. Co. has started erecting a new 40-ft. head-frame and equipping its property, in the Wedekind district, with modern machinery. Charles L. Roberts, on the Pay Rock claim, has intersected the Conchay vein. Ball & Taylor have secured a lease on the City View claim, which is owned by Bales, Pettigrew & Pratt.

White Pine County

In the Zack shaft of the Ely Con. Copper Co. the miners are working three faces of ore. After many unexpected delays the Veteran mine, according to late reports, is about ready for the resumption of development work. Tests are being made in the concentrator at McGill to ascertain exactly what return is yielded by the concentrate under the present treatment, and to learn of any possible improvement in the method.

NEW MEXICO

Socorro County

(Special Correspondence.)—The October bullion production of the Socorro mines was about 35,000 oz. gold and silver, with 10 tons of high-grade concentrate, from an ore-treatment of 4400 tons. Good progress is being made on the new power-plant. Work in the lower levels of the Deadwood mines is being pushed. The mill is handling a good tonnage, partly custom ore.

A contract has been let by the Alberta M. Co. to drive 50 ft. on the vein in the Independence Jr. mine.

Most of the heavy machinery for the new power-plant of the Ernestine M. Co. has been delivered. The new 10-stamp battery is nearing completion. The bullion product for the first 10 days of November was 7610 oz.; concentrate, 9200 lb. The ore treated the past two weeks amounted to 1382 tons, yielding 115 sacks concentrate, in addition to precipitate.

A development adit was started on the vein on the Pacific mine of the Oaks Co. The South shaft has been timbered and is in readiness for breaking ore. The north working shaft was sunk 6 ft. during the week. The Treasure M. & R. Co. added two more ore-teams during the week, increasing the regular delivery to 80 tons per day.

An average of 10 tons of ore per day from the Little Charlie mine of the Mogollon Gold & Copper Co. is being delivered to the Deadwood mill. Contractors are steadily advancing the 200-ft. level west of the Trilby group.

Mogollon, November 24.

UTAH

Juab County

After a temporary shut-down, the Utah Con. M. Co. has resumed operation. William Mathews is superintendent of the property.

Work is progressing well in the prospecting drift from the main adit of the Uncle Sam mine. This drift, which runs south, is developing the ground of the Richmond & Anaconda company, of which four-fifths is owned by the Uncle Sam company. The Eureka Comstock, in the North Tintic district, will resume sinking the shaft, which now is 50 ft. deep. James Larson is manager of the property. The Grand Central last week made lighter shipments, but the ore was more valuable than usual.

Summit County

The Daly-Judge M. Co. has declared dividend No. 3, for the quarter ending December 31 and payable December 20, of 15%, which will require the distribution of $45,000. An official announcement has been made that this rate of quarterly dividends will be maintained in the future. With the announcement is a statement for the eight months ended October 31, showing that during that period the company produced 32,278 tons of concentrating ore and 5495 tons of shipping ore. The company sold 7870 tons of lead concentrate and 2385 tons of zinc concentrate. No zinc concentrate has been sold since September. The monthly averages for the eight months are as follows: shipping ore, 687 tons at $27.51; lead concentrate, 984 tons at $27.47; zinc concentrate, 340 tons at $11.06; development expenditures, $8287; mining cost, $3.55 per ton; milling cost, 80c. per ton; earnings, $16,032. The average earnings for the last three months were $23,630 per month. There was an available balance of $421,235 on November 1.

Tooele County

The Utah Con. Copper Co. has maintained shipments averaging 600 tons of ore per day to the International smelter at Tooele from the deposits in Salt Lake county, since November 1, according to a recent statement by E. P. Mathewson, general manager for the International S. & R. Co. Mr. Mathewson last week spent three days at the smelter and after the inspection said that the lead smelter should be in commission soon after January 1. He expressed gratification at the work done at the smelter.

WASHINGTON

Ferry County

Frank Ansley, manager of the White Elephant mine in the Orient district, says that a mill will be installed next spring.

The North Washington Power & Reduction Co. is erecting a pulp thickener for its mill, also a 325 hp. engine, three boilers, and a 225 kw. generator for the power plant, at its property at Republic.

(Special Correspondence.)—The Republic Mines Corporation has constructed an incline tramway, for the purpose of raising ore from the top of the main inclined shaft to a Great Northern railway spur, at a considerably higher elevation, and a switch has been put in at the Spokane & British Columbia railway depot for transferring the ore cars to the Spokane Falls & Northern railway track and facilitating shipments. Retaining walls are under construction for an auxiliary compressor plant, and a new 12 by 12-in. cylinder Ingersoll-Rand compressor, to be driven by a 75-hp. electric motor, is being placed, for reinforcing the power already in use. A smaller hoist at the main shaft has been replaced by a 6 by 8-in. double-cylinder hoist, good for 800-ft. depth. Development has been resumed.

At the Knob Hill mine a stope is being opened on the No. 3 level, at a vertical depth of 280 ft. on a pay-shoot 5½ to 6 ft. wide, the ore averaging about $30 per ton. The ore shipments are maintained at the usual rate of five to six carloads, being from 250 to 300 tons per week, all that the Trail, B. C. smelter will take.

At the Black Tail mine operations are now confined to the 300-ft. level, where a B. C. 11 Ingersoll-Rand drill is in commission on a lateral vein of 3 to 8 ft. in width.

The Gold Ledge Mining Co. has been organized by C. F. Crum, of Spokane, Washington; A. A. Booth, consulting engineer for the Hecla Mining Co., at Burke, Idaho; and John Cochrane, of Modesto, California.

Republic, November 25.

Stevens County

(Special Correspondence.)—The British Columbia Copper Co. is about to add a filter-press to the equipment of the mill for the Napoleon mine, situated between Marcus and Orient.

Orient, November 25.

WYOMING

Uinta County

At a public sale J. W. F. Volker, of Ogden, Utah, bought the Elk Coal Co. at Evanston. The company owns 2000 acres of land, eight miles of railroad which connects Elkol, the company road, with the main line, a telephone line, a church, 40 residences, a school house, a store, and complete mine equipment. The winning bid, presented by Mr. Volker, was $245,000.

CANADA

(Special Correspondence.)—The iron and steel interests are agitating for increased protection. This week a strong deputation representing the leading mills and furnaces waited on the Government with the request that it consider the claims of the industry for an increase in the tariff and in the meantime, as a temporary expedient, renew the bounty on pig iron. The Government has declared in favor of appointing a permanent Tariff Commission to report upon all questions of tariff changes, so that it is hardly likely that anything will be done in the way of increasing duties before that body is constituted. It is not unlikely, however, in view of the recent political change, that the pig-iron bounty may be restored.

Toronto, November 23.

British Columbia

(Special Correspondence.)—The British Columbia coal strike has at last been settled and the mines reopened, but probably too late to prevent widespread distress and calamity in the province of Saskatchewan, owing to fuel shortage. It is stated that stocks in the hands of local dealers are exhausted and settlers unable to obtain their winter's supply. The Canadian Government, which temporarily removed the duty to enable the West to procure coal from the American mines, has re-imposed the duty from December 6, although the situation continues extremely serious.

Greenwood, November 25.

The annual report of the Red Cliff M. Co., in the Portland Canal district, states that during the preceding eleven months 2100 ft. of development work was done. Of this work 1680 ft. was done since April. It is stated that several orebodies have been found.

Ontario

(Special Correspondence.)—Cobalt ore shipments show a steady decrease in tonnage, the figures for the first ten months of the year being 21,370 tons, as against 36,125 for the first ten months of 1910. As has been previously explained, this does not indicate a decreased silver output, as an increasing proportion of the ore mined leaves the camp in the form of silver bullion or concentrate. The La Rose Consolidated has lately considerably improved its position by new finds. An ore-shoot 6 in. wide and stated to run 5000 oz. per ton, has been found in cross-cutting on the Lawson half way up the stope from the 180-ft. level on vein No. 8. At the Princess a 2-in. vein of low grade has been cut at the 100-ft. level, and a good find consisting of a 12-in. quartz and calcite vein carrying native silver has been made on the Fisher-Eplett property. This will be sunk on immediately. The City of Cobalt has leased the King Edward concentrator at Cross Lake for the treatment of its low-grade ore. The Cobalt Lake has picked up the Cobalt vein worked some years ago at about 100 ft. from the shaft at the 160-ft. level. It runs about 200 oz. silver per ton, and large shipments are being made. The mill is running steadily, treating about 75 tons per day. The Coniagas has paid its fourth dividend for the year, of 6%, with an additional 3% bonus.

M'KINLEY-DARRAGH SHAFT IN 1908.

Toronto, November 11.

The McKinley-Darragh-Savage mines of Cobalt have declared a dividend of 10%, payable January 1. The last dividend was paid October 1. The dividend just declared will bring the disbursements to stockholders up to $2,156,521.

Yukon

The Yukon Gold Co. shut down its last dredge for the season on November 3. The Canadian-Klondyke M. Co. still is operating two dredges on the Boyle concession, and will run as long as possible. Last year the company operated until December 12. The other dredging companies are reported to have stopped operating some time ago.

MEXICO

Chihuahua

At the Adela mine, in the Roncesvalles district, mining is to be resumed on a larger scale than ever before. Work was stopped several months ago owing to the depredations of bandits in the district, but the outlaws have been suppressed by the authorities. I. E. Van Dreveldt is manager of the property.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press.

Failure to Discover Ore in Mining Discovery Shaft

The failure to discover ore in a discovery shaft sunk on a mining claim does not affect the validity of the claim or the claimant's title, where the locator subsequently found valuable ore in other workings on the claim, and where the work done in other parts of the claim where ore was unquestionably discovered was more than the equivalent of that required by the discovery shaft.

Gibson *v.* Hjul, (Nevada) 108 Pacific, 759.

Lease of Mine—Payment of Rent

At the time of making the lease of mines the lessee deposited money with the lessor as an advance payment of certain sums to become due from time to time by the terms of the lease; and the lessor could not sue the lessee to recover any sums due under the lease while a sufficient amount of such deposit remained in his hands to pay the amount due.

Patton *v.* Hamilton Coal & Mercantile Co., (Kansas) 107 Pacific, 764.

Injury to Miner by Falling Rock—Liability of Mine Operator

In an action for the death of a miner who was killed by falling rock from the roof of a tunnel, it was held competent to show that rock and earth had fallen from the roof at different times prior to the accident and at other places, for the purpose of showing the character of the ground and the necessity of supporting the roof, and as a means of conveying notice to the mine-owner and operator to the defective and dangerous condition of the roof.

Sargent *v.* Union Fuel Co., (Utah) 108 Pacific, 928.

Taxation of Mining Claims—Description of Claims

The statute of Arizona provides that the assessor in preparing an assessment roll shall describe real estate by common designation or name, and it also provides that the description shall be sufficient if the land or premises can be readily identified thereby. Under this statute the Supreme Court of Arizona held that the description of a patented mining claim was sufficient, as the name of such claim was a "common designation or name" within the meaning of the statute, and that by such name the premises might be "readily identified." The court also suggested that the practice of assessing patented mines by name has obtained too long in the territory to be questioned, and that such practice is a practical construction of the statute as the mode of assessment, and of which the courts may take judicial notice.

Territory *v.* Copper Queen Consolidated Mining Co., (Arizona) 108 Pacific, 960.

Care Required of Operator of Mine

An operator of a mine must use such care for the protection of the miners as would be exercised by an ordinarily prudent man in the same business, and he must observe the same rules in selecting the tools and appliances furnished the miners. Accordingly, where the operator of the mine selects an appliance in general use and reasonably adapted to the purpose for which it is used, a mere continuance of its use does not of itself indicate negligence, though there may be safer devices used by other operators to accomplish the same purpose. When an appliance is not obviously dangerous, but has been proved by long use to be safe and efficient, its use may be continued. An operator of a mine, like other employers, is not required to furnish the best appliances nor the safest, nor provide the best method for the operation, as such a rule might require a continued change of appliances and tools.

Cummings *v.* Reins Copper Co., (Montana) 107 Pacific, 904.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the Mining and Scientific Press.

Illustrated Guide to the Malay States. By C. W. Harrison. 333 pp. Ill., map. The Malay States Information Agency, London, 1911. For sale by the *Mining and Scientific Press*. Price $1.50.

This little volume, of pocket size, is not an ordinary guide book, though it will serve excellently for that purpose. The first chapter, over one-third of the book, is devoted to a description of the ethnology, geography, history, and present condition of the Malay States. Like the rest of the book, it is beautifully illustrated with halftones and plates in color, and will prove interesting reading even to one who has no intention of visiting the country. Chapters devoted especially to hints for travelers and motorists follow, and big game shooting has a chapter to itself. The mining industry, which is of so great importance to these States, is well treated at some length, and a chapter of tariffs, distances, and weights and measures completes the book. As a means of disseminating interesting and accurate information regarding the Malay States the book is a conspicuous success.

The Lay-Out, Design, and Construction of Chemical and Metallurgical Plants. By Oskar Nagel. 201 pp. Ill. Published by the author, New York, 1911. For sale by the *Mining and Scientific Press*. Price $2.

Opinions as to the excellence of this book are likely to vary widely, according to the purpose for which it is read. The scope of the book is wide, and the manner of treatment is somewhat popular, giving the impression that the subject matter is a compilation of descriptions which have appeared in technical journels. To one who wishes to acquire a general knowledge of methods of procedure in various lines of industry this will be most interesting and useful, and engineers will find much that is suggestive in the descriptions of plant designs for widely different types of industry. The limitations of the book are well exhibited in the chapter on the design of copper smelting plants, that topic being covered by a single paragraph of fifty words illustrated by two drawings. Similarly, the design of cyanide plants is covered by a description of the 600-ton plant of the Goldfield Consolidated which, though excellent, scarcely embodies all the principles of cyanide plant construction. Plants for chemical industries, such as sugar and alcohol making, and for peat and brickmaking, are described at some length.

Handbook of Steam-Shovel Work. Pp. 374. Ill. The Bucyrus Company, Milwaukee, 1911. For sale by the *Mining and Scientific Press*. Price $1.50.

This excellent compendium of steam-shovel practice was prepared by the Construction Service Co., chiefly by Messrs. R. T. Dana, F. M. Gaiger, Charles Houston, E. C. Wilder, A. C. Haskell, and W. T. Ball. The first four chapters are general and deal with the nature of excavation work and its problems, the general conditions and formulas, field conditions of work, and the estimating of excavations. The following chapters discuss in detail forty-five examples of steam-shovel work, handling sand, earth, glacial drift, clay, and iron ore. The information, especially regarding operation and costs, contained in these reports, is of the greatest value, and it is to be regretted that examples of the excellent work being done in the mining of copper ore and in the handling of earth and rock on the Panama canal were not included, especially since the records for capacity and cost are being made in these two places. But, as it is, the book is a veritable mine of information, and will be of the greatest interest to all engineers who are concerned with the handling of material. The usefulness of the book is greatly decreased by that common error of inexperienced authors and editors, the omission of a full and complete index. In spite of this defect, this little volume is likely to be widely appreciated.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. H. **Aldridge** is in Arizona.

Albion S. Howe is at Miramor, Costa Rica.

Malcolm Maclaren is at Plymouth, California.

Willis Lawrence has returned from Nevada City.

Charles W. Wright is at Genoa for a short stay.

Pope Yeatman is on his way to Ely and Salt Lake City.

E. P. **Mathewson** has been at Tooele, Utah, for a few days.

Charles F. Spaulding has returned to Denver from Parral.

Corridon H. Putnam was in San Francisco early in the week.

F. L. **Sizer** has gone to Idaho and Montana on professional business.

Edmund Juessen was at Blair recently and has returned to San Francisco.

Philip Argall, general manager of Stratton's Independence, is in London.

W. S. **Noyes** is at Shafter, Texas, expecting to return in about two weeks.

D'Arcy Weatherbe will be in London in December from St. Petersburg.

C. W. **Purington** announces that his St. Petersburg office is at 42 Moika.

R. H. **Chapman** has returned from Vancouver and has gone to Washington, D. C.

Theodore L. Lammers has gone to Alaska to examine mining property near Valdez.

E. J. **Schrader** has been confined for six weeks at St. Joseph's hospital, Nogales, Arizona.

F. F. **Kett** has gone to Nora, Sweden, as general manager for the Swedish Iron Mines & Furnaces, Ltd.

Frank Healy, of the Nevada Wonder Mining Co., is in San Francisco recovering from a nervous breakdown.

A. W. **Kean** left Birmingham, England, recently, to be with the Sefwhi Goldfields, Ltd., at Dunkwa, West Africa.

E. R. **Buckley** has engaged in practice as a consulting mining geologist, with offices at 1364 People's Gas building, Chicago.

George Schroter is in Mexico on a regular trip of inspection of the various properties of the Mines Company of America.

E. H. **Harrington** has resigned as superintendent of the Bunker Hill, in Amador county, and will be succeeded by **Elisha Hampton**.

Emile Huguenin has returned to San Francisco, having left Minas Pedrazzini, Arizpe, Sonora, Mexico, on account of labor trouble, causing a general shut-down.

J. M. **Leaver**, general manager for the Pearson company at El Paso, has resigned his position, and will devote his time to his manufacturing interests in Los Angeles.

D. L. H. **Forbes** has moved his office to 306 Manning Chambers, 72 Queen W., Toronto, Ontario, where he will practise mining and metallurgical engineering on behalf of the Merrill Metallurgical Co. of San Francisco.

James Douglas delivered an illustrated lecture on 'The Development of the Copper Queen and the Warren Mining District' at a special general meeting of the Institution of Mining and Metallurgy, on November 23 in London.

J. W. D. **Moodie** has resigned the position of general manager for the Yampa Smelting Co., and has accepted the position of general manager for the Britannia Copper Syndicate, Ltd., at Britannia Beach, British Columbia. D. F. **Sheehan**, formerly with the Copper Queen company, will succeed Mr. Moodie at the Yampa.

Manganese ox., blk., Caucasian, in casks, ton (85% MNO_2—¾% Fe)	42.50	50.00
Nitre, double ref'd, small cryst., bbl., 100 lb.	7.00	8.00
Nitre, double ref'd, granular, bbl., 100 lb.	6.50	7.50
Nitre, double ref'd, powdered, bbl., 100 lb.	7.25	18.00
Potassium bicarbonate, cryst., 100 lb.	12.00	15.00
Potassium carbonate, calcined, 100 lb.	15.00	18.00
Potassium permanganate, drum, lb.	0.11	0.12½
Silica, powdered, bags, lb.	0.03	0.05
Soda, carbonate (ash), bbl., 100 lb.	1.50	1.75
Soda, bicarbonate, bbl., 100 lb.	2.00	2.50
Soda, caustic, ground, 98%, bbl., 100 lb.	3.15	3.50
Soda, caustic, solid, 98%, drums, 100 lb.	2.65	2.85
Zinc shavings, 850 fine, bbl., 100 lb.	11.25	12.00
Zinc sheet, No. 9—18 by 84, drum, 100 lb.	9.75	10.75

Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked*.

	Min.	Max.
Antimony ore, 50%, per ton	*$20.00	$25.00
Arsenic, white, refined, per lb.	0.02	0.02½
Arsenic, red, refined, per lb.	0.07¼	0.08¼
Asbestos, according to length and quality of fibre, per ton	100.00	350.00
Asbestos, lower grades, per ton	10.00	100.00
Asphaltum, refined, per ton	15.00	20.00
Barium carbonate, precipitated, per ton	42.50	45.00
Barium chloride, commercial, per ton	37.50	42.50
Barium sulphate (barytes), prepared, ton	20.00	30.00
Bismuth ore, 10% upward, per ton	*75.00	upward
Chrome ore, according to quality, per ton	10.00	12.50
China clay, levigated, per ton	15.00	20.00
Cobalt metal, refined, f.o.b. London, per lb.	2.50	
Coke, foundry, per 2240 lb.	15.00	17.50
Diamonds:		
Borts, according to size and quality, per carat	2.00	15.00
Carbons, according to size and quality, per carat	75.00	100.00
Feldspar, per ton	5.00	25.00
Firebrick:		
Bauxite, per M	175.00	
Magnesite, per M	190.00	275.00
Silica, per M	42.50	47.50
Flint pebbles for tube-mills, per 2240 lb.	15.00	25.00
Fluorspar, per ton	10.00	15.00
Fullers earth, according to quality, per ton	20.00	30.00
Gilsonite, per ton	35.00	40.00
Graphite:		
Amorphous, per lb.	0.01½	0.02½
Crystalline, per lb.	0.04	0.13
Gypsum, per ton	7.50	10.00
Infusorial earth, per ton	10.00	15.00
Magnesite, crude, per ton	7.50	10.00
Magnesite, dead calcined, per ton	22.50	27.50
Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, per ton	10.00	25.00
Manganese, prepared, according to quality, per ton	30.00	70.00
Mica, according to size and quality, per lb.	0.05	0.30
Molybdenite, 95% MoS_2, per ton	400.00	500.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb.	0.45	0.60
Ochre, extra strength, levigated, per 100 lb.	2.25	3.25
Platinum, native, crude, per oz.	30.00	40.00
Sulphur, crude, per ton	15.00	25.00
Sulphur, powdered, per ton	40.00	45.00
Talc, prepared, according to quality, per ton.	20.00	50.00
Tin ore, 60%, per ton	450.00	475.00
Tungsten ore, 65%	455.00	520.00
Vanadium ore, 15%, per ton	150.00	180.00
Vanadium ore, 15%, per ton	200.00	250.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	*15.00	20.00

Commercial Paragraphs

THE THIOGEN PROCESS for the elimination of sulphur dioxide from smelter fumes has been adopted by the Penn Mining Co. at the Campo Seco smelter, and negotiations have been completed for its installation. This process was described in detail in the *Mining and Scientific Press* of September 23, 1911, by Stewart W. Young.

Various types of mine pumps are required for different conditions of service. Two of recent design, built by THE DEANE STEAM PUMP CO., of Holyoke, Massachusetts, are high-efficiency machines, direct connected by single reduction of gears to moderate-speed motors, and making in either case a very compact, yet wholly accessible arrangement. The construction is necessarily heavy, as continuity of service is the most important item of all. Similar parts are all made exact duplicates, and there are no rights and lefts to introduce confusion in the substitution of new parts. Individual valve-pots with swing bolts for the covers allow quick access to the valves. The horizontal machine is a 3¾ by 12-in. double-acting triplex outside-packed plunger pump, connected by single reduction of spur gears to a 125-hp. Westinghouse induction motor. The motor runs 495 r.p.m., the pump 53 r.p.m., and delivers 175 gal. per minute against 2000-ft. head. The water end is made of steel castings. This unit was built for the Sunnyside mine of the Utah Fuel Co. The vertical pump is one of a pair of 7 by 10-in. triplex, single-acting, built for the Cleveland Cliffs Iron Co. Each is to be driven by a 50-hp. General Electric induction motor through a single reduction of herringbone gears, which make a smooth, quiet-running combination of high efficiency. The motor runs 490 r.p.m. Each unit delivers 300 gal. per minute against 400-ft. head. Either of these pumps, as shown by careful tests, will give an efficiency of 85% under actual working conditions; and, with proper care, the efficiency can be maintained without the gradual falling off that occurs in some other types.

EDITORIAL

APPRECIATION of copper shares has been the natural result of the increased price of copper, and the market shows a firmer tone.

RICH gold deposits in the Assuan region are the objective of the Star of Egypt Mines Company, Limited, recently organized in London. Strange to say, it has not yet been claimed that these are the mines of Ophir.

AN excellent type of skip is described elsewhere in this issue. It was designed by Mr. Willis Lawrence for use at the Florence mine at Goldfield, while manager for that company. It is unfortunate indeed that this issue must also chronicle the total destruction of the Florence mill by fire, early in the week.

AUSTRALIA possesses large unsettled areas in its Northern Territory, and during the present year several parties have been sent out by the Government to explore that little known area. It is not probable that all the important mineral areas of Australia have yet been discovered, and it is to be hoped that the explorations now in progress will be fruitful of result.

THE part which Great Britain played in the recent Moroccan negotiations was recently analyzed by Earl Grey, and the fact was disclosed that the situation was more serious than was generally supposed earlier. The action of the foreign secretary in the crisis has been unsatisfactory to the radical element in the ruling party, and it is not impossible that they may be able to bring about his retirement, as Mr. James Bryce has already been suggested as a possible successor.

IN our 'Discussion' column this week Mr. W. H. Storms outlines plans for the work of the State Mining Bureau and urges that all members of the mining fraternity in California give steadfast support to the Bureau. We heartily second Mr. Storms' appeal. The Bureau is for the purpose of serving the best interests of those engaged in the mineral industry. By their cordial support, generous aid, and intelligent sympathy and interest they can make it of the highest possible service, by their neglect they can render its efforts of little avail. Boost, gentlemen.

CONDITIONS in China continue much disturbed, the latest occurrence of note being the abdication of the Prince Regent and the appointment of a Manchu prince and a Chinese statesman as joint guardians of the throne. Apparently Yuan Shih-kai is practically in supreme command of the central government and appears to be making good progress in subduing the rebellion. Internationally the situation is serious, though little of this appears in the daily journals, as strict diplomatic secrecy is observed. It is fortunate for the United States that its interests are in such capable hands as those of Mr. William J. Calhoun, our Minister to China, who is ably aided by experienced men in Chinese affairs.

INVESTMENTS, whether in gold mines or in corner groceries, possess perpetual interest. Elsewhere in this issue Mr. Morton Webber discusses gold mines as investments in a way that is novel and original. The matter may be regarded from other viewpoints, however, and not every investor will acquiesce in designating as a "blessing in disguise" a method of management which conserves dividends, in the fear that he may unwisely spend them. Mr. Webber's contribution is provocative of thought, and we hope many of our readers will be stimulated to discuss the matter further.

MUCH interest has been aroused by the recent acquisition of control in the Live Oak Development Company by Mr. J. D. Ryan of the Amalgamated Copper Company, and the suggested possibility of the inclusion of the Inspiration Copper Company. Various constructions are put upon the significance of such a move, but, on the whole, it looks very much as if "those who came to scoff remained to pray," and that an initial disbelief in the real importance of large bodies of low-grade disseminated copper ores has altered into a desire to secure a prominent place in this field before it is too late.

SUPREME COURT decision, at Washington, affirming the decision of the Circuit Court in the case of the Stracey coal land claims in Alaska definitely establishes the principle that power of attorney locations of mineral lands are invalid. On the other hand, Mr. Walter L. Fisher, Secretary of the Interior, is evidently bent upon constructive legislation which will lend itself to proper development. His address at Chicago before the American Mining Congress, given in abstract in these columns recently, has been published in full as Bulletin 36 of the Bureau of Mines. It is accompanied by an excellent map showing the mineral resources of Alaska, and both as a source of accurate information and as an authoritative pronouncement of a wise and definite policy, is a notable publication.

CRIPPLE CREEK, at least, had cause for Thanksgiving this year. The greatly increased flow of water developed last month in the deep-drainage adit, known as the Roosevelt tunnel, appears to be persistent, and by December 1, the flow from the mouth of the adit was 8500 gallons per minute. From the south drift on the C. K. & N. vein a flow of 3500 gallons per minute is obtained, and an additional 2000 gallons per minute from the north drift. This corresponds to a rate of recession of the water-level of 4½ inches per day. During November the advance of the main heading, 245 feet for the month, was the highest yet obtained. The growing effectiveness of the drainage adit is most encouraging, deep-level development in the district will be stimulated, and the outlook for next year is correspondingly bright.

SPOKANE members of the American Institute of Mining Engineers have formed a local section, with Mr. R. S. McCaffrey as chairman, and interesting papers by Messrs. H. W. Newton and C. A. Stewart were read at the initial meeting. The rapidity with which local sections of the Institute have been organized is evidence of the service which they can be made to render, and it is to be hoped that wherever a sufficient number of members can be gathered together, sections will be formed and frequent meetings held. The technical discussions are of the greatest service both in crystallizing the ideas of the participants and in obtaining an accurate perspective in viewing a subject, and the usefulness of any paper is greatly increased by thoughtful discussion of its subject matter. Much good, both to individuals and to the profession, should result from sectional meetings, properly conducted.

DECORATION of Messrs. Rossiter W. Raymond and G. F. Kunz with the Order of the Rising Sun by the Emperor of Japan, is worthy recognition of distinguished and honorable professional careers and another token of the high esteem in which the Japanese hold scientific and professional work. It was a particularly gracious courtesy to present the decorations during the visit of the American Institute of Mining Engineers. As our representative with the party relates in another column, every possible arrangement has been made for the comfort and pleasure of the visitors, and the Japanese evidently feel keenly that mutual acquaintance is the best possible basis for good understanding between nations. The party returned to San Francisco on the *Siberia* on Thursday, enthusiastic over the reception which they had received in the land of chrysanthemums, and next week we shall describe at more length the events of their journey.

The President's Message

The annual message of the President to Congress was read before that body on Tuesday. Like most such messages, it is lengthy, even prolix, and the average citizen is likely to content himself with a perusal of the abstract of the document which the daily journals are usually kind enough to provide. But the difficulty with an abstract is always that in selecting which portions to omit and which to retain, the abstractor is guided by his own opinions or prejudices, and is thus enabled to produce an abstract either progressive or reactionary in tone from a message that may be neither. In this case the document is entirely devoted to the question of large corporations and the Sherman law, and following the recent pronouncement of Mr. Theodore Roosevelt upon the same topic, is of great interest. Mr. Taft is an enthusiastic supporter of the Sherman law, which was passed over twenty years ago, lay in abeyance for a long time, and has only comparatively recently proved an effective instrument in the control of large aggregations of capital, and he is opposed to any attempt to secure its amendment. Progress in industry during the past twenty years has been revolutionary, and that a law framed at that time by men who doubtless only imperfectly understood the problems involved, is the best possible law to meet present conditions is remarkable, if true. Nor would the final result in the case of the American Tobacco Company seem to be as effective as Mr. Taft regards it. Court orders to a corporation to dissolve into fragments and to the fragments to compete with each other are academic triumphs, but industrial futilities. The essence of competition is lack of information, information as to cost of raw material, methods of manufacture and sale, and selling costs and prices. This is the kind of competition that is effective as an economic factor, and it is idle to suppose that the dissolution of the American Tobacco Company into a smaller new company of the same name, Liggett & Myers Tobacco Company, P. Lorillard Company, R. J. Reynolds Tobacco Company, and others, will be effective in restoring this kind of competition. The organization of enterprises into single large units commonly known as trusts, is for a variety of purposes, among which is the securing of the economy of large-scale operation and the exchange of information which leads to the elimination of competition in the true economic sense. Dissolving a large 'trust' into smaller units removes the economy of large-scale operation, but has little effect on the interchange of information, and what result can accrue beyond a slight increase in production and selling costs, is difficult to see. It appears very much as if, in the Tobacco case, the shadow had been secured, but not the substance. In following such a line of supposed progress as this we are only getting farther into the bushes, the way does not be in that direction. In economics 2 + 2 + 2 differs as little from 6 as it does in mathematics. When it is clearly recognized that a large corporation which controls the production of any of the necessities of life and thereby draws support from every consumer is therefore rightfully subject to the scrutiny of the great body of consumers as to its conduct of business and the profits which it secures, a notable step in advance will be made. This is already recognized in the case of life insurance corporations, but the principle is of universal applicability and with its general recognition will come a readjustment of relations that will result in new methods of business conduct and great good to society as a whole. But meanwhile, we suppose, corporations will for awhile continue to be subjected to the 'slicing process,' while the stock market performs arpeggios and speculators rejoice.

Enemies of Society

War news from China, Tripoli, and Persia was entirely overshadowed at the close of last week by the announcement that J. J. and J. B. McNamara, then on trial at Los Angeles for the dynamiting of the *Times* building and the Llewellyn Iron Works, would plead guilty to the charges and throw themselves upon the clemency of the court. For the benefit of our many readers who, on mountain and in mine, are engaged in the search for the treasures of Nature and give little heed to the far-away doings of men, it will be useful to briefly review the history of the case.

The *Times* is a well known daily journal, published in Los Angeles by Mr. H. G. Otis, who is perhaps even more widely known for his opposition to labor unions and union labor, an opposition in which he frequently exhibited more zeal than discretion. On October 1, 1910, the *Times* building was destroyed by the explosion of a bomb, and twenty-one men were killed. Suspicion immediately was directed toward labor union members, and inquiries were pursued so successfully that on April 12, 1910, J. B. McNamara and O. E. McManigal were arrested in Detroit and ten days later J. J. McNamara, who is secretary of the International Association of Bridge and Structural Iron Workers, was arrested in Indianapolis. The three were taken to Los Angeles, where McManigal made a sworn statement before the Grand Jury to the effect that J. B. McNamara dynamited the *Times*, while he himself had dynamited the Llewellyn Iron Works, on December 25, 1910. Indictments were returned, and the trial of James B. McNamara finally began on October 11. On December 1 the announcement was made that both McNamaras would confess, as a result of the discovery of the bribing of three of the jurors by the defense. On December 5, J. J. McNamara was sentenced to fourteen years' imprisonment and J. B. McNamara to imprisonment for life.

So far as these men are concerned this ends the case, but, so far as society is concerned, it is only really begun. Many important points are as yet undecided. In the past five years buildings and other steel structures erected by non-union workmen have been subjected to attempts at destruction by dynamite, the total number thus injured being greater than is generally supposed. It is inconceivable that all these cases have been due to the private initiative of desperate men, and the confession of the secretary of a steel-workers' union to having procured the destruction of a non-union iron works opens a field for an inquiry vitally concerning the security and safety of society as a whole. Another phase of the matter is that Mr. Clarence Darrow, a widely known and respected attorney who has been prominent in trials where the interests of laboring men are involved, who conducted the defense of the accused men, appears to have been cognizant of their guilt from the beginning, and yet was a party to the creation of a defense fund by assessing every member of labor unions throughout this country and Canada. For this insult to, or, more accurately, crime against every honest workingman, Mr. Darrow now stands discredited in the eyes of the world.

So much regarding this matter is not yet clearly understood that it is unsafe to generalize as yet. But one feature is brilliantly clear. This is not a case of labor against capital, of workingmen against corporations, it is a case of the people against enemies of the people. We have often referred to the tendency in the development of modern society toward the agglomeration of units. This is a concomitant of evolution, and is well exhibited in the physical world, where from simple one celled organisms evolution has built up the multi cellular, complex, highly specialized organisms, such as the higher types of plants and animals. Similarly men, from action as individuals have developed group action, with as beneficial results as in the development of plant and animal life. Labor unions, corporations, and the many other forms of aggregate activity are evidences of development therefore, only their activities must be properly directed so as to obtain the maximum of benefit. It is not our purpose to discuss here the advantages and disadvantages accruing from this development, other than to refer briefly to the most important of the latter. And that is the obscuring of the bad unit in the larger aggregation of units. This is recognized in the common saying that "corporations have no souls," and constitutes a real menace to society. Labor unions are both desirable and necessary to secure the interests of workingmen. Corporations are necessary and desirable in order to conduct business in accordance with modern development. But a scoundrel and thug is no less a scoundrel and thug, whether he be an officer of a corporation or labor union, or a human wreck, skulking in some dark alley. Society asserts its right to protect itself against such men. The silly talk of magazine paragraphers that these actions are evidences of a class war is wicked in its inherent folly and its appeal to unreason. Crime is crime, and universally recognized as an injury to the interests of society, whether it exhibit itself in smashing the skull of a late way-farer for the few dollars in his pockets, in dynamiting a non-union building, or in ruining a competitor by methods less obviously criminal, but no less so in fact. And society must be rid of crime, to protect itself. It is idle to say that crime is necessary to procure good ends. Men organize into political parties to advance what they conceive to be their best interests, and find it quite unnecessary to poison the opposition candidate or to blow up the convention hall. We are making but slow apparent progress in the solution of social problems because these problems are new and difficult, but we are making progress, nevertheless, though not by the use of criminal means. Crime can no more tend to good ends than grapes can be grown by the use of gunpowder. The mistake lies in allowing the criminal laborer to be identified wiith the cause of labor and the criminal capitalist with the development of big business. Unremitting watchfulness is necessary, for the unscrupulous man naturally is enabled to make himself prominent, being free from ordinary restrictions. It is perfectly safe to say that not only the majority but nearly all workingmen are naturally honest and industrious and contain just as much human nature to the square inch as the average of society. They should be the first to recognize the fact that leaders such as these are enemies of society as a whole, and of workingmen in particular. In the physical organism bad cells, if let alone, give rise to a cancer that destroys the whole. The only salvation is to use the knife freely. And that is the present need of society; cut out the rotten spots, whether they are found in Wall Street, in labor councils, or in dens of infamy.

Marysville Dredge No. 4

By Robert E. Cranston

Editorial Introduction

The Marysville Dredging Co. began operations in 1905 under the direction of R. E. Cranston, who is at present consulting engineer for the company. The property of the company joins that of the Yuba Consolidated Gold Fields on the west and comprises about 1200 acres, of which about one-half is dredging ground. The Yuba Consolidated company owns about 3000 acres of dredging ground. The gravel of both is similar in character and averages about 60 ft. in depth. The depth is due to the tailing from the extensive hydraulic mining which formerly was carried on for years along the headwaters of the Yuba and tributary streams. The hydraulic tailing on the Yuba basin ranges in depth from 10 to 40 ft., and overlies the old river gravel in which the greater part of the gold recovered is found, though the tailing also carries a small amount of gold. The bedrock of the gravel deposit is of volcanic ash, similar in character to that of the Oroville district. In some places gold was found below the bedrock when drilling prospecting holes, but usually the volcanic ash was found to rest on the true bedrock. The gold sometimes forms several pay-streaks in the lower gravel, and in dredging part of the soft bedrock, which is similar to false bedrock found in other districts, is usually dug. The gravel in the Yuba basin averages in value from 10 to 30c. per cubic yard. Both of the companies operating in the Yuba basin coöperate with the United States Débris Commission in the construction of walls to control the flow of the Yuba river near Daguerre point. Two parallel walls, 30 ft. high for a length of about two miles, and forming a channel about three-quarters of a mile wide, have already been constructed from the dredge tailing.

On the property of the Marysville Dredging Co. a small town known as Marigold was established by the company, and comprises, besides the repair shops and company offices, a number of dwellings occupied by the employees and their families. The company put two California-type dredges, having buckets of 7½-cu. ft. capacity, in commission in 1906, but both of these boats have since been shut down. A third dredge was constructed in 1909, and put in commission in August of that year. The company now has two dredges operating. The following description of the new dredge, installed this year, is furnished by R. E. Cranston.

Dredge No. 4.

Lumber for dredge No. 4 began coming in about the middle of September 1910, and work on hull construction was begun soon after. The dredge was put in commission April 1, 1911. The lumber used was Douglas fir furnished by the Eastern & Western Lumber Co. of Portland, Oregon. The dredge was designed by the engineers of the Marysville Dredging Co. The General Electric Co. furnished the electrical equipment, the Abner Doble Co. the pumps, the Robins Conveying Belt Co. the conveyor, the Boston Woven Hose & Rubber Co. the belts, and the Union Iron Works Co. of San Francisco built the main dredging machinery from the dredging company's plans and specifications. Taylor Iron & Steel Co.'s steel was used for the bucket line, Bethlehem steel for the larger and Columbia steel for the smaller castings, and Bethlehem forgings were used for the shafting. The construction of the hull and installation of the machinery was under the direction of the company's engineers.

The hull is 115 ft. long, 58 ft. wide, and 8½ ft. deep over all. Aft of the well is a 4½-ft. overhang on each side. The side planking is 6 by 8 in., the bottom 4 by 14 in. laid athwartships, and the deck planking is 4 by 6 in., laid fore and aft. The bulkheads are solid and built up of 6 by 12-in. timbers. The floor-beams are 8 by 12 in., the thwartship timbers 10 by 14 in., the clamps 10 by 14 in., and the deck-beams 8 by 10 in. All seams are calked with oakum and then filled with pitch. The inside of the hull and all timber joints were treated with hot tar. The outside is painted with mineral paint.

The four main timbers of the bow gantry are 16 by 20 in., the cross-braces 14 by 14 in., and height of the cap above deck is 37 ft. The cap is built up of two 24-in. I-beams, 100 lb. per foot. The total weight of the cap is 12,700 lb. The two upright timbers of the stern gantry are 20 by 20 in., the middle timber 14 by 20 in., the cross-timbers 14 by 18 in., and the height above deck 57 ft. The cap is a box girder built up of 6 by 6 by ½-in. angles, and ⅜-in. plates, and weighs 6430 lb. The upper chord of the main truss is 16 by 18 in., the posts and braces 16 by 16 in. Under the bucket-drive the posts are 16 by 20 in. and are capped with a heavy steel casting which carries the driving machinery. The truss rods vary from 2 to 3 in. The housing joists are 3 by 12 in., the studs 6 by 6 in., the side covering 1 by 4 in., tongued and grooved, the deck 1½ by 6 in., tongued and grooved. The first upper deck is 17 ft. above the main deck, and the second upper deck is 30 ft. above the main deck. There is a 15-ton traveling crane supported by 12 by 12-in. posts and 8 by 8-in. braces, with 12 by 12-in. caps. This crane will hoist 30 ft. above water-line and covers all the machinery of the bucket-drive.

The digging ladder is of the lattice type, is 115 ft. long, 4 ft. 7½ in. wide, and has a maximum depth of 8 ft. Its total weight is 94,400 lb., and is built up of four sections. The girder is built up of 5 by 5 by ¾-in. angles, ½ by 28-in. side plates, ½-in. bulkhead plates, 5 by 5 by ½-in. side-brace angles, 5 by 5 by ⅜-in. bottom-brace angles, 5 by 3 by ⅜-in. top-brace angles, ¼-in. apron-plate covered with ¼-in. removable liner-plates, and ½ by 8-in. chafing-plates; ⅞ and ¾-in. rivets are used. The stack ladder is also of the lattice type, is 140 ft. long, 4 ft. 4 in. wide, and 7 ft. deep. The total weight is 24,000 lb. and is built up in four sections. The girder is built up of 4 by 4 by 7/16-in. angles on top, 4 by 4 by ⅜ in. on bottom, 2½ by 2½ by ⅜-in. side-brace angles, the same for top and bottom braces, and a No. 14 steel cover-plate. The rivets are ¾-in. diameter. The stacker-belt is 283 ft. long, 32 in. wide, and 7-ply. It is driven by a 35-hp., 600-r.p.m., 440-volt motor, at a speed of 350 ft. per minute.

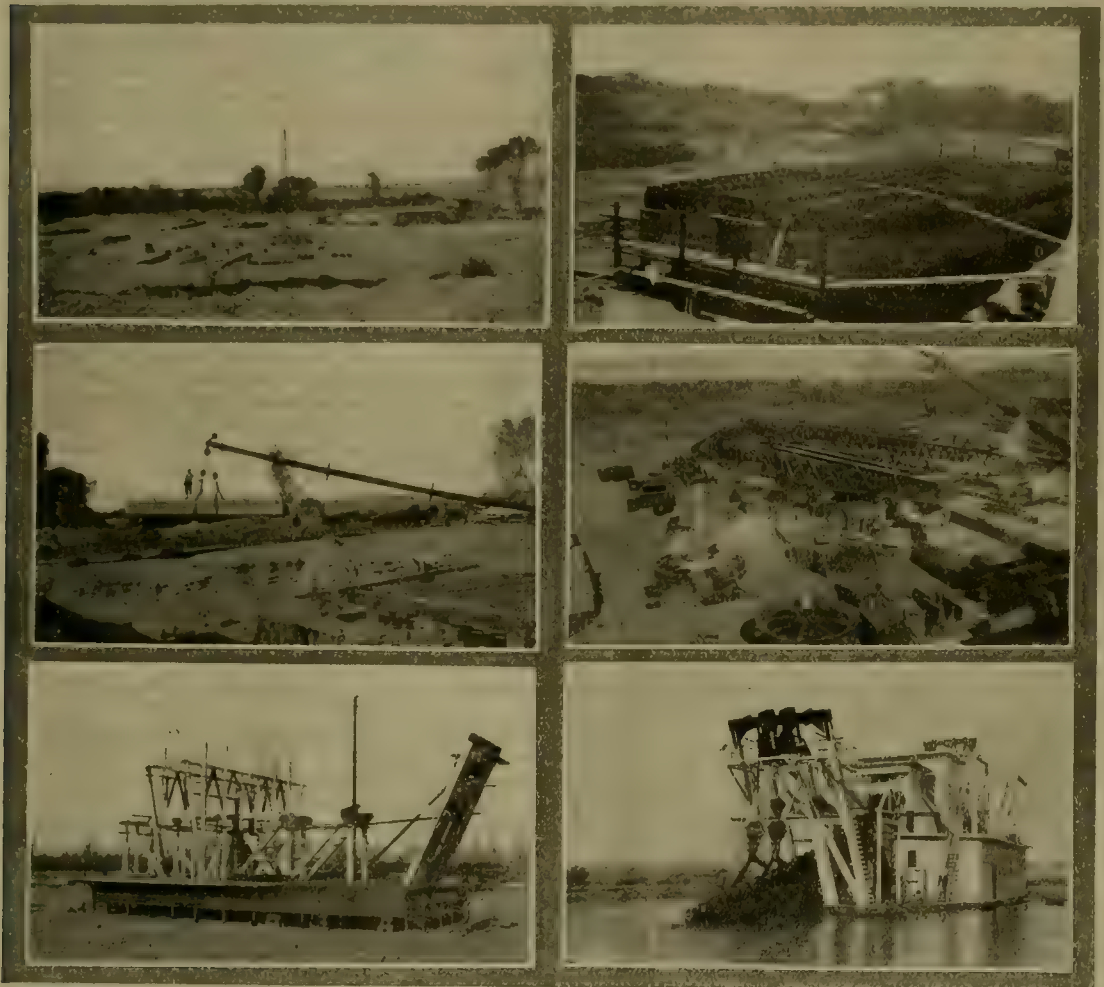
There are 84 buckets in the line, each made up of a cast steel base, pressed steel hood, manganese lip, bushings, and insert plate, and high-carbon, oil-tempered, forged steel pins. The base weighs 1527 lb., the hood 150 lb., the lip 280 lb., the insert plate 85 lb., the pin 160 lb., and the bushings 19 lb. The pitch of the buckets is 36 in.; they have two eyes in front and one hub in the back. The front eyes are each 4 in. wide, and the hub is 16¾ in. long. The pressed steel one-piece hoods are ⅜ in. thick, and the pins are 5¼ in. diameter and 25 in. long, of the L type.

The ladder rollers are made of cast chrome steel, 14 in. diameter, 2 ft. 9 in. long, with 5-in. diameter steel shafts. The weight of roller and shaft is 1140 lb. The upper tumbler, complete with wearing plates, weighs 15,500 lb. It is six-sided, each face being fitted with a removable wearing plate, cast of nickel steel. It is fitted with a 17-in. diameter, hollow, forged, nickel steel, oil-tempered, and annealed shaft, held in place by four keys, two at each side, 90° apart. The lower tumbler is cast in two halves and weighs 8320 lb. It is six-sided, has wearing-plates, and is fitted with a 12-in. hollow, forged nickel steel, oil-tempered, and annealed shaft.

The bucket line is driven through the upper tumbler by means of two gears at each end of the shaft, these gears being 12 ft. in diameter, 10-in. face, 2¾-in. pitch, and each weighing 10,200 lb. The intermediate pinions are 20 in. pitch diameter, and are fitted to a 9 in. shaft. The intermediate gears are 63 in. pitch diameter, 2½ in. pitch, and 8½ in. face. The pulley shaft pinions are 12 in. pitch diameter, and fitted to a 6 in. shaft, to which is also keyed the main drive pulley, 8 ft. in diameter and 25½ in. face. The digging motor is 200 hp., 440 volts, 600 r.p.m., variable speed type. At maximum speed it will drive the bucket line at the rate of about 22 buckets per minute. Besides driving the bucket line this motor also operates the ladder hoist, through a Moore & White clutch. The total weight of the ladder hoist is 39,000 lb. The base is built up of four 30 in., 120 lb. per foot, I-beams. The pulley shaft, which also drives the bucket line is 5⅞ in. diameter, and runs at a maximum speed of 215 r.p.m. The drum shaft is 9½ in. diameter, and the diameter of the drums is 48 inches.

The main winch weighs 23,275 lb., and is driven by a 25-hp., 600-r.p.m., 440-volt, variable-speed motor. There are seven drums, each operated by a direct-acting clutch. An electro-magnetic clutch is provided on the pulley-shaft to take up shocks. Gearing is provided for two speeds, the high speed driving the drums at 9 r.p.m., and the slow speed at 3 r.p.m. Two steel spuds are used; the total weight of each being 39,000 lb. The spuds are 61 ft. long, 3 ft. deep, and 2 ft. wide. The revolving screen is 36 ft. long and 6 ft. in diameter. The plates are ½-in. thick, and are perforated with ⅜-in. holes. It is on a grade of 2 in. to the foot, makes 7 revolutions per minute, and is driven by a 50-hp., 600-r.p.m., 440-volt motor.

The gold-saving tables are built of ⅛-in. steel, have an area of 2100 sq. ft. and a grade of from 1½ to 1⅝ in. per foot. Water is furnished by three centrifugal pumps. The high-pressure pump is direct connected to a 100 hp., 900 r.p.m., 440 volt motor. It has a capacity of 3200 gal. per min. under a head of 68 ft. The discharge pipe of this pump is 10 in. and the suction 12 in. The low pressure pump is direct connected to a 35 hp., 600 r.p.m., 440 volt motor. It has a capacity of 3900 gal. per min. under a 25 ft. head. The discharge pump is 12 in. diameter and the suction 12 in. The fire pump is direct driven with a 10 hp., 1800 r.p.m., 440 volt motor. The discharge is 2 in. and the suction 2½ in. The ladder-hoist lines are 1⅛ in. 6/19 plow-steel hoisting rope. The stacker and spud hoist lines are ¾-in. The swinging and head lines are 1 in., and the guy-wires vary according to the requirements. The ladder-line sheaves are 48 in. diameter, the spud, stacker, and swinging-line sheaves are 21 in. diameter. The buckets hold 8.6 cu. ft. of water, and the average digging capacity has been about 150,000 cu. yd. per month.



PHOTOGRAPHS SHOWING VARIOUS STAGES IN THE CONSTRUCTION OF MARYSVILLE DREDGE No. 4.

All of the coal-bearing rocks of the Appalachian field are of Carboniferous age. The Carboniferous in turn is subdivided into Pennsylvanian or Upper Carboniferous and Mississippian or Lower Carboniferous. The upper beds of the Lower Carboniferous are slightly coal-bearing in Virginia, and to a less extent in Tennessee. The main coal-bearing rocks of the Appalachian field are all of the Pennsylvanian age. Again, the Pennsylvanian may be divided into Pottsville or lower Pennsylvanian and post-Pottsville or upper Pennsylvanian.

Conservation of Investments in Gold Mines

By Morton Webber

The advance in the art of gold mining due to the practical application of modern engineering principles has been as great as in other industries, and yet there is none so discredited by the general public. That such is the case is strange, if viewed from a broad standpoint, and it is hoped that the dissecting of various causal conditions which are, with one radical exception, created and external, will enable the prudent investor to understand the fundamental necessities for successful investment. In respect to the foregoing anomaly, can those interested in the building of ships, various electrical devices, or the production of textiles, estimate with confidence the selling value of their product, even one year ahead? They can neither safely forecast the marketing of their product, nor make reliable estimate of the cost of their raw material. In point of fact, the gold industry is immune from nearly all the mutations of trade, especially competition and overproduction. In respect to mining, the majority of laymen prefer an investment in coal or copper to gold mines, although, in the last few years, phenomenal fluctuations in both have occurred. Gold being the standard, its price is $20.67 per ounce, and will remain so until another standard is chosen.

The administration of a standard mine makes paramount the existence of ore reserves that are fully blocked out and the net profit computed on the basis of past costs. The tonnage of the reserves varies from three to five years ahead of the crushing requirements of the mill, variations of reserves being largely subservient to the lateral and vertical opening up of profitable orebodies, against consumption. If a hypothetical example be taken of a mine that exhibits an ore reserve fully blocked out to the extent of four years supply, and equal in value to the past average assay, it will be seen that the profits of the future are assured without reasonable chance of loss, to the extent of that duration. The profits afterward that may be obtained from subsequent reserves may be considered; but the important point to the investor is that his capital, in event of the mine paying 20% in dividends per annum, is definitely assured, less interest, to the extent of 80%. The balance of 20% is represented by orebodies below the lowest level, and lateral possibilities; which are not computable assets. If the bottom of the mine is sound and the breast of the drifts are in good ore, the small proportion of capital so allocated may reasonably be expected to have a good return.

Ignoring the created and external disadvantages, is there any other industry that can show such an assured future, and, moreover, for such a long duration? Is there any who can say: "My capital is secured to 80%, my profits are guaranteed for four years, the selling value of the product will always be the same, and, moreover, if it is possible to reduce the cost of production, that reduction will be tantamount to extra profit, and I will not be subjected to underselling by others who likewise are able to reduce production costs?"

The foregoing, to use a stock expression, has shown the 'bull' side, as I have ignored the disadvantages which, as stated, are, with the exception of one radical demerit, purely created and external. The 'bear' side will now be treated, which, in the present condition of mining finance generally outweighs, to the layman at least, the advantages before presented.

The most important features are the methods of capitalization, and want of adequate amortization of capital, which are interdependent. Because of its destructive nature, there is no industry where the necessity for legitimate low basis of capitalization is more pronounced, and there exists no industry where the necessity is, in general, more ignored. As mining is destructive, no mine is a financial success until it has refunded its capital entire, plus interest at a rate commensurate with the risk, and when this is accomplished, the property should exhibit sound indications of future life. As this is a fundamental condition of the industry the uphill fight is obvious that even the finest mines must face when saddled with excessive capitalization; and what is habitual, being burdened with shares they are expected to pay dividends upon, when, in point of fact, they do not represent money expended in development or equipment.

For example: A mine is capitalized at $1,000,000; the company possesses a really good property, well equipped and managed, and reported on by a mine valuer of reputation. The engineer (in too many cases) reported on the mine as a mine and not as to the profit in the orebodies, against the automatic destruction of $1,000,000. The question of profits now comes up, and the mine goes on, year after year, making a clear gain of $100,000, sufficient to yield 10% over and above cash reserves. It is evident that if the regular dividing of such material profits continues for several years the company would become accredited in the mind of the public. If this regularity continued until the fifth distribution of $100,000, and at that time there were four years' ore reserve in sight, it is probable that the stock would be quoted at least at par. Four years' profits assured is a long time in the mind of the public, although from a valuation standpoint duration is unimportant; it is percentage of market valuation that is basic, and 40% is in most instances too little. Sixty per cent is too much to pay for the future of most developed mines, if the investor would be guided by experience and not be misled by exceptions, as, for example, a South African banket, and a replacement deposit where strict ore-blocking is difficult.

If the ore-shoot pinches out vertically and laterally by development in the sixth year, which is the consumption for the tenth, the position summarizes: Nine years at 10% dividend will equal $900,000 plus the market valuation of the plant, which will vary from zero up, depending on efficiency and location. Any profit derived from the extremities of the mine, together with the marketing of plant, may well be reckoned as being absorbed by fruitless subsequent prospecting and winding-up charges; it is surprising the money that has been lost in this respect on the termination of a mine. To recapitulate: The company shows a loss of $100,000, despite a nine years' period of apparent prosperity. The loss in reality is materially greater, for the accumulative interest problem must be considered, the position being only eight payments of $100,000 carrying cumulative interest from eight years down to one year as distributed, against cumulative interest on $1,000,000 for nine years *throughout*, which is from date of inception until the last dividend payment, when the calculation terminates. Taking cumulative interest at 4% in both cases, the total loss is increased to $363,036; the cumulative interest loss alone amounting to $263,036. If the company had been able to have actually refunded the total capital, just taking out of the ground as much as put in by capital, the loss through interest on $1,000,000 would be $279,636; cumulative interest on the capital for ten years being $480,240 and cumulative interest on the nine distributions of 10% amounting to $200,604. The difference in one year against the mine, to make plain, is owing to the fact that the first dividend is only paid to the shareholders at the termination of the first year. The question of cash in hand is ignored to promote facility in explanation, and is immaterial, because the conserving of finances would be automatically succeeded by dividend reduction. Very few investors appear to appreciate the magnitude of the cumulative interest problem.

If the above example be applied to a shipyard or manufacturing plant similarly capitalized, and distributing the same rate of profit, it is incontestable that the investment would be a genuine financial success and, being *constructive*, might go on indefinitely, depending on trade. But because, as a fundamental, the mining done by the company is *destructive*, a loss eventuates, owing to the capital destroyed, plus interest loss, in the removal and treatment of each ton of ore, which is greater than the net profit realized from the mining and treatment of that ton.

In dealing with capital amortization the latent disadvantage of the industry is seen, in that each unit of ore exhausted is responsible for an automatic destruction of capital. The heavier the capital and the less the total ore in a mine, the greater the destruction per unit, and conversely. An amortization rate is therefore the percentage of dividend that can be only regarded as refunded capital; and if so treated, provided that the mine has been legitimately capitalized, will, on the mine being worked out, be found to have returned the original capital plus interest. A shareholder may invest in a mine that may yield 20% for 20 years. If he spend dividends as received, on the termination of the mine he will have neither capital nor dividends. If an amortization of 25% of the dividend per year were imposed, on the twentieth year his capital, plus cumulative interest, is refunded, and he has received in addition $3 for every $1 invested.

The systematic reinvestment of capital is therefore, as an alternative, strongly advocated to stockholders, but the extra advantages derived from amortization of capital by mining companies, on their own part, are far-reaching in the extreme, and would probably remove many of the gravest demerits of the destructive industry. Every investor knows the difficulty mining securities experience in picking up after being quoted 'ex dividend.' This is owing to the removal of values that are irredeemable, the mine being impoverished to that extent, with the concurrent destruction of a proportionate unit of capital. It is evident that if mining administrations deducted an amortization rate to reinvest in stable securities to be liquidated only on shutting down and compulsorily divisible by articles of association, the share certificates would carry with them repayment of capital plus cumulative interest; the capitalization automatically decreasing by the substitution of a simultaneous representation in securities as the orebodies are removed. An intending investor would therefore be enabled to invest at any time on a legitimate basis, as his certificates would carry the destroyed capital up to date of investment. In the present conditions an investor buying after a mine has refunded its capital, in the event of the shares being at par, is, generally speaking, doomed to disappointment; as in point of fact only a small minority of gold-mining companies return two capitals.

In the case of vein mines I would suggest a basis of ten years in which to mature the amortization of capital; and in the event of a mine being sufficiently productive, to refund the capital in a proportionately shorter time. On a ten-year basis a mine capable, after providing operating cash reserve, of paying 20%, only 10% would be paid away in dividend, and the remainder of 10% would be reinvested in securities as capital amortization. On the conclusion of the tenth year the company's stock would carry the original capital plus cumulative interest, which latter would go on increasing in proportion to the life of the mine, and the administration would then be at liberty to divide profits in their entirety, and no matter what underground privation took place, the stock would always be worth at least par up to the last day of life.

If the hypothetical mine were subjected to exactly double the capitalization, but similar in other respects, no dividend could be paid for ten years, as the rate would absorb the 10%. In the latter case the conserving of dividends, which would be otherwise paid and possibly spent by the certificate holder, is in reality a blessing in disguise. A much wider advantage would really accrue, as it would teach the promoter to keep capitalization down to a basis of actual requirements and his eyes a little less on the ability of the market to absorb stock.

It may be suggested, as a compromise, that when a mine's capital has been amortized, the securities could be liquidated and the proceeds divided. The shareholders would then have control of their proportion of amortized funds, which would be free for reinvestment in other securities carrying a higher rate of interest. Superficially, the former suggestion seems preferable, especially as it is the case that on the liquidation of securities stockholders would virtually have the future of their mine for nothing, and the option of holding for future dividends or realizing at the market valuation. Numerically, the advantages are greater, but they are overshadowed by the fact that the amortization backing would be withdrawn at the most indispensable time, as a mine is always drawing nearer its exhaustion, and a subsequent holder would be then, as now, faced with the problem of diminishing capital on the one hand against incoming dividends on the other. With the exception of a South African banket, how many stockholders can with confidence say that, at the market valuation of their stock, it is financially better to let capital go and to hold for dividends? There must be few, if their deductions are based on the indefinite stereotyped information supplied by some directorates.

The subject of conservation and redemption of capital is inimical to the vested interests of a large element in the mining business, which depends on its speculative aspect. Endeavor has been made to bring the finance of gold mining down to the more temperate conditions found in the less speculative industries. To do this, the investor can not too well familiarize himself with the basic fundamental that mining is a destructive industry automatically destroying capital in the production of profits. To meet this, I advocate amortization by mining companies, and that by the articles of association, when the mine is worked out, the proceeds be divisible to certificate-holders. Until mining finance is perfected to this point, the investor should amortize his own capital for his own protection. This is only a compromise to meet conditions as they are, because while it will assist the individual, it will not benefit the industry from the broad standpoint attained by public company amortization.

Detecting Adulteration of Oils

Alex. E. Outerbridge, Jr., in the *Iron Age,* discusses the methods for detecting the presence of adulterants in oils. De-bloomed mineral oils are free from bloom (fluorescence) in bright sunlight, or ordinary diffused daylight, or the light from an ordinary electric arc, but they all become highly fluorescent when exposed to the ordinary enclosed arc; which happens to give out rays of the exact wave length needed to enormously increase the fluorescence. The light should be so inclosed that the arc burns in a partial vacuum, or at least the air is rarefied, and after burning a minute gives a faint rosy light in addition to the powerful white light. If a vessel containing any mineral oil, crude or refined, or any resin oil, be placed in the path of these rays, the most intense fluorescence appears, even in daylight; greenish in the case of mineral oil and blue in the case of resin oil; thin films glowing in the same manner. So strong is the fluorescence that 1 c.c. of crude mineral oil has been detected in 999 c.c. of non-fluorescent oil. "It is stated in some text-books that 'oleic acid' which is found in lard oil is fluorescent. On examination I find that pure, white, strained lard oil is entirely free from fluorescence under the 'ultra-violet ray, but all of the samples of so-called No. 1 or No. 2 lard oil (sold for use in machine shops) examined possess some fluorescence, and this may prove to be a novel means of rapidly determining the proportion of oleic acid in lard oil, though I only suggest it tentatively." To carry out this test systematically, it is desirable to put the standards in narrow tubular oil-test bottles, holding about 50 c.c. each; corked, labeled, and placed side by side in small wooden racks on a shelf in proximity to an enclosed arc light; beginning with a pure oil on the left hand side, then bottles with 0.1% mineral oil, 1, 2, and up to 10%. The standard with linseed oil serves to examine cottonseed, corn, China-wood, China-bean oils, or any other non-fluorescent vegetable oil. The special standard of lard oil is necessary to test adulterated lard oils.

Exports of merchandise in September last amounted in value to $195,771,000, against $168,874,000 a year ago. Imports were $125,158,000, against $117,265,000 a year ago, according to the Bureau of Statistics.

Geological Factors in Oil Production

By Dorsey Hager

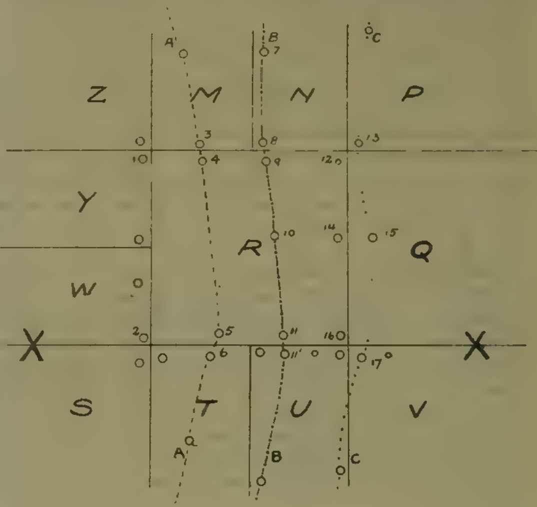
Much has been written concerning the value and use of geology to the petroleum industry. The larger number of articles discuss the general structural features of oilfields and the locating and prospecting of oil lands in accordance with structural features (anticlines, monoclines, terraces, and domes). Surprisingly little of the literature deals with the technology of petroleum mining, or with the application of geology to special problems that arise in drilling for oil, or to the problems that are met in planning a campaign to economically obtain the greatest production of oil from a property in the shortest time. This article will deal with the problems that arise in planning a production campaign. Later I hope to present some of the special problems involved in drilling and in operating wells.

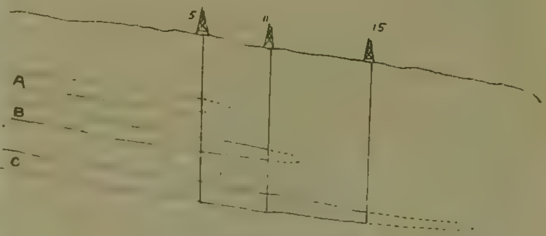
The aim of every operator is to extract the maximum of oil in the minimum of time and at a minimum cost. To accomplish this he must map out a definite production campaign. Successful operating depends upon the ability to clearly analyze and comprehend troubles two thousand feet or more underground. Such ability often saves many thousands of dollars that would otherwise be expended in futile endeavors to remedy some of the trouble that does not exist. Geological conditions two thousand feet underground may seem largely a matter of conjecture. However, an excellent idea of such conditions can be obtained by a careful study of: (1) any outcrops of the oil strata and the beds underlying and overlying them; (2) the drill-logs and borings from individual wells; (3) the cross-sections and the areal maps made from a compilation of a number of drill-logs.

From the first source of information some clue to the following may be obtained: (*a*) the hardness of the formations; (*b*) the thickness of the formations; (*c*) the dip and the strike of the oil-strata; (*d*) the size of the sand-grain of the oil-sands; (*e*) probable water sands; (*f*) evidences of faulting and minor folds that may affect the oil-strata. From the second source of information may be gained: (*a*) knowledge of the actual depths to the oil-strata; (*b*) the number of oil-strata; (*c*) the true thicknesses of the oil-strata; (*d*) the true thicknesses of the overlying beds; (*e*) the relative productivity of the oil-sands; (*f*) the character of the beds overlying the oil-strata as regards hardness, and whether they are shales or sandstones; (*g*) the relative position and number of water-sands; (*h*) the quality of the water, whether alkaline, saline, or sulphurous. The third source of information gives: (*a*) the areal limits of the several oil-sands; (*b*) the areal limits of water-sands; (*c*) the changes of oil-sands to water-sands; (*d*) the changes of coarse sands to shales; (*e*) the true dips of the oil-sands; (*f*) the thickening and thinning of the oil-strata in accordance with overlap. All of the information given above is of great value to the oil-man, who is planning a production campaign. Indeed, the time will come when no operator will begin work on a large scale without taking these factors into consideration.

Three important problems confront the operator: (1) how best to obtain the largest quantity of petroleum from his own property; (2) how best to defend his property from drainage by neighboring properties; (3) how best to drain neighboring properties. At first glance problem 3 may seem to call for illegal proceedings. Petroleum mining, however, differs from other mining in that there is no legal liability for the operator who depletes a neighboring property, while in mineral mining no operator can obtain ore from neighboring property without being responsible for the mineral so taken. The reason for this difference lies, of course, in the nature of the substance mined. Petroleum is a fluid, while the minerals are solids. Petroleum, like water, seeks its level and also tends to flow through any outlet that offers easy passage. Such being the case, it is by no means a simple matter to determine the quantity of fluid that one property may drain from specified neighboring properties. While it is possible to tell approximately how much oil has been obtained from other properties, it is not possible to tell how much oil has been drained from a certain acreage, specifying the amounts taken from each neighboring property. Because of this uncertainty no legal action can be taken against an operator, even though his oil-wells may have completely exhausted neighboring territory.

Every operator desires some idea of the amount of oil he may reasonably expect from a property. Estimates of this kind are only approximate, but are useful guides to conservative men. The following factors are necessary in computing the quantity of oil that a property may reasonably produce: (1) the number of oil-strata; (2) the thickness of the various strata; (3) the porosity of the oil-bearing formation; (4) the areas covered by each stratum. The first two factors may readily be secured from the drill-logs. The third factor can only be secured by a study of the drill cuttings and the outcrops of the oil-sands. The fourth factor requires a careful study of cross-sections and contour maps made from a compilation of many drill-logs. Assume a property covering a section of land, 640 acres, in proved territory. Three productive sands are known. Drill-holes No. 1, 2, 3, 4, and 5 show three distinct oil-sands, A, B, and C, with thicknesses averaging, respectively, 30, 30, and 50 ft., but with a gradual thinning eastward. Drill-holes No. 6, 7, 8, 9, 10, and 11 show two sands, B and C, having average thicknesses of 30 and 40 ft., respectively. Drill-holes No. 12, 13, 14, 15, and 16 show but one oil-sand 30 ft. thick. It is clear that the three strata, A, B, and C, do not all underlie the full 640 acres under consideration.





CROSS-SECTION ALONG X—X.

The average of each sand that underlies the property is a matter of approximation. Drill holes No. 4 and 5 show the three sands, A, B, and C, while No. 9, 10, and 11 show B and C. Evidently the top sand A has given out somewhere between No. 4 and 9 and No. 5 and 11. This being the case, it is safe to assume the limits of the A sand at No. 4 and 5. This gives 200 acres covered by A and possessing an average thickness of 30 ft. Sand B, as shown by the drill records, extends to No. 9, 10, and 11, which are taken as its limits. The acreage covered by B is 400 acres, with an average thickness of 25 ft. C covers the entire 640 acres, with an average of 40 ft. All told, there are 200 acres 30 ft. thick, 400 acres 25 ft. thick, and 640 acres 40 ft. thick; a total of 200 by 30, or 6000 acre-feet, plus 400 by 25, or 10,000 acre-feet, plus 640 by 40, or 25,600 acre-feet; a total of 41,600 acre-feet.

This total is a fair estimate of the total amount of oil-sand underlying the section. The porosity of oil formations differs so materially that no constant should be assumed except as an approximation. Sands show from 5 to 20% porosity, and some dolomitic limestones as high as 33%. Generally, however, 10% is accepted as the basis for estimates. The U. S. Geological Survey accepts 10% in most of its computations. One gallon per cubic foot is often taken, or nearly 1000 barrels per acre-foot. For the purpose of illustration, the latter estimate will be assumed. Thus 41,600 multiplied by 1000 equals 41,600,000 bbl. of oil underlying the property. It is safe to assume that only 50% of this oil is recoverable.

Experiments made by the U. S. Geological Survey (see Bull. 475, pp. 12 to 16) show that with Pennsylvanian and Illinois petroleum of 0.810 (43°B.) and 0.8375 (37°B.) specific gravities, respectively, fuller's earth will absorb, on an average, 40% of oil that cannot be recovered. Experiments have not yet been made to ascertain the percentage of oil retained by the coarser-grained oil-sands. With heavier-gravity oil of increased viscosity it is safe to assume fully as large a loss as that given with fuller's earth.

Added to this loss by retention due to adhesion and friction is the incomplete drainage of the oil-sands by drilled wells. This last factor is most important. There comes a time when the oil accumulates in a well so slowly that there is little economy in pumping it. When this point is reached the oil property is abandoned as of too little value to pay for operating. It is economically exhausted, though not actually so. The above losses do not take into account possible flooding, cave-ins, or drainage by neighboring properties. When all these factors are considered, 50% seems too high an estimate. However, for general purposes this figure is acceptable. There are, then, 20,800,000 bbl. of oil that may be extracted from the property under consideration. Call this figure 20,000,000 bbl. for safety.

The next step is to find the number of wells that will be needed to obtain this oil. Here again assumptions are necessary. The acreage drained by one well is variously estimated at from one to six acres. Little definite information is available as to the acreage per well that gives the best results. Four to five acres is accepted as good practice, but whether or not this is the best figure cannot be said at present. Some operators space their wells 100 to 800 ft. apart, varying the distance inversely with the richness of the 'sands'. Taking five acres as the basis, 128 wells per section would be required. I suggest below a method of determining the proper number of wells to a certain acreage. This method is submitted only as a suggestion. Obtain data covering a large number of wells, and note their ages, the thicknesses of the sands, the fineness or coarseness of the sands, and the total production of each well. From these data construct tables that show the ages of the wells and the average productions for varying thicknesses of the 'sands'. As an indication of the use of such data, take the following illustration.

The property, 640 acres, shown in Fig. 1 is underlain by three sands. The table below shows the known and computed information needed before using the tables mentioned above, prepared from a study of a large number of wells.

I. Acres underlain by sands	II. Thickness of sands under each acreage	III. No. acre feet	IV. Computed quantity of oil available in bbl.
200	95	19,000	9,000,000
200	65	13,000	6,600,000
240	40	9,600	4,400,000
640		41,600	20,000,000

TABLE A.

From the above table columns I, II, and IV are of importance in reaching a conclusion as to the number of wells needed and are used in Table B.

I. Thickness in feet of sands	II. Production for thicknesses given in I.	III. Life in years for thicknesses in I.	IV. No. of acres	V. Computed number of barrels of oil available	VI. No. wells needed	VII. No. acres per well
95	180,000	9	200	9,000,000	50	4
65	120,000	7	200	6,600,000	55	3.6
40	80,000	5	240	4,400,000	55	4.4
			640	20,000,000	160	Av. 4

TABLE B.

Columns I, IV, and V are taken from Table A and correspond to columns I, II, and IV, respectively. Columns II and III are derived from data collected from a study of a large number of wells. Column VI is obtained by dividing the figures in column V by those in II. Column VII is obtained by dividing the figures in column IV by those in column VI. These results are purely assumptive, and should in no way be considered as of value, except for the purpose of illustration. I offer this method as a probable means of securing satisfactory data, not as a carefully worked out system of proved value.

The problem of securing the greatest quantity of petroleum from a property is intimately associated with the problems of securing: (a) the greatest quantity of petroleum from neighboring properties; and (b) protecting our own property from drainage. Many other minor problems, such as water troubles (sometimes a serious menace to a whole oilfield), cave-ins, collapsed casing, leaks due to filling of dry sands, and others, will be treated after considering the main problems of well-location. Consider the problems involved in securing oil from neighboring properties. Fig. 1 shows a number of properties surrounding *R*. There are *S*, *W*, *Y*, and *Z* above *R* on the dip. There are *M*, *N*, *T*, and *U* on each side of *R*, and there are *P*, *Q*, and *V* below *R* on the dip. The three sets of properties require different treatment for offense and defense. In a new field where the gas pressure is strong, the oil generally tends to migrate upward from points on the lower dip. However, in older fields, the tendency of the oil seems to be downward, under the effect of gravity. Friction, in some cases, especially where the dip is slight, will keep the oil from traveling downward.

The usual practice of offense consists of the following elements: (1) to sink wells before one's neighbors; (2) to drill holes of larger diameter than those of the neighboring companies; (3) to drain sands unknown to the neighbors; (4) to place the wells so as to be sure of draining as much territory as possible; (5) to speed the wells as fast as possible.

It is almost a self-evident fact that the first well in a field has an advantage over all other wells, other things being equal. If one company completes a well a month ahead of another, it is but natural that the first well will take the cream of the production. But more than this is likely to happen. The first well may form channels which will effectually drain a territory, and a neighboring well or wells will suffer in consequence (see Fig. 2). This was supposedly the reason for the barrenness of the wells contiguous to the Lake View gusher. In this case the theory seems correct, as recent reports indicate that wells nearby have greatly increased in production since the great gusher has ceased flowing.

Wells that have a casing diameter of 8 in. certainly have an advantage over wells that have diameters of 4 and 6 in.[1] The larger-sized casing will stand more rows of perforations, which means a greater surface exposed to the oil. Also, the interior of the casing will give a larger collecting basin for the oil. In this latter case the ratios of the larger-sized casing to the smaller will be $8^2:6^2:4^2$ or 64:36:16. Thus the 8-in. hole will give four times the collecting basin of the 4-in. hole and nearly twice the basin of the 6-in. hole. However, the relative exterior surface exposed to the oil-sands will not bear the same ratio. Perforations vary greatly in size, from ⅜ by ¾ in., ⅜ by 2 in., ½ by 1 in., to ½ by 3 in. and larger, depending upon the different companies. Generally these perforations are in longitudinal rows and evenly spaced, one every foot or six inches. A 4-in. casing is given three rows of perforations, a 6-in. casing four rows, while an 8-in. casing carries five to six rows of machine-made slots.[2] Whether a rolling knife or casing 'splitter' is used, there is little regularity of rows. If the size of the perforations is the same and the spacing equal, the ratios are 6 to 4 to 3. The 8-in. casing exposes twice the surface of the 4-in. and 1½ times the surface of the 6-in. The advantage is certainly with the larger-sized casing.

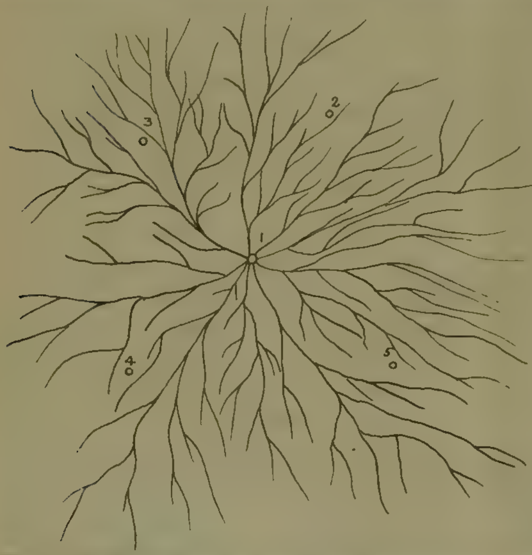


FIG. 2. SHOWING HOW A WELL MAY ESTABLISH DRAINAGE LINES AND DRAW OIL FROM SUBSEQUENT WELLS.

It may seem a rare occurrence for a company to tap oil-sands unknown to its neighbors. This, however, is not an unusual occurrence, especially where companies have failed to prospect for deeper sands. It is then discovered too late that more venturesome neighbors have tapped the lowest sands and gained a good production at the first concern's expense, having drained much of the property of the careless concern. Again, companies often wilfully hold back information regarding their prospect holes, and give misleading information as to lower sands. However, no company is under moral obligation to give information to competitors, unless prospect holes show water sands that may endanger the neighboring properties as well as their own. There are, however, cases that have been reported where concerns have deliberately flooded a field, or portions of it, to drive the oil from neighboring properties to their own, or where by destroying neighboring lands these companies have benefited by a loss of competition. Whether or not such charges are true, I do not pretend to assert. They may only be the result of perfervid imaginations.

The question of placing wells so as to drain the largest possible territory involves some interesting problems. One case in particular seems worthy of study. In one of the Oklahoma fields an independent operator held a very good oil property which he desired to develop. Upon investigation it was found that the only pipe-line in this field was owned by a Standard Oil subsidiary, which owned all the neighboring land, or rather held leases on it. The independent operator could not afford to build a pipe-line of his own, and the corporation held him up for transportation. Obviously, the only thing he could do was to keep his land. Unfortunately for him, the Standard leases were lower on the dip, and as this concern was developing its properties, the independent was forced to give up hope of getting any oil from his property. The Standard concern would not buy his land, so that in time the property was exhausted without the independent obtaining anything for his share. This is an extreme case of drainage. However, the same principle applies to nearly all oilfields where one company is favorably situated to drain oil from others. The principal elements considered in placing a well to best drain a neighboring property are: (a) the spacing of wells; (b) the degree of dip of the oil-sand.

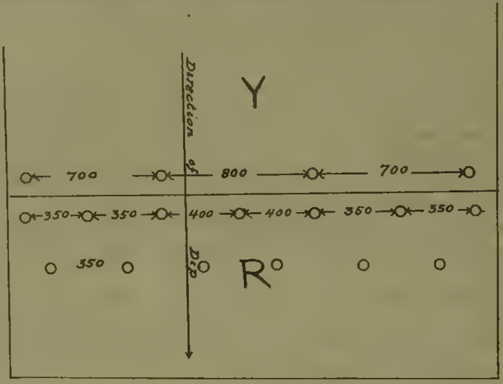

FIG. 3.

Where an opposing company has already sunk its wells, there are certain lines of procedure that may be successful. If its wells are far apart it will be of advantage to place wells at intermediate points as well as opposite the other wells. (See Fig. 3.) The wells on *Y* are spaced 700 and 800 ft. apart. Wells on *R* may then be spaced 350 and 400 ft. apart. This will force the *Y* operators to drill wells between the others. This being the case, the *R* operators have the advantage of being down the dip, and by placing back wells at points intermediate between the first row of wells (see Fig. 3), effectually cover all the line presented by *Y*, and, having more wells, should draw the oil more rapidly than the single line of wells. This condition is by no means a theoretical one. It exists in a number of places, but is often quite unnoticed.

Speeding the wells as fast as possible is one of the means of obtaining more oil than neighboring companies. But there is a decided limit to such speeding. There must first be oil enough to pay for pumping wells rapidly. In some places the oil seeps into the well basin slowly and is pumped off in a few hours. Rapid pumping is here needless and expensive. In other places there is plenty of oil, but rapid pumping produces unfavorable conditions, such as drawing large quantities of sand into the well, and consequent trouble with the well. Then, too, there is a limit to the speed that the pump rods (sucker rods) will stand without breaking, and to the effect of the speed upon the pumping jack or upon the derrick and the machinery. In some cases where the speed of the wells might readily be increased the effect upon the machinery might result in serious break-downs and accidents. A rational method of offense would combine all these elements.

---

[1] Sizes rated generally at 8¼, 6½, 6⅝, and 4½ in. diameter.

[2] Four, six, and eight-inch casings are listed as 8¼, 6⅝, and 4½ inches in most oilfields. Called by even inches for convenience.

The problem of defense is next in order. The elements to be considered are much the same as those of offense. If a neighboring property is being drilled, wells must be drilled to offset the neighboring wells. If a neighbor finishes his wells with casing of large diameter, he must be met with the same size or larger. If the neighbor penetrates sands not before known to exist, then the wells must be deepened to offset the wells of the neighbor.

Often, indeed in most cases, a property may embody the principles of offense against properties higher on the dip and defense against properties lower on the dip. Thus, in Fig. 1, the properties *S*, *W*, *Y*, and *Z* are on the defensive to *R*, and *R* is on the defensive to properties *P*, *Q*, and *V*. So in Fig. 4, *Y* is on the defensive to *R*. In this latter case, when wells are drilled on *R* intermediate between those of *Y*, the operators on *Y* would have met this attack by drilling wells to offset those on *R*. When the *R* wells are pumped rapidly the *Y* wells must be speeded to meet the increased drain. Indeed, the *Y* property is at a decided disadvantage as regards attacking *R*. Such being the case, all that can be done is to keep up as vigorous a defense as is possible under the conditions. Different systems of offense and defense have been worked out, by many companies. However, the problems presented in this paper embody the essential features of such systems.

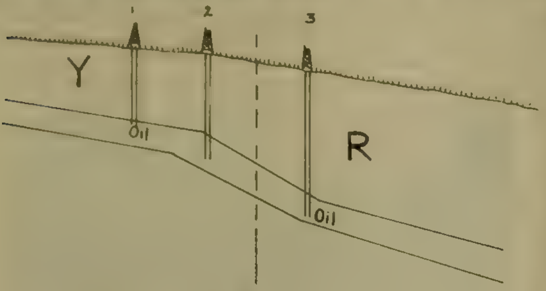

FIG. 4.

THE problems of smoke elimination have by no means all been solved. The most vexatious source of smoke in many cities is probably the railway locomotives. It yet remains for some genius to discover a method of burning soft coal in locomotive furnaces without smoke. But here more than anywhere else the care exercised by the fireman, or the lack of care, shows in the volume of smoke produced. Fifty per cent of the smoke made by a careless fireman can be obviated by the enlightenment of the fireman. When this fact is realized, our cities can at least demand of railways that they make their minimum of smoke. Furthermore, the cities would be well within their rights were they to demand that switching engines be supplied with coke or other smokeless fuel. This would certainly help to mitigate the smoke nuisance. With the smoke from factories and the railroads reduced to a minimum, the irreducible remainder, and the apparently incurable smoke from kitchen ranges and open fireplaces, would make a total so far below what most of our cities now endure that city life would be made notably cleaner and sweeter, and, in addition, living conditions would be much more healthful, especially in cities where lignite is burned.

The Golden Cycle Dry Concentrator

By T. C. LINDERFELT and J. K. STEWART

The dry concentrator of the Golden Cycle company, at the mine at Goldfield, has a daily capacity of 75 tons, and was constructed to handle low grade ore from the mine. It presents many novel features in both process and operation. The ore, containing tellurides of gold, is crushed and screened in order to obtain a large percentage of the valuable mineral in the screenings. Owing to the brittleness of the tellurides, crushing tends to separate them from the worthless rock, and they are found with the fine mesh products.

The foundations of both building and machinery are constructed entirely of reinforced concrete, while the retaining walls are of masonry, waste rock from the dump being used for construction material. The building throughout is roomy, and well lighted by windows and electric lights. The superstructure and framework are of wood, the latter being of 8 by 8 in. and 8 by 10 in. timbers, spliced with lap-joints and secured with ¾-in. bolts. The flooring is of 2-in. planking and the framework is housed with corrugated iron.

The ore is trammed in 2-ton electric dump-cars, taking power from a third rail, to a storage hopper with a capacity of about 40 tons, which feeds the crusher. From here the operation is continuous until the ore is automatically loaded into railroad cars. The power is furnished by the Pueblo & Suburban Traction & Lighting Co. The current is transformed from a main power-line carrying 12,000 volts, to 440 volts for mill power. The motors are all Westinghouse induction A. C. motors. The main shaft is connected to an 85-hp. motor driving all the machinery in the mill and also the first relay of the tailing-conveyor. In addition to this, there is one 10-hp. motor driving the second relay of the tailing-conveyor, and one 5-hp. motor driving the third relay of the tailing-conveyor.

The ore passes over grizzlies to a 13 by 24 Blake crusher, which cuts it to about 2-in. product. From the crusher and grizzlies it is fed directly to a bucket-elevator, 20 ft. between centres, thence to three 3 by 8-ft. revolving screens of 1¾-in. mesh. The oversize goes to 16 by 30-in. parallel rolls. The undersize from the screens and the entire product from the rolls are fed to a 3 by 8-ft. revolving screen of 6 mesh. The oversize goes to a relay tailing-conveyor and is carried to the dump. The undersize, or concentrate, is carried by an 18-in. belt-conveyor, 300 ft. between centres, to a hopper of 25 tons capacity, whence it is loaded by means of a bucket-elevator and an 8-in. metal tube.

The tailing-conveyor is in three relays. The first is driven by the mill power and is 75 ft. between centres; the second is driven by a 10-hp. motor and is 150 ft. between centres; the third, driven by a 5-hp. motor and 75 ft. between centres, drops the waste on the dump. These three conveyors are made of 18-in. six-ply belting. The most novel feature of this plant is the system of 'tell-tales', devised by B. A. Searle, to indicate to the operator whether or not the relays of the tailing-conveyor are in operation. Idler shaftings at the end of both the second and third relays of the conveyor are extended into the respective motor houses. A 6-in. wooden pulley, in which is imbedded a ¾ by 5-in. metal plate, is keyed to each shaft. A pair of contact brushes are fastened to a framework in such a way that the circuit is opened and closed at each revolution of the pulley. Each of these sets of brushes is connected to separate lights in order that the operator may know which relay of the conveyor has stopped.

FEW mineral products have so wide a variety of uses as lime. Nearly half the lime manufactured in the United States is used as a structural material, and the remainder, amounting to about 1,750,000 tons, valued at about $5,500,000, is used for chemical purposes.

Ore Deposits Near Lake City, Colorado

By J. D. Irving and Howland Bancroft

*The principal product of the Lake City region has been silver, but lead, gold, and copper have to some extent contributed to the value of the output. Zinc has had practically no part in the production and has been one of the most objectionable components. If divided according to gold and silver content, the veins of the region might be classed as silver-bearing veins and gold-bearing veins. The tetrahedrite-rhodochrosite group and the quartz-sphalerite-galena group would fall together in the silver-bearing class, and the telluride group in the gold-bearing class. The details of ore content can be ascertained only from oral report for many of the mines, because many workings have been abandoned and records could not be secured. Other workings now ship low-grade ores, whereas those mined in early days were of very much higher grade.

In the silver-bearing group the present ores do not average much over $6 to $10 per ton and yield a concentrate worth about $40 per ton. This includes both the high-grade masses of tetrahedrite scattered through the ore and the lower-grade ores that are also a notable feature. In the upper levels of many mines the ore has ranged from $10 per ton up to $3000 per ton and even more. Eighty-five shipments of ore of about 25 tons each from the upper levels of the Vermont mine averaged 84.53 oz. silver and 27.96% lead, or approximately $44.80 silver and $12.06 lead, a total gross value of $56.86 per ton; 63 tons mined in 1894 yielded $79 per ton; and two shipments in 1895 and 1896 yielded $22.78 and $22.67 per ton, respectively.

The average of the ore mined in the Hidden Treasure mine in 1898-9 was about $7 to $9 per ton, yielding $41.67 per ton of concentrate. The Black Crook in 1884 produced 1227 tons of ore valued at $124,447, or about $101.39 per ton. All of these rich ores have now been exhausted and the ore must be milled. Probably very little of the ore runs over $5 to $6 per ton. Of the telluride or gold-bearing veins the Golden Fleece alone has thus far been a producer. Much of the ore it yielded during its early exploitation was of unusually high grade. The assay values in the ores vary so widely that it is not possible to lay down any rule which will not have many exceptions.

The lodes of Lake City are fissure veins formed partly through the replacement of shattered and sheeted zones in the country rock and mainly through the filling of open spaces. They average between 500 and 1000 ft. in length, have a similar vertical range, and an average width of 10 in. to 5 ft. They show a wide range of strike and dip at steep angles. They consist of three closely related mineralogic types. The first contains pyrite, galena, sphalerite, and chalcopyrite with subordinate tetrahedrite, in a quartz gangue with some barite and rhodochrosite, and yield silver and lead with subordinate copper and little gold. The second contains galena, sphalerite, and tetrahedrite with subordinate chalcopyrite and pyrite, in a gangue of quartz, barite, and rhodochrosite, and yield chiefly silver and lead. The third contains petzite, tetrahedrite, and minor quantities of other sulphides, in a gangue of fine-grained quartz carrying some hinsdalite in places; this type yields silver and gold in proportion by value of 1:1, and is characterized by high assay values in both gold and silver.

The first two groups constitute the bulk of the Lake City lodes, as there is but one productive telluride vein. Their ores are low grade where unaffected by surficial alteration, the major portion of the Lake City production coming from ores enriched by secondary sulphide enrichment that has produced chiefly pyrargyrite as a secondary mineral. Oxidized ores are widely distributed. Lodes are, for the most part, separated by considerable areas within which no veins have yet been found, the Capitol City group being the only closely spaced series of veins exploited.

The Lake City lodes comprise the northeastern portion of the mineralized area which includes Rico, Telluride, Silverton, and Ouray. The lodes show great similarity to those of these areas, but were probably formed under a slightly less cover of overlying rocks.

The lodes are later than all of the rocks exposed in the region except the rhyolites and basalts of post-Potosi age, and are hence of late Miocene or early Pliocene age. They are believed to have been derived from the vapors emitted from a magma of monzonite whose apophyses as intrusions are scattered through this region in considerable numbers.

The Lake City district possibly contains unworked and undiscovered veins that are similar in mineralogical character to those already developed, and it is on these, combined with the careful mining and milling of the ore from the veins already found, that the future of the district depends. A quantity of low-grade ore is now developed, associated with which is an enormous amount of zincblende. This ore may perhaps be treated with profit if the proper kind of concentrating works are erected, and the zinc may also be sold if mechanical means can be successfully used in its separation from the commonly associated minerals.

As the geology of the region has so little apparent connection with the deposition of the ores, it is impossible to lay down any rule as to the best places to look for new bodies of mineral. The richest mines are in the andesite of the Picayune volcanic group, but veins found elsewhere in the district have the same general mineralogic content, so that no inference can be drawn from the occurrence in this particular andesite.

The fact that some of the veins can be traced on the surface for considerable distances would seem to point to the general conclusion that the extension of some of the already profitably worked veins may be found by a careful study of the topography and the relation of the veins to it, taking into consideration their dip and strike. On the other hand, as it is rather evident that the district contains mainly only the roots of veins, it would probably be more profitable to look for new discoveries rather than the extension of those already worked, as doubtless the major part of these have been eroded away, leaving only their lower parts.

An interesting feature is the date of the location of the properties which have proved to be successful producers. Without exception the veins which were profitable were located in the early days of the mining activity. A great many prospects have been abandoned which show surface croppings just as promising as those of some of the profitable properties. Much of the loss that has been sustained in mining in this district has arisen from unjustifiably excessive initial expense. There have been some startling examples of reckless expenditure in the district, which tend to weaken the confidence of the mining public and to destroy any chance of obtaining funds for judicious exploitation.

Until recently a majority of large mines used coal for the generation of power. Lately a few dams have been erected and water-power utilized for the generation of electricity for the Hidden Treasure, Moro, and Lellie mines. The first two take water from Henson and the last from Nellie creek.

The steep gradient in most of the streams makes it easy to obtain the head necessary for hydro-electric installations in a region of limited water-supply. An objection, however, to this means of generating power is the low temperature which prevails during the winter months, at which time the streams throughout the mining district are frozen over. A means of obviating this difficulty is to build a dam at such a place that quite a deep body of water may be obtained, so that when the surface freezes there will be enough water below the crust of ice to furnish the requisite flow. The Hidden Treasure dam is said to be 100 ft. in height. The natural conditions of the banks of the stream are admirable for such a dam, and a great supply of water can be maintained. The officers of the Moro mine state that sufficient water is available to operate the mine during the entire winter, although they think it is doubtful whether they can generate enough power to operate both mine and mill during the months from December to May. In all probability it would not be possible to obtain water during

---

*Abstract from Bulletin 478, U. S. Geological Survey.

the winter months from any of the tributaries of Henson creek, they being frozen solid during the cold season.

The large mines using coal for the generation of power have been the Ute, Ulay, Golden Fleece, Black Crook, and until 1907 the Moro. They have obtained their fuel from Crested Butte, Colorado, when possible, and from Somerset, Colorado, when the Crested Butte coal was not to be had. Run-of mine coal sold at the time of writing (January 1909) at $2.50 to $3 per ton on the cars at the mine, and lump coal at $4.50 per ton in carload lots on the cars at Lake City. Run-of mine coal is said by some to be very satisfactory, but the lump coal is said to be about the most satisfactory in Colorado for steaming purposes.

Gasoline has been used at the Pelican property, but the foundation failed to withstand the vibrations of the engine and further use of the machine was temporarily abandoned. The company intends, however, to place the engine on a firm foundation and resume its use. Gasoline costs 16c. per gallon in barrel lots on the cars at Pueblo, Colorado, and that used by the Chicago Tunnel Site Co. is reported to have averaged 58° to 65° hydrometer test, each shipment, however, showing considerable variation. The Pelican at one time contracted with the Lake City power-plant to deliver electricity at the mine. After having erected the line, however, it was found that the company was unable to furnish enough power, and the scheme was abandoned.

The labor conditions in the Lake City district have been very uniform, and the differences between operators and laborers have been slight. When there has been great activity in the region it is understood that labor has been easy to procure. The wages paid are about the same as elsewhere in the San Juan region ranging from $3 to $5 per day according to the class of work.

GOLDEN FLEECE MILL.

The early work on most of the veins was carried on through drifts driven on the veins. The adits run at first were short and easily operated. This was very advantageous during the early stages of exploitation, when the deposits were easily accessible. As depth was gained, however, long cross-cuts became necessary for working, and these have almost invariably proved disappointing. The Vermont adit, T. C. M. adit, Lucky strike adit, Hidden Treasure adit, and many others, have been started, but so far none of them has had satisfactory results. Most of them have not gone as far as they had intended to go at the outset, as the character of the vein in depth did not seem to justify so great outlay. No deep vertical shafts are used in the mines, although several properties have developed the veins by inclined shafts following the general dip of the vein. The ore is transported from the mines by burros, wagons, or wire-rope tramways. The last named are used on the Hidden Treasure, Lellie, and Moro properties to connect the mines with the mills situated several hundred feet below the mine openings and from $\frac{1}{4}$ to $\frac{3}{4}$ mi. distant.

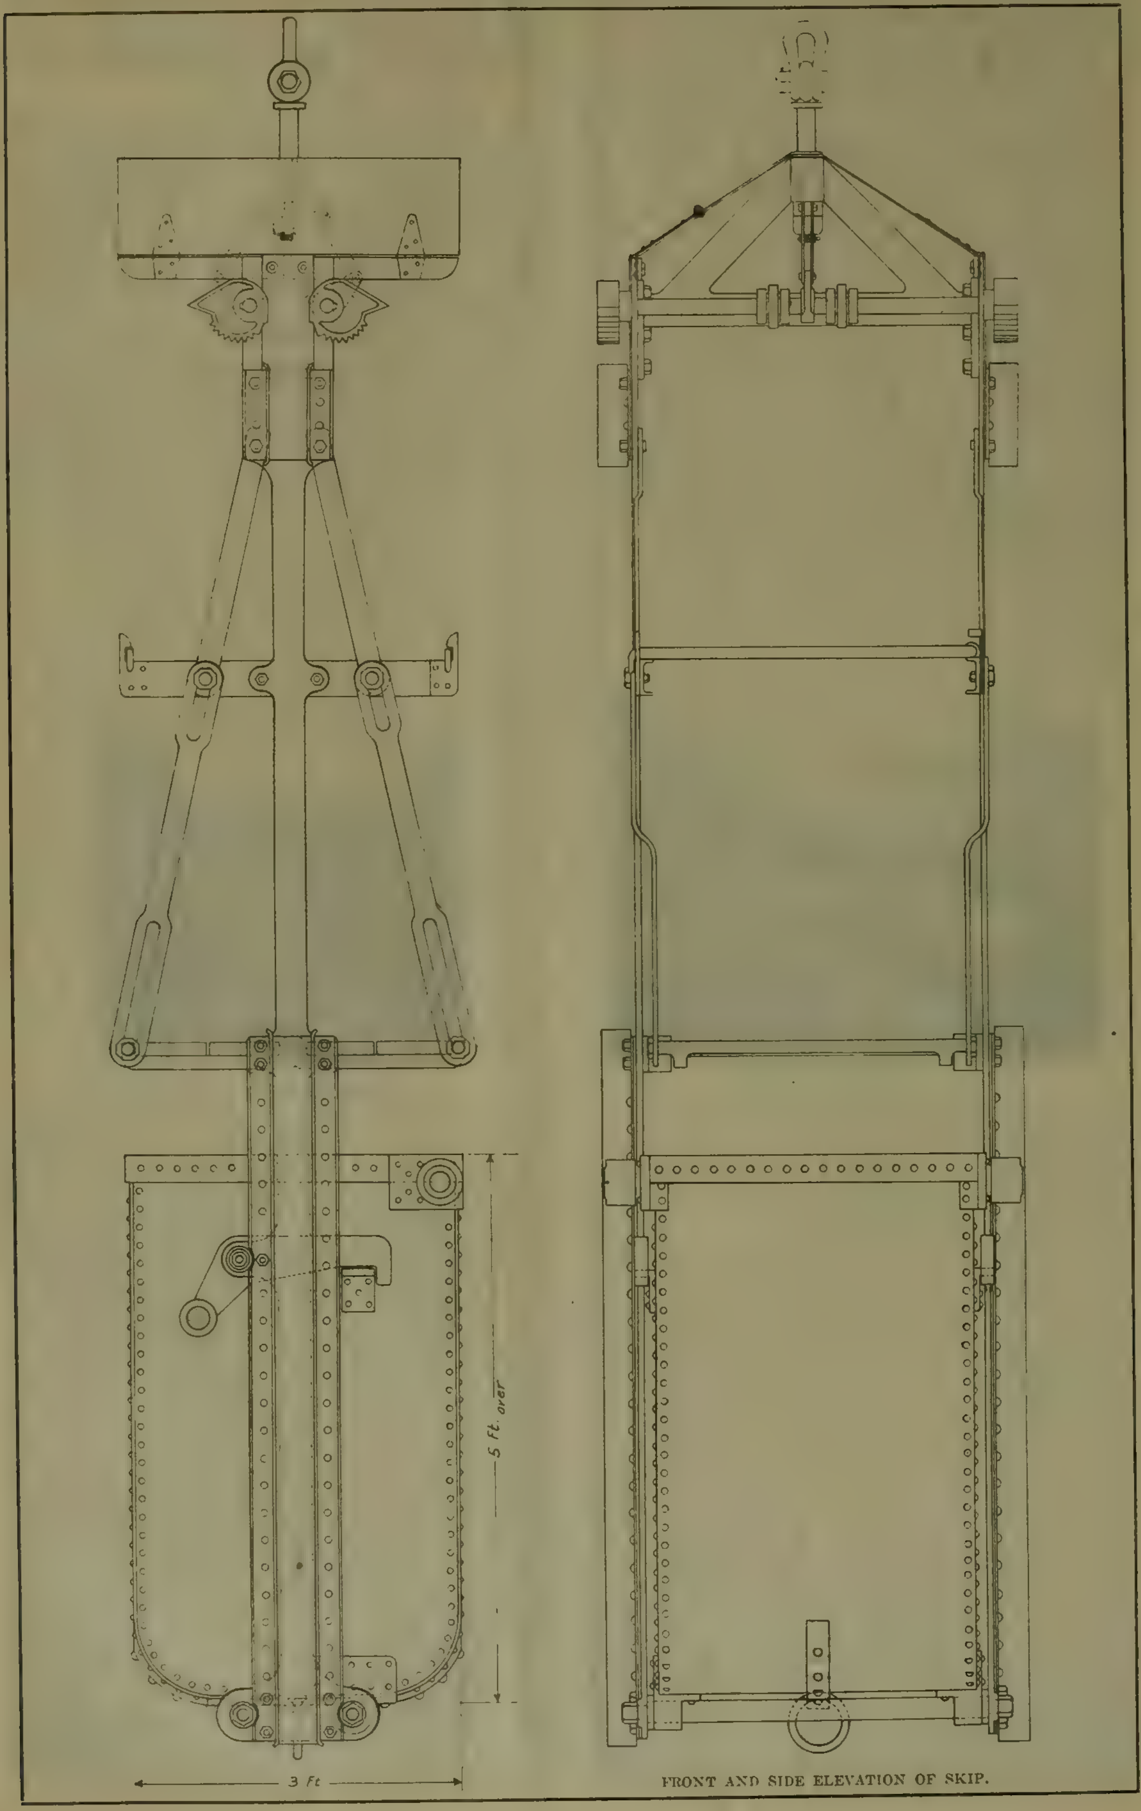
From the beginning of active mining operations in the Lake City district there have been smelters and lixiviation plants, which, between them, have treated much of the ore from the Lake City district and some from the Silverton district with doubtful success. Because of the historic interest connected with the early operations in the milling and smelting of ores from this region, a few lines will be devoted to that subject.

On October 31, 1877, the Ocean Wave smelter turned out its first lot of base bullion, about 10,000 lb. The works were equipped with two roasting furnaces and one stack and had a roasting capacity of about 15 tons per day. First charcoal and later coke from Trinidad was used for fuel. Crooke's smelter was also in operation at this time, although details of its equipment are not at hand. It is said to have shipped 300 tons, worth $48,000, during the year 1877. Its slag dump is reported to have been twice reworked with profit. The Van Gieson Lixiviation Works were in successful operation at an early day and are reported to have had an output of $35,000 in silver bars during the fall of the year 1877. The product ranged from 850 to 925 in fineness. Other smelters and other lixiviation plants existed, but descriptions of them are unnecessary.

The smelters which have received most of the ore from the Lake City district have been the Omaha and Grant smelters of Denver, Colorado, the Eilers plant at Pueblo, Colorado, and the Ohio and Colorado smelter at Salida, Colorado. At times other smelters in the State have received consignments from this area, but the majority has gone to the above-mentioned plants. The freight charges per ton would probably average from $5 to $8 to Salida and Pueblo. The treatment charges plus the cost of mining and shipping will run from $10 to $15 per ton in the Lake City district, so that under existing mining conditions it will hardly pay to work smelting ore running under $20 per ton. With concentration, however, a much lower grade of ore can be mined and milled with profit. The Hidden Treasure, for example, mined and milled $9 ore at a profit. The Golden Fleece milled $12 ore, saving 65% of the value, at a total cost for mining and milling of about $5 per ton.

ALPINE GULCH, NEAR LAKE CITY.

On the other hand, the processes employed by some of the mills have not proved to be suited to the kind of ore treated, and a large part of the valuable metals was carried into the tailing, several tailing dumps having been worked at a fair profit by various methods of lixiviation. The tetrahedrite, most of which is argentiferous, has a specific gravity of only 4.5, and when treated with galena, whose specific gravity is 7.5, it is lost by the same process which saves the lead sulphide. Galena is less brittle than tetrahedrite and does not slime so readily, so that after the ore is crushed and sent through sizers to the tables the galena is easily separated from the rest, and the gray copper, being brittle and of rather low specific gravity compared with the commonly associated minerals, is either left in close association with the gangue or lost in the slime.



FRONT AND SIDE ELEVATION OF SKIP.

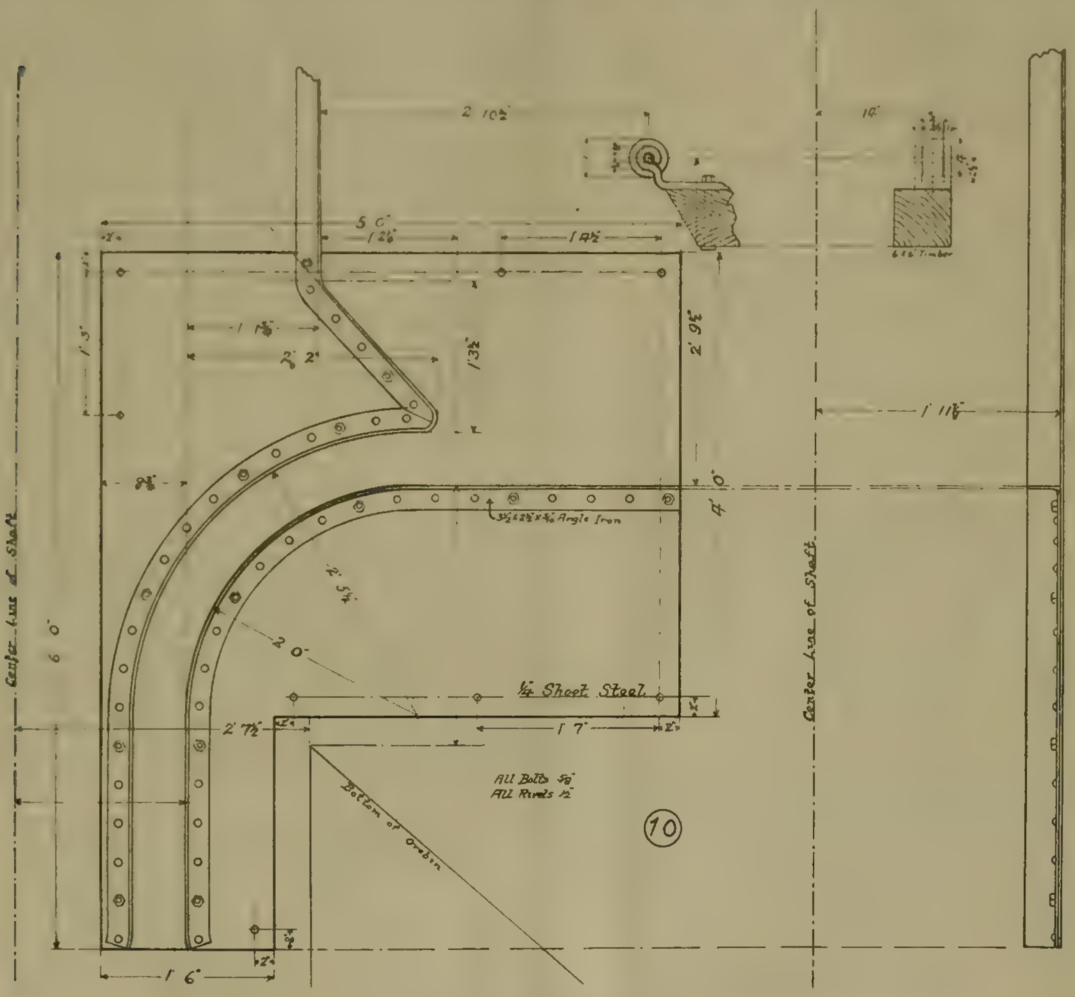
Skip for a Vertical Shaft

A novel and very satisfactory skip for vertical shafts has been designed by Willis Lawrence, formerly general manager for the Florence mine at Goldfield. Two of these skips, working in counterbalance, each having a capacity of 45 cu. ft., have now been in operation a year in the Florence shaft. Thus far no repair work has been done on them and they have required practically no attention from the master mechanic. The two skips, which weigh approximately one ton each, were built entirely at the mine. They are made up of solid forgings and riveted, so that there are no bolts to work loose.

The most novel feature of this skip is a substantial platform above the skip-body, so arranged that either half of it can be folded back out of the way when hoisting ore or waste, so that it does not interfere with loading the skip from chutes at the underground ore-pockets. This is made of 1½ by 2½-in. steel and is capable of carrying a load of two or three tons. For the lowering of men, steel, and other supplies it is of the greatest service. The details of the construction, showing how the platform folds up so as to occupy a minimum of space, yet allowing ready folding or letting down, can be seen from the front and side elevations given on the opposite page.

A second important feature is the roller which prevents the skip from descending the shaft in an inverted position after being overwound. The details of this device are shown on the drawing above, where the dimensions are also given. This roller works against a steel wearing plate, placed on the inside of the skip and either can be readily replaced when it finally becomes worn. The device is much more satisfactory than the older type of hook employed on the skips used in vertical shafts at Butte and elsewhere.

Other important features of this type of skip are the guide-shoes and the wearing plate. The guide-shoe, made from a plate with two angles bolted to it, is continuous from the platform level to the bottom of the skip, thus preventing fragments of rock or ore from becoming lodged between the guide and guide-shoe during the loading of the skip. A wearing plate is placed against the side of the skip opposite the loading chute to take up the wear resulting from the impact of the large pieces of ore and rock. Other details of the construction can be seen in the drawings.



DETAIL DRAWING OF SKIP DUMP.

In working underground it is necessary to have all openings wide enough to give sufficient elbow room to work to advantage, but the width is independent of the width of the vein. To illustrate the effect of this, if the minimum working width is 50 in., and the vein is 1 in. wide, then the proportion of ore to barren rock will be as 1 to 49. Supposing, however, the vein is 10 in. wide, this proportion will be reduced to 10 to 40, or as 1 to 4. Since the work done must be paid for by the value of the ore obtained, it thus follows that a narrow vein is worked under a very heavy handicap. If the veins are short, or pinch and swell suddenly, so that a lot of unprofitable work has to be done in finding or in following the orebodies, this gives a similar and additional handicap, so that where a vein is both narrow and irregular the chances for profitable working are but slight unless the vein is rich.

Mining Engineers in Japan

Editorial Correspondence

Since landing at Yokohama, November 3, the party of American mining engineers now visiting Japan has been made to feel in every possible way that its members are in the hands of their friends. There has been a constant round of entertainment and sight-seeing at every point. Elaborate arrangements have been made for the comfort and pleasure of the guests. At Yokohama itself the party was met at the Grand Hotel by a committee from the Chamber of Commerce, and after speeches of welcome were presented with beautiful badges, after which there was a ricksha ride to the principal points of interest in the native city. After luncheon at the hotel, given by the local committee, the party was taken to the City Hall, where the members were received by the Mayor and city officials. Following this, a band of geishas, elaborately dressed, sang the 'harvest song' in the street before the building, and, after tea, the party was taken to the waiting train. This entertainment at Yokohama was but the prelude to that at Tokio, Kioto, Nara, Miyajima, and other cities visited. At Tokio the engineers and their ladies were guests at an elaborate ball given in honor of the Emperor's birthday by Baron Uchida, the new Minister of Foreign Affairs. The official residence of the Minister had been enlarged for the occasion by the addition of a number of beautiful rooms, including a smoking room made by roofing in and surrounding a part of the garden. The effect was excellent, and in the brilliant and cosmopolitan throng attending the ball the engineers met friends from all parts of the world. Baron Uchida, as recent Minister to the United States, and the Baroness, a graduate of Vassar, were especially gracious to the Americans. The following day the party was taken through the University and art exhibition, to a crysanthemum show, and given a luncheon at Hotel Seiyoken in Uyeno Park by the City of Tokio, the day closing with an elaborate dinner at the Imperial Hotel, given by the local committee and presided over by Baron Shibusawa, with Viscount Kaneko as toastmaster. Sunday morning visits were made to the War museum and the Imperial gardens, followed by an elaborate luncheon in Japanese style, given at the Maple club in behalf of the Mining Institute of Japan by W. Watanabe, the director of the Engineering College of the University. As this was the first opportunity most of the visitors had had to see a real Japanese house and to taste Japanese fare, it was particularly appreciated. Following the luncheon a troup of geisha girls performed a number of the ancient symbolic dances. Later in the afternoon, at the Mitsui club, the Minister of Agriculture and Commerce received the party and gave an elaborate tea. In the rooms of this beautiful club an exhibit of pearls grown by careful culture was shown; an exhibition of the care and skill with which the Japanese are protecting ancient industries. There was also a ceramic exhibit, and on the lawn a group of workmen made small pieces of pottery for the visitors. Each selected a piece, which was then decorated and burned. Most of the Americans were extremely awkward in pottery decoration, but practically all the Japanese gentlemen and ladies handled the brush as well as the workmen.

Sunday evening the party left for Kioto, traveling on a special train of sleeping and dining cars, and finding the service excellent despite the unusual arrangement of the cars made necessary by the narrow gauge of the railway. As an example of the detailed care taken in handling the party it may be noted that the menus in the dining car, as elsewhere, were headed by the flags of Japan and the United States and that each menu was an artistic bit of color work. Interpreters, officials, and others were abundant, but some laughable misunderstandings occurred none the less. One young lady having ordered 'eggs over' and receiving eggs fried on one side, was disposed to insist. The waiter, doing his best to accommodate her, hunted up a knife and deftly turned the eggs in her presence. It has been hard, however, to find enough such misunderstandings to make a good story. At Kioto it was raining, so that the elaborate decorations arranged to greet the visitors were largely spoiled. The band, however, bravely persisted in playing 'Star Spangled Banner' as the rickshas came up to the hotel. For once the Americans were unable to stand and properly acknowledge the courtesy. Tuesday was a clear day and was a busy one, as visits were made to the Imperial palace, the Shogun's palace, the Golden Pavilion, various temples, and the University. At the last, as at Tokio, modern and ample equipment, and an able force of instructors were evident. Among the professors many old friends and schoolmates were recognized, and English, French, and German greetings were heard on every side. Of the Universities and their men more will be said at another time. Tuesday evening the party was entertained at dinner in the new commercial museum by the City of Kioto, the acting Mayor presiding. Aside from the excellent dinner, there was an exhibit of flower arrangement and a series of geisha dances. Here, as at Tokio, a number of Japanese ladies as well as gentlemen, were present to greet the party. Wednesday, November 8, was spent at Nara among the beautiful maples and temples, and as elsewhere a tea was given by the City to the visitors. This time the function was held in a beautiful hall in one of the parks, built and maintained for entertainment of guests of the city. After dinner at Kobe the party embarked on the *Umegaka Maru*, a steamer built by popular subscription and presented the Nation for use in time of war as a fast scout cruiser. In time of peace it performs the more prosaic duty of carrying passengers from Shimonoseki to Fusan from which service it was withdrawn and especially fitted for the use of the engineers in traveling through the Inland sea. It is a most comfortable boat on which not only excellent meals were furnished but flowers as well were distributed. Shisaka island, the seat of the Sumitomo smelting works, was reached at nine the next morning. While the ladies visited the hospital and schools, the engineers were taken through the smelter where the ore from the Besshi mine is reduced. The process was explained in detail later in the day by Keijiro Nakamura, the superintendent, who is traveling with the party. It involves pyritic smelting and stall-roasting, though pot-roasting has just been introduced. The works are modern and complete in every particular. More complete details will be reserved for a later letter. Friday was spent at Miyajima, one of the most beautiful spots in Japan, from which this letter is written. Saturday is to include a visit to the Imperial Steel Works.

Card Index System for Drawings

By P. B. McDonald

Drawings, maps, tracings, and blue-prints can be conveniently filed in a set of drawers, where each drawer is lettered and reserved for one or two subjects; thus one drawer holds underground maps, another pump data, and another plans for buildings. In each drawer the drawings are numbered from one up, thus, L-1 or M-1. Also, another number is put upon each drawing which is its chronological number, taking the drawings as a whole; thus a drawing is spoken of as 'No. 421, Index M-13.' Two sets of index cards are kept; one set is kept in the chronological order of the drawing, and each card tells the subject, the index, the date, scale, and draughtsman, of one drawing. The other set may be on differently colored cards, one color for maps and geological subjects, and one for mechanical data; the division is into subjects, such as, 'Head-frames,' 'Tram-cars,' 'Rock-drill parts,' and one card may represent several drawings referring to one subject.

If it is desired to look up a drawing made some time ago, it is usual to refer to the cards representing subjects and find the drawer and index number; if the drawing has been made lately, reference is usually had to the chronological set, where a glance at the last few cards gives the information. As soon as a drawing is started it should be given a number and index with a card in the chronological set; later it can be posted in the set of subjects.

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Is 'Cheap' Labor Economical?

The Editor:

Sir—I read with considerable interest the editorial in your issue of November 18, headed, 'Is 'Cheap' Labor Economical?' This is a question about which all kinds of opinions are held, and I dare say that a discussion thereon will be varied. I have had experience with 'cheap' labor in different parts of the world, with the numerous tribes of southern and central Africa, with Chinese, with Indian coolies, and with peons.

It is interesting to analyze the causes for the sometimes high cost of 'cheap' labor. Take South Africa as an instance, the Rand in particular. There the Kaffir labor has never had any unrestricted chance to show its highest efficiency. Were the economic the only side of the question, and it political and social aspects did not come into the South African labor problem, there is no doubt but that Kaffir labor would make a far better showing than at the present time. The future destiny of South Africa lies in a choice between a country like India, with only a handful of white men, and a country like the United States, where the white race is growing stronger and stronger and the colored race of less importance.

It is because of this political aspect that the legislators of the Transvaal have protected white labor to a certain extent by means of stringent laws, prohibiting the Kaffirs from doing what is called the 'white man's work.' For instance, it is against the law for them to run a large hoisting engine; it is also against the law for them to carry on blasting operations. The reason for these laws in the Transvaal is, not that the Kaffir cannot be trained to do this work, but that it is necessary to protect the white race from 'cheap' labor. A few years ago there was a serious strike of the white employees on the Rand, and for some weeks the mines were run with scarcely any white men. The change was too sudden, but it demonstrated what could be done with Kaffir and Chinese labor on the Rand if there were few or no restrictions. No one wants to see a second India in South Africa, and the people there are perfectly right to protect white labor; but the fact remains that, judging from a purely economic view, 'cheap' labor in South Africa has never had the chance to show its highest efficiency.

The experience with the Chinese on the Rand shows the importance of organization and direction when 'cheap' labor was employed. The burden of responsibility of the 'cheap' labor on the manager is greater than when he has charge of skilled labor. Economically the Chinese on the Rand were a great success and proved that 'cheap' labor is satisfactory.

In central Africa I found that the very low efficiency of native labor was due as much to the carelessness of the white management as to the black men themselves. Of course, in this section of the world, 'cheap' labor suffers from the drawback of a bad climate as compared with South Africa.

When we consider the peons, we find that the chief cause of their inefficiency is their awful native drinks, *tequila* and *mezcal*. If it were possible to introduce in Spanish America the Transvaal law prohibiting the sale of intoxicating liquors to laborers, the efficiency in that part of the world could be raised very materially. By putting so-called 'cheap' labor on contract and thus giving them an incentive for extra effort, I have been able to accomplish results that could not be beaten by any 'dear' labor in the world. The problem in all mining countries today, whether using 'cheap' or 'dear' labor, is how to increase the efficiency of the labor. Possibly discussion such as this will bring out points to help in this most important problem.

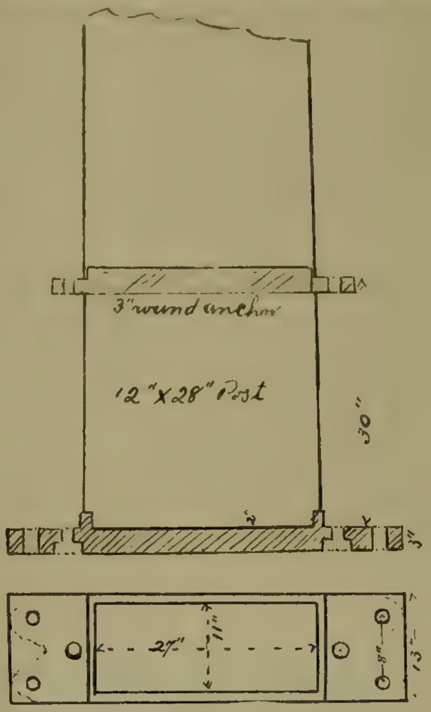
T. Lane Carter.

Chicago, November 25.

Battery-Post Shoes

The Editor:

Sir—There have been several descriptions of battery post shoes in your journal, and I wish to add a description of a shoe that has answered every requirement, and is lighter than those described, but heavy enough for the purpose. The battery posts anchored in these shoes have so little movement that the hand held at the base of the post can feel hardly any vibration. In the first set constructed here the hold-down bolts were 1¼-in. diameter and have never broken, but I decided on a stronger bolt for the next set, so ordered a 1½-in. bolt. The sole-plates are held down to the concrete with four 1½-in. bolts 3 ft. long, the lower end riveted in a cast-iron pocket washer.



A GOOD BATTERY-POST SHOE.

South Pasadena, November 20.

The State Mining Bureau

The Editor:

Sir—I wish to thank you for your editorial on the State Mining Bureau, in the issue of December 2, and for the valuable suggestions therein contained. I desire to say a few words regarding this institution, and to outline briefly some of the things it is hoped to be able to accomplish. I also wish to appeal to the miners of the State to give me their hearty support, for much depends on them.

The State Mining Bureau of California was created by an act of the twenty-third legislature, passed April 16, 1880. This act also created the office of State Mineralogist. The institution existed for a period of about thirteen years under the original act. A second act was passed March 23, 1893, which was similar to the original act. The act states clearly the purposes for which the Bureau was created, and it is the purpose of the present State Mineralogist to carry out, as far as possible, the requirements of the act, both in its letter and its spirit. To my mind, the main purpose of the State Mining Bureau is, not only to collect and publish statistical data of the mineral industry of the

State, as required by law, but to aid in every possible legitimate way the development of the mineral resources of California and to invite the attention of foreign as well as local capital to the vast possibilities of the State in the development of its mines, quarries, and mineral deposits. According to the latest statistical bulletin issued by the Mining Bureau, the mineral output of California for the year 1910 was over $88,000,000. Notwithstanding the magnitude of this production, I believe it can be materially increased. The mining and preparation of structural materials; of mineral salts, and of non-metallic substances is undoubtedly capable of large augmentation, though this expansion is, to a great extent, dependent on the rate of increase of population and the general upbuilding of the State, and to a lesser extent on the exportation of such materials from California to neighboring States and foreign countries. That the production of metallic minerals is susceptible of far greater development I am sure. Not all of the profitable gold mines have been developed, nor even all of them discovered, by any means. There is still a great future for gold mining in California. There remain many promising opportunities on the great Mother Lode, as well as on the East Lode, and in that mineral belt which skirts the foot-hills a few miles west of the Mother Lode. Of the great mineral zone that traverses the region of the high Sierra comparatively little is known. That region has been almost wholly neglected for more than twenty-five years. The great advance in knowledge of mining and metallurgy during the past two decades brings within the range of commercial possibility ore deposits in that region which were in early days unprofitable. What is most needed in that field is capital in the hands of men who are accustomed to the conditions obtaining there. The California miner has been reared in the foot-hills amid orchards, meadows, and vineyards. The majestic snow-clad peaks of the Sierra Nevada "do not appeal to him" as a land of promise. To the average miner of Colorado such conditions are by no means prohibitive—he has come to expect nothing else in the region of high mountains to which he has long been accustomed. Deep snows, long winters, fierce winds, and isolation have no terrors for him, if only the veins possess the elements of commercial success. The lack of convenient transportation is at present the principal drawback to the rapid development of this mineral province, but this can and will, I believe, be overcome, and probably within a very few years.

There still exist many, doubtless a surprising number, of what may be considered most promising opportunities in the equipment, development, and operation of gravel drift mines in the ancient rivers of the State. The desert regions, too, have for the most part been only superficially explored and there still remain many valuable mineral deposits to be worked in those fields. These include copper, silver, lead, zinc, and iron, as well as the ores of gold. The saline deposits are of great value, as has already been determined, but they have only been partly explored, and without doubt many important discoveries will yet be made.

The large profits won in successful mining have rendered the mineral industry an attractive field for dishonest promotion. Unfortunately the laws of the State are not, as yet, adequate properly to protect the public from the pernicious activities of fraudulent promoters. That the stifling of dishonest mining schemes hurts legitimate mining I do not believe, and it is hoped that legislation will soon be enacted by the California legislature which will afford all the protection to the mineral industry that is given to other lines of business. In the meantime the Federal laws afford protection sufficient to reach many of the more flagrant cases that may come to the notice of the State Mining Bureau, and these existing laws will be invoked to put a stop to the sale in California of shares in 'fake' mining enterprises, whether the property be situated within the State or elsewhere. It is supposed that there is a surprisingly large number of such companies now doing business in this State, and it is proposed to put an end to the sale of shares in such concerns through the untruthful presentation of the facts. Frequently new mining enterprises involve a far greater financial risk than is found in most other new ventures. In such cases the promotion literature should state the truth, whereas, usually, quite the reverse is the practice. It is extremely interesting, for instance, to read in a handsomely printed prospectus, that a certain mining company owns property in which there is a 12-ft. vein of ore assaying $200 per ton, and stock in the enterprise is being offered at a surprisingly low figure, but it would certainly be much more interesting and important if it were true. What is the outlook for the investor in the stock of this company if it has no ore in the property that will yield a profit under any circumstances? It requires but one guess.

From time to time announcement is made in the daily press of phenomenal discoveries of valuable mineral deposits in isolated places, and the alleged discoverers send broadcast statements calculated to attract large numbers of men, and women, too, to the locality. It comes within the scope of the duties of the State Mineralogist to promptly investigate such alleged discoveries, and to publish the facts officially. In the event of the reported discoveries being authentic it is hoped that much good will result from such publication, and if they are found to be otherwise, then surely much good must result from an official statement to that effect, for it would prevent many who could ill afford the expense of such an expedition from stampeding to a worthless camp.

It will be the purpose to keep abreast of the constant advance in mining and metallurgical methods, and in construction, by the publication of bulletins on these subjects as often as the situation seems to warrant. In short, it will be the chief aim of the State Mining Bureau to collect and publish useful and accurate information on all branches of the mineral industry in California, and to give publicity to such matters as promptly as possible—principally through the medium of official bulletins, and when necessary, by means of the technical and daily press.

A great International Exposition is to be held at San Francisco in 1915. Only a little over three years remains within which to prepare for this history-making event. California has the materials for presenting a splendid mineral exhibit at the Exposition, and that such an exhibit will be made by the State goes without saying. It is hoped to make it the most complete, attractive, and representative exhibit of the kind ever made by any State at any exposition.

I have outlined briefly some of the things it seems to me desirable to undertake and to carry out, but the State Mineralogist can accomplish little without the earnest and hearty coöperation of all the mine managers, superintendents, and mine owners, and of the working miners as well. Much is expected of this administration of the State's department of mines, but in order to make the State Mining Bureau properly subserve the purposes for which it was created and is maintained, all must lend a helping hand. In conclusion I only wish to add that if the mining men of California will give me their aid it is hoped that the State Mining Bureau will become one of the most useful and most necessary of all of the institutions of its kind in the world.

William H. Storms.

State Mining Bureau,
San Francisco, December 4.

Laramie Tunnel Figures.

The following interesting figures relating to work on a 7½ by 9½-ft. tunnel in hard rock driven in Colorado, are given by D. W. Brunton in a paper read before the American Institute of Mining Engineers:

1911.	Feet completed.	No. of holes.	Lin. ft. holes.	Av. lin. ft. holes, per day.	Sticks powder.	Cars débris.
March	653	1,965	14,330	154	14,808	4,983
April	583	1,759	12.510	139	16,171	4,765
May	635	1.985	15.263	164	18,311	5,156

Concentrates

Most of these are in reply to questions received by mail Our readers are invited to ask questions and give information dealing with the practice of mining milling and smelting

AN excellent red lead cement for face joints is made of equal parts of red lead and white lead mixed with linseed oil to the proper consistence.

TO drill chilled cast iron, first draw the chill. This is done by laying the piece on the forge, covering the spot to be drilled with sulphur, and working the bellows slowly until the sulphur is burned off. Then proceed with the drilling.

LIME is burned with a number of different fuels. Coal is used extensively by plants in the United States at present, followed in order by wood, coke, producer gas, natural gas, and oil. A large variety of mixtures is also employed, such as coal and coke, coal and wood, coke and wood, coke and shavings, and shavings and manure.

NATIVE COPPER is chiefly obtained from the mines of the Lake Superior region, though the mines at Coro-Coro, in Bolivia, produce some native metal. Though native copper is found in Arizona, California, and, to a limited extent, some other American localities, it is never mined for itself alone, nor does it constitute any notable percentage of the copper output except in the Lake region.

PETROLEUM has been found in Alaska, and while there has been practically no production, it is not impossible, according to the United States Geological Survey, that commercial pools may be found. Oil seepages occur on the west shore of Cook inlet, on the east side of the Alaska Peninsula, and on Controller bay, all close to tidewater, and hence capable of cheap development.

ETCHING of names or figures upon steel articles can easily be done with the aid of a lacquer made of 2 parts of powdered asphalt, 1 part resin, 1½ parts wax, and a little tallow. The surface to be etched is first covered with a thin coating of this, and after the design has been cut through the lacquer, the etching may be done by the use of nitric, acetic, or tartaric acid.

BLASTING caps contain a charge of fulminate of mercury, one of the quickest and most powerful explosives known, extremely sensitive to heat, friction, or shock, and very poisonous. The charge in the cap can be easily exploded by scratching it with a pin or by twisting a piece of fuse around it vigorously. The explosion of a quadruple cap will blow a hole through an inch pine board or amputate several fingers from the hand that holds it. Therefore, handle caps carefully. Never under any circumstances attempt to remove the explosive, nor cut caps with a knife.

TEMPERING small taps may be done as follows: Place an iron vessel with a capacity of about one gallon in a gas-furnace and put enough lead into it to make it about three-fourths full when melted. Bring this to a suitable degree of heat and cover with charcoal to the depth of one-fourth inch, the charcoal preventing the lead from clinging to the threads. Then insert the taps to a sufficient depth to allow them to become heated a little beyond the threads and leave them in the lead only a few seconds, then remove and plunge them into the water bath. After they are hardened put them into a perforated basket and draw in an oil furnace provided with a thermometer.

RUSTING of iron is accelerated by any combination of circumstances which tends to keep the metal moist while allowing free access of air to it. For this reason, when rusting is once started it progresses rapidly, as the coating of rust has this effect. Organic matter in the soil will hasten the rusting of buried iron and steel by the organic acids resulting from its decay. Sea water rapidly corrodes steel if its temperature is below 55°F., but above that temperature is less corrosive than pure water. Rusting is best prevented by covering the surface of iron and steel with some substance which will prevent air and moisture reaching the metal.

THE United States Geological Survey formerly made field and laboratory studies of many kinds of sand and gravel in localities where Federal buildings were in course of construction. These studies have shown great variations in the quality of sand and gravel used at different places for making concrete. Some contractors contend that run-of-bank sand and gravel are the best for making concrete, but this contention is generally not sustained by practical trials and experiments. The most desirable material is that which is free from clay, loam, or dust. Mica, pyrite, or limonite also is objectionable, if present in large quantity. A coating of dust on gravel presents its proper contact with cement, so that such pebbles are easily broken out of the concrete.

GRAPHITE imported into the United States comes mainly from Ceylon and Mexico. It is significant to compare the total value of the imports in 1910, $1,872,592, with the total value of the domestic product, both natural and artificial, which was $1,322,176. The domestic demand for graphite and graphite products is undoubtedly increasing, and it is encouraging to note that this demand is being met principally by increased domestic production rather than by increased importation. Domestic flake graphite is replacing the Ceylon graphite to some extent in the manufacture of crucibles for the metal industries. There appears to be no reason why this replacement should not increase, for in Germany flake graphite similar to much of the American product has for generations been successfully used for this purpose.

PLACERS upon unsurveyed land should conform as nearly as practicable to the system of public-land surveys and the rectangular subdivisions of such surveys, by making the location as nearly as rectangular in form, compact, and with east-west and north-south bounding lines as is reasonably practicable. The Land Department considers claims satisfactory when those of one or two persons can be entirely included within a square 40-acre tract; when a claim located by three or four persons can be entirely included in two, square, 40-acre tracts placed end to end; when a claim located by five or six persons can be entirely included in three, square, 40-acre tracts; or a claim located by seven or eight persons can be entirely included in four, square, 40-acre tracts; but it is not intended that the 40-acre tracts shall necessarily have east-west and north-south boundaries.

ZINC DUST is an impalpable powder which forms in the distillation of zinc when the zinc vapor is cooled too rapidly in the condensers or is diluted by too large a volume of other gas. It may constitute a large proportion of the metallic zinc obtained in electrothermic zinc smelting, but in ordinary retort smelting it usually amounts to between 3 and 10% of the reduced zinc. The powder consists of metallic zinc, with about 10% zinc oxide, which probably exists as a film surrounding the metallic particles. These particles cannot be made to coalesce by heating unless under great pressure, but must be again vaporized and condensed. Marketable zinc dust must not contain more than 10% of zinc oxide and must pass through a screen of 100 meshes to the inch. Zinc dust differs from metallic zinc in other physical properties, such as rapid oxidation, absorption of hydrogen, and generally greater chemical activity, resulting at times in spontaneous combustion or explosion. These properties are believed by Sang to be due to conditions of stress resulting from rapid solidification, somewhat analogous to the condition in a Prince Rupert's drop.

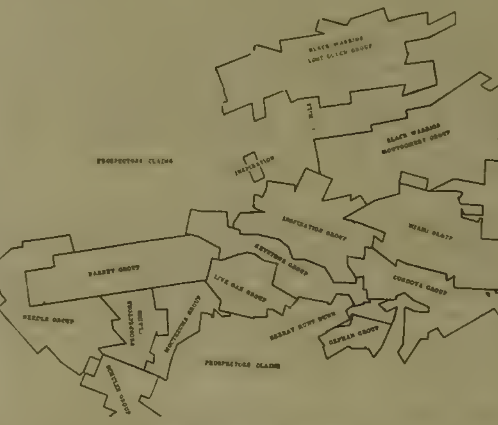
NEW YORK

European War Scare Real Cause of Copper Surplus Decrease.—Cole-Ryan Interests Enter Porphyry Field.—Lewisohns Are Leaving Mining.—Rice's 'Squawk-Book'.—General Notes.

While there is a strong effort on foot to revive interest in precious-metal mining—that is, the interest of that part of the public which makes it a rule to look for ground-floor offerings or first prices on public flotations—nevertheless, the coppers and the copper situation have held the centre of the stage, with the spot-light playing very vividly. There has been an advance in copper metal, and export shipments have run high: in many quarters the feeling was expressed that there was not a change in business conditions, either at home or abroad, that would justify a boom in copper, and there have been many queries as to what was or is the basis for such a movement. One feature, which has been pointed out repeatedly as making for improved conditions, has been the decrease in the visible supply abroad. It seems not to have occurred to those who seemed anxious to make the most of the apparent improvement, that this shrinkage in the world's visible supply of red metal was undoubtedly due to the low-hanging war cloud in Europe. The British Parliament has just listened to the Secretary of Foreign Affairs while he explained how low this cloud was really hanging during a part of the recent unpleasantness between France and Germany. That the various governments abroad were making every possible preparation for immediate war is now well known: that such preparations should have included large orders for copper for cartridges is surely a matter of course. From the recent admissions that France and Germany were on the very brink of actual hostilities, that Turkey and Italy are even now engaged in warfare, it is not hard to draw a reasonable deduction as to where the copper went, that left the much-talked-of shrinkage in accumulated stocks. This spasmodic demand is hardly such a use of copper as will serve for a foundation for the upward movement that has already taken place, to say nothing of further advances in the face of prevailing conditions. The metal was worked up to 13¼c. during the week, but looks much quieter now, and the reaction appears to be at hand. Undoubtedly the Producers' report for November will show a substantial decrease in the surplus, but it is doubtful if it will show that American buyers have come into the market to cover their needs for any length of time in the future.

Of probably more real importance as to the future of the copper market in this country is the entry of the Cole-Ryan interests into the porphyry field. In drawing comparisons and making estimates it has, for some months, been the rule to consider the Guggenheim group of low-grade milling coppers upon the one hand and the mines of the Amalgamated Copper Co. upon the other, Butte being considered the typical deep-level mining district and the greatest group of copper properties of its class. Now it seems that the group of owners whose interests centre at Butte and who include, broadly, the Standard Oil Co., the Amalgamated Copper Co., the United Metals Selling Co., the International S. & R. Co. have in a measure capitulated to the new departure in copper mines and have determined to take a hand in developing some big low-cost production. John D. Ryan, president of the Amalgamated Copper Co., is credited with having purchased a controlling interest in the Live Oak Development Co. at $30 per share, which is equivalent to about $2,500,000 for the property on a basis of the present outstanding stock. There has been quite a little discussion of merger possibilities in the Miami district recently, and the present coming in of new factors has greatly revived interest in the area. Miami, Inspiration, and Live Oak are all adjoining properties, and it is looked upon as certain that further consolidations will follow. Not long ago there were some preliminary negotiations between the Thompson-Gunn interests, which control the Inspiration, and the General Development Co., which owns a majority in the Miami, but while the two properties are one by nature, the dividing line being an arbitrary one, the owners of the two portions could not get close enough together to really 'talk trade.' It is more than likely that one of the inducements which brings Mr. Ryan into the Miami field is the recent move of the American Smelting & Refining Co. in taking over the partly completed smelter of the Ray Consolidated and erecting an immense plant at Hayden, Arizona. The present move is in part simply to keep abreast of the growing opposition. The United Metals Selling Co. has seen the Guggenheim agency growing in power, handling each year more and more copper, and the business of copper production has, in a way, been made secondary to the factors which handle the ores after they leave the concentrator. No small part of the movements which have been made in copperdom during the past two or three years, have been due to the ambition to control both the smelting industry and the business of selling the metal. The minority interests in the Live Oak deal have been protected by an offer to take all stock deposited in bank in New York by December 7, at the same price as was paid for the control, $30 per share. In sending out this notice to the shareholders, Mr. Hovland, president of the Live Oak company, states that the Miami Copper Co. endeavored to buy the Live Oak at the same price that Mr. Ryan paid, its offer being in debentures of the Miami Copper Co., however, instead of cash.



PART OF GLOBE DISTRICT.

It is hinted in some quarters that the Lewisohns—Adolf Lewisohn and his associates—who control the General Development Co. and the Canadian Silver Mines Exploration Co., the former company controlling the Miami and the New Keystone copper properties and the latter controlling the Kerr Lake and the Wettlaufer, both silver properties in the Cobalt district, are getting out of their mining investments. Adolf Lewisohn and his brother Leonard, now several years deceased, were the founders and upbuilders of the United Metals Selling Co., and make it primarily the greatest copper brokerage firm in the world. The family has always been the dominant interest in Tennessee Copper, but recently a large block of Tennessee was taken over by banking interests, and it is probably true that the Lewisohn interests in the various properties which they control is not as large as it was two or three years ago. The Canadian company took up several properties in the new gold district of Porcupine, but, so far as known, is not now identified with the district in any way.

The Thompson-Gunn interests, which are the dominant factors in Inspiration, while considering that property as the most important one in process of development under their charge, while getting ready for the 5000-ton plant on the Inspiration, have brought the Mason Valley property at Yerington, Nevada, to the point of production, and the smelter is to be blown in during the current week. Mason Valley will add about 1,000,000 lb. to the monthly output.

The problem of the First National Copper Co. has resolved itself into a study of the demand for artificial fertilizers in the West. The fume troubles in which the First National became involved in Shasta county, California, precluded the possibility of handling the property at a profit; if, however, enough demand can be found to justify the addition of a sulphuric-acid plant, it is possible that the Balaklala may yet be operated at a profit. First National was at one time a member of the family of Thomas W. Lawson, of Boston, and it must be considered as natural that the mine should encounter all kinds of trouble thereafter. Nevada Utah, at one time starred in a most spectacular advertising campaign, in which Lawson lavished his most picturesque powers of description, has just been placed in the custody of a receiver, while Bay State Gas and Trinity Copper seem unobtrusively to have slipped into history without remark in any way upon their passing.

While spread-eagle advertising has not been much in evidence in the East since the most recent rise and fall of George Graham Rice, who is now on trial for running a bucket shop and using the mails for fraudulent purposes, there is a strong advertising campaign being made by means of Sunday supplements in behalf of Porcupine. Leading properties are being written up, and some of the brightest lights of the old days of Tonopah and Goldfield are making almost superhuman efforts to flirt with the calcium. The trial of George Graham Rice, B. H. Scheftels, and some of the minor associates is enlivened by the reading of the 'squawk book', which contained the complaints of those customers who kicked because they were unable to force deliveries of stock purchased.

Fred Hellmann is at South Lorrain, near Cobalt, Ontario, at the Wettlaufer property, to superintend the starting of the new mill, which is to handle the low-grade ores of the mine. Wettlaufer ships about two cars of high-grade ore and is paying dividends at the rate of 20% upon par, $1 per share. It is a striking commentary on the way the public has become educated to look upon mining dividends, that a property such as Wettlaufer should pay dividends at such a rate, with its productive career just begun, and yet sell below par. The market for the shares is about 85c., at which price it pays nearly 25% upon the investment.

The report of the Braden Copper Co., just issued, is very interesting, especially in its estimate of copper costs. Copper costs are figured at 7.4c., with possibilities of further reduction. This figure will give Braden an important place among the low-cost producers. Yukon Gold, another of the Guggenheim properties, cut its dividend distribution from 10c. quarterly to 7½c., reducing the rate from 8 to 6 per cent.

LONDON

East Rand Proprietary Report Published.—Future Dividends to Be 25% Instead of 40%.—H. Ross Skinner May Be Consulting Engineer for Company.—More About Camborne.

At last the official report of the committee appointed to investigate the shortage of gold at the East Rand Proprietary has been published. Unfortunately it is a very long one and the committee has not seen fit to give a synopsis or a shortly expressed opinion such as would be suitable for the average shareholder or speculator on this side of the world. The committee was an excellent one, consisting of a magistrate, H. O. Buckle, the managing director of the Premier Diamond Co., P. Ross Frames, and the Government mining engineer, R. N. Kotze. The combination of an administrator, a business man, and a mining engineer was singularly appropriate. The state of affairs was pretty well known before the committee was appointed, as I said in my letter sent a fortnight ago. The committee reports that the difficulty of keeping the yield of gold up to the required level to provide a 40% dividend had been a pressing one for longer than anybody had thought. It appears that as long ago as May 1909, E. H. Johnson, the consulting metallurgist, expostulated with the joint general managers for 'excessive clean-ups,' and that in December a year ago the condition became really serious. The fact is that gold habitually has been taken from the amalgamating plates, the solutions, and the zinc boxes, that really should have been left in the interests of efficiency. This abstraction, of course, was done only as a temporary expedient, as the managers really expected that the deficiency eventually would be made good by the mine. But a bank cashier falls sometimes into the same fatal state of mind, hoping that all will come right in the end, with the inevitable result that the evil day arrives nevertheless. The minute details of the case will not interest the public, so I will merely say that the net result is that in the future the capabilities of the mine in point of yield per ton will not be exaggerated, and that the shareholders must be content with 25% instead of 40%. This will be serious to investors who have paid inflated prices for the shares, but that cannot be helped. There is another aspect of the question which deserves notice. It appears that the shortage difficulty was kept a secret in some quarters where the people connected with the company had a right to know the full details. This suppression was made possible because the company had no consulting engineer. In this group each manager has complete control and is responsible only to the board. There is no consulting engineer whose general duty would be to keep in touch with the details of policy at each mine. All the other groups on the Rand, and in fact most English financial houses, have consulting engineers, and some even a staff of such. If the Farrar group had had such an organization, the worries besetting the managers of the East Rand Proprietary would have been shared by the consulting staff, and the board would have been told plainly and bluntly that their demands for a certain minimum yield and profit were impossible. It is rumored, but with what truth I am unable to say, that H. Ross Skinner has been asked to accept the position of consulting engineer. Mr. Skinner has done good work in this capacity for the Durban-Roodepoort and the Vogelstruis estates, two companies working in the west part of the Rand, and unconnected with any of the great 'houses.' One of the ultimate sequelae of this case will be the demand on the part of the shareholders in South African mines that African companies shall be registered in England. As it is, the boards of directors are in absolute control. The meetings of shareholders are farces as such, being attended by nobody but the directors and some of the staff to make a quorum. The shares are not held to any great extent in Africa, and probably more are owned in France and Germany than in England. "The meetings of shareholders ought to be held in some place where the shareholders can meet," as Abraham Lincoln would have said with his characteristic plain common-sense.

In my letter sent last week I referred at some length to the precarious condition of the Camborne Mining School, and I asked Cornishmen in all parts of the world to consider the advisability of subscribing liberally to an endowment fund. There are two aspects of this question that I ought to have referred to at the time, and I therefore make the present addenda. In the first place, the Government Education Office, when the consolidation of the various Cornish mining schools was effected two years ago, dubbed the new institution with a ridiculously expressed name. Who expects any dignity to accrue to a school whose name contains a word enclosed in parentheses? The name is as follows: 'School of Metalliferous Mining (Cornwall).' Fancy sending your boy to a school that has the most important word in parentheses! I can understand a fond parent endowing with a few million pounds a new university with junior forming part of its title, but that was the founder's business. But a public school under the control of alleged reasonable men ought to have been treated better. 'The Cornwall School of Mining' would have been appropriate. Surely at this time of day it is not necessary to include the word 'metalliferous,' for metalliferous has been the only mining in Cornwall for two thousand or perhaps four thousand years. However, such is the slowness of English thought that perhaps it was as well to include the word. I, as an Englishman, advised those responsible for the establishment of *The Mining Magazine* not to be in too great a hurry for the practical support of the public, for I know by experience that things move slowly here, and that patience is required even for the propagation of science and common-sense. But I must say that the necessity for describing the Camborne School in the way mentioned is 'the limit.' The other point to which I want to draw attention is the cavalier way in which the new principal, W. Fischer Wilkinson is treated. Personally I thought it was a great event when his services were secured, for he is a man of distinction, with experience in all parts of the world, especially South Africa. It is therefore a matter of regret, if not of disgust, to find the governors not booming him for all he is worth. Here is the *Cornish Post*, the paper published at Camborne, containing a miserable little advertisement of the School of Metalliferous Mining (Cornwall), with never a reference to Mr. Wilkinson. It's really too bad! I am informed that those in control of the school plan making him one of the 'governors.' This is a tardy recognition of the importance of his post and influence, but it is a very incomplete sort of justice. He that is responsible for the subjects taught and the method of teaching should have more to say than is the privilege of one out of twenty governors. More must yet be done to give an 'authority' on mining some authority in the school management. The first new stroke of policy required in order to put the Camborne Mining School on its legs is a due and just recognition of the value, ability, and importance of the teaching staff.

GLOBE, ARIZONA

Miami Concentrator to Have Fifth Unit in Operation This Month.—General News of the District.

B. B. Gottsberger, manager for the Miami Copper Co., states that the long delayed line-shafting has arrived and that the fifth unit of the concentrator should start early in December, bringing the daily production up to 2500 tons. The mill is now producing about 90 tons per day of concentrate averaging 41% copper. The concentrate is shipped to Cananea. The stopes in the northwestern part of the mine are beginning to produce. There are three stopes being opened up, one of which is producing. The cross-cut to the orebody from the main shaft, on the 570-ft. level is being advanced and is now over half way to the orebody. Installation of machinery in the power-house continues and the second Nordberg compressor has been shipped.

Development of the Live Oak continues steadily under the supervision of M. E. McCarthy, manager of the property. On the 800-ft. level in No. 2 shaft, a drift is being run in a northwesterly direction in ore reported to assay 3% copper. Driving on the ore is also being done on the fourth level from No. 1 shaft. Two churn-drills are now in operation near the western end of the property in the vicinity of No. 2 shaft. The latest official report places the developed tonnage at 19,000,000 tons of ore averaging 2.11% copper.

The experimental mill of the Inspiration Copper Co. has been started under the supervision of J. M. Callow and E. J. Harrison, and some radical departures from present milling practice are being tried out. Preliminary surveying continues and H. J. Wallace, one of the chief construction engineers, has arrived. Henry Krumb, consulting engineer, who is now at the mine, says that the main features of the construction program have been decided upon, but that there remain a few minor details to be settled. He thinks that construction will begin soon after the first of the year.

Hole No. 1 of the Southwestern Miami Development Co. is 1285 ft. deep and is still in ore, having penetrated the orebody at a depth of 1110 ft., making 175 ft. of ore thus far passed through. The hole is now being enlarged with an under-reamer so that the casing may be lowered and drilling continued. Work has been delayed recently by freezing weather.

High-grade silver ore is being mined by several groups of lessees on the Copper & Silver Zone group of claims, three miles east of Globe. In the old workings in an adit on the Old Ironsides claim, lessees have opened up 2½ ft. of ore reported to carry 100 oz. of silver per ton and 2% copper, the silver occurring as a chloride, or hornsilver. On the Copper Zone claim some narrow veins of lead-silver ore are being worked, the silver occurring in galena. On the Black Crown claim, a narrow vein of ore, reported to carry 40 to 80 oz. of silver per ton and a little copper, is being opened by a shaft. The group is considered to be a promising prospect.

Three men continue to keep the water out of the Summit mine and watch the property, but no word has yet been received by the stockholders as to the plans for reorganization or the future policy of the management. A piece of float running very high in gold was picked up about three miles north of Globe last week and has stimulated prospecting in that vicinity. The gold occurred as a telluride in weathered diabase.

The Copper Reef mine, twelve miles south of San Carlos, is employing about 20 men. The inclined shaft is being sunk and is now about 800 ft. deep. Cross-cutting is in progress on the 600-ft. level, but no ore has yet been found.

DENVER, COLORADO

Cripple Creek Drainage Adit Develops Large Flow.—Colburn Mill Starts.—Camp Bird Lessees to Operate Promising Blocks.—Rate War Closes U. S. R. & R. Plant.—General Notes.

The progress of the Cripple Creek drainage adit continues to be a leading item in Colorado mining affairs. On November 24 the Fuller cross-cut developed an additional flow of between 3000 and 4000 gal. of water per minute, making the outflow at the mouth of the tunnel about 9000 gal. per minute. At the intersection of this cross-cut with the C. K. & N. veins, some of the richest orebodies ever found in the El Paso company's ground were discovered, at a depth of 1350 ft. This is nearly 400 ft. deeper than the present lowest El Paso level. Work is still being continued in the main heading and in the Fuller drift of the drainage adit. Cripple Creek operators are naturally greatly pleased with the manner in which the district is being drained by the adit. The 1500-ft. level of the Portland mine is now entirely recovered.

CAMP BIRD MINE.

The Colburn mill, on the Ajax property at Victor, started on November 17, and after a constant two weeks' run, during which time all the parts of the mill were completely adjusted, the management is able to say that the plant is an unqualified success. A modified cyanide-treatment process is used. This plant makes a higher percentage of extraction than any other mill in Cripple Creek, and the operating expenses, per ton of ore treated, are probably lower. It is claimed that eventually the treatment cost in this mill will not exceed 90c. per ton. At present 150 tons per day is treated, and the plant will soon be handling its regular capacity of 200 tons per day. Only four men per shift are required to run the mill.

The famous old Camp Bird mine at Ouray, for nine years one of the largest gold producers in Colorado, is rapidly declining in production, and it is announced by the London office of the Camp Bird, Ltd., that operations in the property on company account will probably suspend on February 1, unless additional discoveries of ore are made in the meantime, which is not held to be likely. Lessees, at that time, will be granted privileges of operating the most promising blocks of ground. In the past nine years the mine has produced about $18,000,000, and has paid its English owners profits amounting to $7,500,000. The secretary of the company reports that for every £100 invested in the Camp Bird, the Englishmen have received £175 in dividends, and the £100 investment is now worth £150. During this year the profit will be about $750,000. The mill is at present running on a reduced tonnage.

J. D. Hawkins, president and general manager of the United States R. & R. Co., of Colorado City, has issued a circular to Cripple Creek operators stating that the plant will temporarily suspend operations, because of a decrease in ore shipments from Cripple Creek, which is the only source of supply for the mill. All existing ore contracts will be taken care of by the Golden Cycle company, operating a mill in the same city. The announcement further states that the operation of the plant will not be resumed "until conditions warrant". This reveals a phase in the milling industry of Cripple Creek that is far from satisfactory to the custom mill men. The rivalry for Cripple Creek ores has been keen for many months, and rate cutting has been resorted to in order to secure tonnage. Normally, the two Colorado City mills handle 40,000 tons of ore per month; about 26,000 tons by the Golden Cycle and 14,000 tons by the United States R. & R. plant. The latter has a capacity of 750 tons per day, so that it has been running at less than two-thirds capacity. While the output of the Cripple Creek mines is now greater than ever before, in tonnage, the increased milling facilities within the district have greatly decreased, the shipments going to outside plants. As it is not likely that the tonnage to Colorado City will ever increase, there is little prospect that the closed plant will resume in the near future.

The old Hill smelter at Ouray, idle many years, has been purchased by Thomas B. Crawford and associates of Denver, who are remodeling the plant with the intention of putting it into active operation shortly after the first of the year. Mr. Crawford owns the Indiana and other mines at Ouray, in which a considerable tonnage of ore lately has been developed. This and other properties in the locality are expected to furnish a supply of ore to keep the plant constantly running at its capacity of 50 tons per day. A lead furnace will be added.

Members of the Colorado Chapter of the American Mining Congress and the Denver Chamber of Commerce, at a joint meeting held Tuesday evening, November 28, adopted resolutions petitioning Congress to grant the national Bureau of Mines sufficient funds to construct and maintain a metallurgical testing station in Colorado. The problem of efficient methods of ore treatment has been bothering many operators in the State for months, particularly in Clear Creek and San Juan districts, where large bodies of complex ore of fair value are available, but are apparently not amenable to treatment by any of the methods now in vogue in Colorado.

KALGOORLIE, WESTERN AUSTRALIA

LABOR PARTY WINS IN ELECTION. — TRANSCONTINENTAL RAILROAD TO REACH MINERAL DISTRICTS. — PHTHISIS COMMISSION CONTINUES INVESTIGATION. — MINE PRODUCTION FOR SEPTEMBER.

The most interesting topics during the month of September were the State General Elections, and the proceedings of the Miners' Phthisis Commission. In the first business the contest was bitter and keen in the extreme, between the Liberal and Labor parties. The election resulted in the complete rout of the Liberal party, which had been in power for many years. Everybody was surprised, and the position at present is Labor 31, Liberal 15, with 4 more returns to come in at the end of October. Even the Minister for Mines was beaten, and in several agricultural districts Labor men got in easily. A Labor government held office for a few months some years ago; but it was a poorly organized and indifferent party. The present lot are level headed men, and many past abuses in all departments, some of which are connected with the mining industry, are sure to be rectified.

The Federal government, which is also a Labor party, is doing splendid work, and before these notes are in print, the Transcontinental Railway bill will be passed. This line, 1060 miles in length, is from Kalgoorlie to Port Agusta in South Australia, and connects with all the system of Australia. This line should be the means of opening up mineral bearing and pastoral country.

The Phthisis Commission has taken further evidence from doctors resident in the fields, general managers, mill superintendents, miners, and others who are in a position to speak. Some interesting evidence has been given on stoping, raising, driving, filling stopes, shoveling into trucks, filling same out of chutes, the use of respirators and sponges, underground sanitary conditions and the coöperation of men in this respect, temperatures, damping the ore, and so on. The opinion of some of the doctors was somewhat curious, and apparently they have not bothered much in the past on the question. Evidence was also given on the dust in dry-crushing plants, the percentage of moisture (1%) permissible in ball milling, the superiority of dry versus wet treatment in general extraction and profitableness, and the steps taken to minimize the evil. The Commission inspected the underground workings and mills of several mines. The general manager of the Great Boulder advocated a system of compulsory insurance, the employer, employee, and State each contributing.

Only about 4 in. of rain has fallen on the goldfields this season so far, and it is quite probable that the outside areas will be short before long, to the detriment of work generally. Last year we were 11 months without rain, and the outlook seems similar.

The gold yield from the State in September was valued at $2,540,000. The 12 mines comprising the local Water Trust used 32,131,000 gal. of water in August. Many millions of this total were used in sluicing away residue, by the Associated, Great Boulder, Kalgurli, Lake View & Star, Oroya Links, and South Kalgurli.

The Ivanhoe publishes its reserves as 1,010,297 tons averaging $10.62 per ton, these being distributed in the East, Middle, New, and Boulder lodes. Results from the Horse-Shoe, Lake View, and Oroya Links have much improved to what they have been for some time, heavy plant and development expenditure cutting into profits. The mills are now in full working order with improved and interesting results.

The principal mines returned as follows, in September:

Name.	Tonnage.	Value.	Profit.
Associated	9,626	$ 61,000	*$ 4,200
Associated Northern Blocks	2,386	29,500	....
Chaffers	2,450	14,800	*9,300
Golden Horse-Shoe	24,420	186,500	33,000
Golden Ridge	2,758	32,700	14,000
Great Boulder Perseverance	21,146	143,000	35,000
Great Boulder Proprietary	17,473	240,000	127,500
Great Fingall	7,590	69,000	17,500
Hainault	5,506	34,000	1,250
Ivanhoe	20,124	202,000	90,000
Kalgurli	10,760	108,000	45,000
Lake View Consols	†8,145	88,000	2,950
Lake View & Star	15,531	94,000	12,000
Oroya Black Range	4,600	46,000	15,400
Oroya Links	9,020	56,000	8,500
Sons of Gwalia	13,725	133,500	49,000
Sons of Gwalia South	2,399	16,000	5,000
South Kalgurli	9,404	60,000	11,000

*Loss.

†From old dumps by vacuum treatment.

During the month under notice, 11 mines on the 'Golden Mile' spent $105,000 in development work, this being about the average expenditure.

General Mining News

ALASKA

Juneau

Placer discoveries near Uyak, on Kodiak island, have caused a rush for that place, according to recent despatches from Seward.

Prince William Sound

W. A. Dickey, of Landlock bay, recently shipped 175 tons of high-grade copper ore to the Tacoma smelter.

The Fidalgo Copper Co., at Fidalgo bay, is grading for a 900-ft. surface tram.

William J. Morton, of Valdez, has been named receiver for the bankrupt Night Island Con. Copper Company.

The Tanana

Miners and other citizens of Ruby City on November 10 held a 'miners' meeting' to consider the 'high cost of living.' Telegrams from the Commercial company promising an investigation were read. Although no organization was formed 'grub-prices' dropped one-third to one-half immediately after the meeting.

The Owl group of claims on Engineer creek is being opened up by E. A. Williams, one of the principal owners, says a report from Fairbanks.

Pay-ore has been found on Pearl creek, a small tributary of Fish creek, by Henry and James White, states a report from Gilmore.

ARIZONA

Gila County

John D. Ryan, for the Amalgamated Copper Co., offered on November 21 to buy all individual holdings of shareholders in the Live Oak Development Co. for $30 per share. All offers had to be made by December 7. By this arrangement shareholders were enabled to obtain the same price as was paid for the stock purchased from Hayden, Stone & Co. Mr. Ryan obtained an option on 23,050 shares before the general announcement was made November 28 by H. B. Hovland, of the Live Oak company. Payment is to be made in installments, the total sum to be paid within 90 days from November 23.

Maricopa County

(Special Correspondence.)—The Rowley Copper Mines Co. in the near future will erect a 100-hp. boiler, a compressor, and a sinking pump. The equipment has been ordered and is now on the way to the mine. The property is equipped with an 80-hp. boiler, steam hoist, and steam drill. The company has been sinking an inclined shaft on the property, which is 28 miles north of Gila Bend, 8 miles from the Southern Pacific railroad, and is employing 14 men on two shifts. A large amount of ore has been blocked out. The later development has resulted in an increased flow of water. J. O. Goodwin is manager for the company, which has its main office at Kansas City.

Gila Bend, November 29.

CALIFORNIA

Amador County

The Eagle G. M. Co., which was organized recently, is planning to start development in the near future on its holdings, comprising about 600 acres of patented land on the Belluomini ranch, says a report from Jackson. P. L. Cassinelli is president of the company. The company has an option on the property.

When miners in the Keystone mine, near Amador City, brought suit to recover wages for several months, the property was sold at sheriff's sale. W. J. McGee, of San Francisco, bought the deed from the successful bidder, W. G. Snyder. The property sold includes the Keystone mine, the Keystone Gold Quartz mine, the Geneva and Spring Hill mines, the Niagara Quartz Lode mining claim, the East Keystone claim, and all improvements, including a 60-stamp mill and machinery, a compressor, mining tools, and several buildings. The defendants in the miners' suit were the California Con. M. Co., the Amador Keystone M. Co., Jasper McDonald, the Chichizola Estate Co., and I. Lindemann.

Inyo County

The Skidoo M. Co.'s October production amounted to $22,450. Development and operating costs totaled $9124, leaving a net profit of $13,326. During the month the company treated in the mill 1266 tons of its own ore and 229 tons of ore produced by lessees. The bullion production was $17,074. The cyanide production for the first half of the month was $2240, and for the second half, estimated, $2309.

Los Angeles County

Press reports state that the Associated Oil Co. is planning to build a refinery costing about $6,000,000 near Los Angeles. Most of the oil to be refined at the new plant, work on which is to start early in the year, will come from the Lost Hills field, where the company owns about 30,000 acres of oil land. The Standard Oil Co. is rushing the erection of its large refinery at El Segundo.

Henry L. Chase, manager of the Los Angeles branch of the Palmer Union Oil Co., is quoted in the newspapers as stating that the Pacific Mail and Cunard steamship companies are negotiating for millions of barrels of fuel oil from the California fields.

THE KEYSTONE MINE, AMADOR CITY.

Nevada County

To obtain rock for street paving, the trustees of Grass Valley have let a contract for the construction of 'grizzlies' above the dump of the Pennsylvania mine. The smaller bits of waste rock will drop into bins. The bars are two inches apart.

Plumas County

W. P. Hammon recently purchased the Race Track placer claim and other property in the American valley near Quincy.

Sacramento County

Pacific dredge No. 1, belonging to the Guggenheim interests, sank, November 28, near Oroville. It was one of the newest and largest dredges in the Oroville field.

San Bernardino County

The Needles M. & S. Co. has petitioned the War Department for permission to riprap the west bank of the Colorado river to protect the smelter at Needles. It is believed the Santa Fe has joined with the Needles company in the petition, so that a large stretch of country may be relieved from danger from flood. The smelter company in the past year has endeavored to remedy matters by dumping slag along the river bank, but the water has eaten away the bank under the slag piles.

Shasta County

(Special Correspondence.)—While the Mammoth Copper M. Co. of Maine, owning the smelter near Kennett, is endeavoring to avoid a suit such as resulted in closing the Coram smelter, it is making every possible preparation for defense in case suit is brought by the ranchers, according to well-informed mining men. There is a tendency on the part of the farmers and orchardists to blame smelter fume for all their troubles. Many of the small orchardists are comparatively ignorant, and neglect to prune their trees or to thin the crop, as is done by fruit growers in other parts of the State. When the overburdened trees cannot yield heavy crops every successive season, or when the heavily laden boughs break under the weight of the unthinned crop, the orchardist blames his troubles on the smelter. An attack of croup among the children, or the depredations of a black beetle in the orchards alike may arouse the anger of the rancher against the smelter. In addition to improving the bag house so as to eliminate all trace of sulphur dioxide from the emanations from the smelter, the company has practically established a private weather bureau, it is said, and has been taking comprehensive observations of conditions, including air currents, to combat any possible charges by the ranchers. The plant has been operating three furnaces through the summer. The soil in Happy Valley, where the smelter is situated, is only a few feet deep, and the agricultural and horticultural production of the whole county is relatively insignificant compared to the mineral production.

Kennett, December 2.

It is rumored that the First National Copper Co. is planning to operate the Balaklala mine and smelter at Coram. The plan includes the manufacture of sulphuric acid at the plant. T. M. T. Raborg, treasurer of the company, is expected at Coram soon to conduct experiments.

Siskiyou County

The Siskiyou Gold Mining Co. has been organized to develop a quartz property situated near the California-Oregon line, 55 miles south of Grants Pass, Oregon. The incorporators are Andrew Frakes and D. A. Fitzgerald of Grants Pass, and R. H. Bailey of Portland. The property is still a prospect. An adit will be driven to the vein.

Trinity County

(Special Correspondence.)—The Trinity Consolidated Hydraulic M. Co., of which Henry W. Miller is president and W. A. Boland vice-president, has acquired the Union Hill mine and the Hupp mine, together with thirty partly developed and undeveloped mine and water rights near Weaverville. The Rio Plata M. Co. is the owner of two-thirds of the issued stock. The properties acquired consist of the Union Hill mine situated six miles below Weaverville, opened two years ago at a total cost of $250,000 for equipment. It is supplied with a ditch from Grass Valley creek, twelve miles long, which carries 3000 miners' inches of water and a siphon 4000 ft. long carries the water across Trinity river. The siphon is carried on a steel bridge of 236-ft. span. The water-supply lasts for about six months and is delivered to the giants under a head of 460 ft. The mine as equipped will handle about 6000 cu. yd. of gravel per day. The gravel averages 8c. per cubic yard.

The Hupp mine, situated a mile from Weaverville in the Weaverville basin, has been worked for fifty years by the Hupp family and has produced in the neighborhood of $1,500,000. It is completely equipped and supplied with a ditch eight miles long from Weaver Creek and delivers 3000 miners' inches of water under a pressure of 250 ft., for about six months in the year.

The Brown's Ranch mine situated below Weaverville and the Hupp mine in the same basin, have been equipped for work this year and will operate under a pressure of 165 ft. The Hupp mine is equipped for handling about 200,000 cu. yd. of gravel per year, which averages 25c. per cubic yard.

Henry W. Miller, president of the Trinity Consolidated Hydraulic M. Co., is also president of the Rio Plata M. Co. and of the Trinity G. M. & R. Co., which is operating the Headlight mine near Carrville. D. W. Shanks is general manager of the three above named companies. It is the intention of the owners to put in increased equipment which will increase the production of the mines at a small additional cost.

Carrville, November 29.

Tuolumne County

(Special Correspondence.)—Suit has been brought in the Superior Court against the United Mines Corporation by A. C. Maier and Bessie L. Carter. The action comes after a protest made in the United States Land Office at Sacramento against granting a patent to the United States Mines Corporation for the New Albany South quartz claim, in which protest it was alleged that some of the ground sought to be patented belonged to the Triumph claim, held by the plaintiffs. The complaint states that the defendant failed to perform the necessary assessment work upon the New Albany South claim for the year 1898; that in June 1899 the Triumph claim was duly located by A. C. Maier, and that subsequently the latter sold an undivided one-half interest to Bessie L. Carter. It is further alleged that the defendant has entered beneath the surface of the Triumph mine and extracted and converted to its own use gold-bearing ore amounting to more than $25,000. Plaintiffs ask to be declared owners of that part of the Triumph which is overlapped by the New Albany South, for an injunction restraining defendants from extracting any ore therefrom, and also for an order permitting plaintiffs and their surveyors to enter the workings of the New Albany to determine the amount of ore taken from within the Triumph claim by defendant.

The fact that experts are sampling the App mine at Quartz has given rise to the belief that the well known property may soon change hands. It is also reported that the Rawhide is included in the deal supposed to be pending. According to report, the work of sampling the App is being done under the personal direction of Peter Anderson, of Shasta county.

The development at the D. L. Mann copper mine, near Jamestown, is showing fine ore. A dam 26 ft. high has been constructed on Woods creek. Placer claims aggregating 160 acres have been located on the Tuolumne river, three miles below Jacksonville, by E. H. Shackelford, C. M. Auyale, Ruth A. Nelson, W. J. Snook, A. Sumont, William Fay, Mathew Fulman, and Ernest Cowly. The property has been named the Suction Dredge Placer Mine. The owners of the Republican mine may shortly resume operation at the property. It is reported that the company which owns the Dondero gravel mine at Yankee Hill will get a dredge and operate on a large scale.

A shaft being sunk on the Louis Page ranch, at Yankee Hill, has penetrated into a rich gravel deposit, and it is believed that a big mine will be developed. Prospecting operations have been started on the Shine ranch, two miles northwest of Sonora, to determine the value and extent of gravel deposits. The Phoenix Lake M. Co. has levied an assessment of 2c. per share, payable on or before January 1 next.

Some development work is being done at the Sunny South mine, near Tuolumne, which was the object of much litigation recently. The annual meeting of the stockholders of the Springfield Tunnel & Development Co. will be held January 6, 1912, at the company's property at Springfield. One of the purposes of the meeting is to elect directors.

Tuolumne, December 2.

(Special Correspondence.)—It is reported that the famous App mine is about to be sold, there being twelve men at present actively engaged in the work of sampling the property in charge of G. Claus, a French mining engineer. W. A. Nevills is the present owner and manager.

Quartz, November 30.

COLORADO

Boulder County

John R. Wolff and associates of the U. S. Gold Corporation, have acquired the Livingston mine and mill, at Sugar Loaf, by buying a mortgage on the property, which includes four lode-claims and two millsites. After clearing title to the property, according to recent reports from Boulder, the purchasers will turn it over to the corporation.

Clear Creek County

(Special Correspondence.)—A company is being organized to take over the Lebanon and Everett groups of 29 lode mining claims, tunnel-site, and millsite on Republican mountain. It is stated that a 100-ton concentrating plant and compressor plant will be purchased early next spring. B. C. Catren is resident agent. A vein has just been intersected by the Homestake adit on Lincoln mountain that shows a 6-in. streak of smelting ore assaying about 4.30 oz. gold per ton. A. L. Stephens is manager. A shipment of 50 tons of smelting ore is being made from the Clyde B. property. Free gold is visible and a return of $55 to $60 per ton is expected. G. Crumley is manager. Work will be resumed next week on the Ramsdell mine. The Market adit is to be driven ahead to cut the Golden Jack vein. G. W. Teagarden is manager.

Georgetown, December 2.

Edward Skahen has obtained a 99-year lease on the Empire Tunnel property from A. Harley, says a report from Georgetown.

El Paso County

The U. S. R. & R. Co., according to reports from Cripple Creek, has withdrawn from the ore field. It owns the Standard and Philadelphia chlorination plants at Colorado City and the Union mill at Florence. The Golden Cycle M. Co. mill will handle the ore covered by contract. The shutdown was caused by the low tonnage of ore coming from the Cripple Creek district, and when the conditions warrant, the U. S. plants will be reopened, according to a statement by J. D. Hawkins, general manager for the company.

ISABELLA MINE, CRIPPLE CREEK.

Ouray County

The annual report of the Tomboy G. M. Co. shows that the profit for the year ended June 30 was £63,860. The ore treated amounted to 116,222 tons and yielded $6.72 per ton. The net profit on the ore averaged $2.34 per ton. The ore reserve at the end of the fiscal year was estimated at 427,000 tons. The principal matter of interest discussed at the annual meeting, held November 16 in London, was the purchase by the company of the Virginius property last summer from the Revenue company. Arthur Butler, one of the Tomboy directors, in his report stated that the recently acquired property promised "to yield in due course substantial profits."

Teller County (Cripple Creek)

The output from the Cripple Creek district during the month of November was 77,204 tons of ore valued at $1,356,966, against an output in October of 77,717 tons valued at $1,302,704. The table of production, compiled from the reports of the mill managers, as reported in the *Cripple Creek Times*, is as follows:

Plant.	Tons.	Av. value.	Total.
Wild Horse	800	$3.20	$2,560.00
Portland	10,500	21.50	225,750.00
Stratton's Independence.	10,294	2.75	28,308.50
New Portland	11,860	3.05	36,173.00
Smelters	4,000	65.00	260,000.00
Standard Plant	13,050	21.50	280,575.00
Jo Dandy mill.........	900	4.00	3,600.00
Golden Cycle	26,000	20.00	520,000.00
Total	77,204		$1,356,966.50

The Colburn mill, now in operation, will be represented in the December report. The Blue Flag mill will start about January 1, according to current rumor.

At the fourth level of the Lee shaft of the Isabella M. Co., ore assaying as high as 20 oz. silver per ton was discovered in a vertical vein. It is believed, however, that the ore shipped from the vein, which is 6 to 8 ft. wide, will average about 5 oz. per ton.

The Anchoria-Leland mine, on Gold hill, shipped 30 cars of ore in November. The Conundrum mine, Gold hill, shipped 5 cars. Earl Howbert is superintendent of both properties.

The amount of water now flowing from the portal of the Roosevelt drainage adit is 12,000 gal. per minute, as the result of developments Wednesday of last week. Miners working in the south drift on the C. K. & N. vein from the Fuller cross-cut opened a new flow larger than the one opened a month ago. The former flow of 500 gal. per minute which came through the 1000-ft. level of the El Paso shaft has ceased, and it is believed that the water is flowing into the adit through the new water course. In November the main heading was advanced 245 ft., or at the rate of about 8 ft. per day. This feat establishes a new record for this particular undertaking. The flow during November was 8500 gal. per minute.

The Gilpin & Cripple Creek G. M. Co.'s Atlanta claim, on Bull hill, has been sold at sheriff's sale to F. W. Gale, of Colorado Springs, for $37,240. The Maria A. claim, north of the Jo Dandy, on Raven hill, was sold at sheriff's sale to Hildreth Frost for $2750.

MONTANA

Lincoln County

(Special Correspondence.)—The prospecting work so far done on the Libby Creek placer property, recently purchased by W. H. Graham, shows ore assaying $1.50 per cubic yard, the owner states, and bedrock has not yet been reached. The placers are being prospected with a steam drilling-machine, which now has a hole down 37 ft. deep. It is intended to erect a large hydraulic plant on this property, the equipment for which will be taken in over the snow this winter. It is hoped to have the plant in operation by April 1. Mr. Graham has gone to his home in California and, while away, will order the machinery and supplies. He states that when the plant is in operation, it will have a capacity of over 6000 cu. yd. per day.

Libby, December 2.

(Special Correspondence.)—Work on the three-compartment shaft at the Snowshoe mine is going ahead steadily, and 150 ft. of new work will soon be completed, giving a total depth of 617 ft. The vein has widened steadily as depth has been attained and the ore-content has increased in value. Shipments of concentrate are being made regularly to the smelter at East Helena, and E. H. Wilson, consulting engineer, who is operating the property for the Pacific Coast Smelting, Refining & Mining Co., expresses himself as being well satisfied with results.

Libby, November 29.

NEVADA

Elko County

It is rumored that George Wingfield, president of the Goldfield Con. M. Co., has acquired control of the Bluster property, in the Jarbidge district, from Ed. Benane, one of the owners. The price for controlling interest is said to have been about $500,000, or at a rate of $750,000 for the whole property. Mr. Wingfield's Success property, in the Jarbidge district, adjoins the Bluster.

Esmeralda County

(Telegraphic Correspondence.)—The November production of Goldfield Con. M. Co. is estimated at 28,628 tons of ore. The net profit for the month was about $500,000, the gross value of the production being $705,000, and the operating expenses $205,000.

Goldfield, December 6.

Exploration work will be done on the northern part of the Combination Fraction property, near the Mohawk and Combination mines of the Consolidated. For the past eight months before work was suspended last year the company failed to make a profit. The northern part of the claim has not been fully explored.

The Pittsburg Silver Peak M. Co. mill at Blair is treating about 500 tons of ore per day at a cost of $2.64 per ton, according to an interview given by Frank Knox, a director of the company. The net profit from the property is said to be $40,000 to $50,000 per month, and the gross return from the first ten months of the year was $747,000. About 200 men are employed in the mine and mill. The company has a surplus of about $1,400,000 and will pay dividends in the near future, according to Mr. Knox.

The hoist, carpenter and blacksmith shops, engine house, and assay office of the Florence Goldfield M. Co. were destroyed by fire last week, and the shaft timbers are badly burned to a depth of 30 ft. The insurance on the destroyed property is reported as $125,000.

The Goldfield Belmont M. Co. has announced its belief that the orebody recently found in the winze at the 350-ft. level is the rich vein from which it has been shipping at the 300-ft. level.

The Goldfield Vernal M. Co. has stated that in the north workings from the McKane shaft the vein has widened to $2\frac{1}{2}$ ft. and that the ore assays about $40 per ton.

Press accounts state that ore assaying as high as $1000 per ton has been shipped from the Klondike district, a few miles north of Goldfield. James Golden, operating the Original Klondike M. Co. property, is reported to have shipped as much as 300 cars of ore per month, the ore on the average assaying $25 per ton. Other companies are operating in the district.

Ore said to be rich in free gold recently caused a rush to the Wellington district, near Antelope Springs and not far from Jamestown. J. F. Vardaman and L. K. Koontz headed one party. The district is about forty miles north of Goldfield.

HUMBOLDT COUNTY

The Associated M. Co. soon will undertake extensive development on its property in American canyon, say press reports. The company will do most of its work through the Robinson shaft and hopes to develop sufficient water-power for development purposes.

C. M. McCurdy, of Spokane, and Henry Stanislawsky, of Reno, have obtained a six months option on 300 acres of placer ground at the mouth of Rochester canyon from Jones and Jennings, of Fitting, according to a report from Lovelocks.

NYE COUNTY

(Special Correspondence.)—The erection of the MacNamara mill is progressing so rapidly that the management expects to have it in commission early in January. The foundation and roofing is completed and machinery is being placed in position. The favorable weather has facilitated rapid work. The south cross-cut on the 950-ft. level of the North Star has intersected a 3-ft. vein assaying $30 to $60 per ton. The vein lies 10 ft. from the Montana-Tonopah line and appears to be the western extension of the noted Triangle vein. The shaft at the Halifax is down 515 ft. and has entered a calcite-andesite formation. A dam and pump-station have been provided on the 400-ft. level. The south cross-cut from the 500-ft. level of the West End has penetrated the orebody 10 ft. The orebody in the east stope on this level assays about $40 per ton. The west drift is being sent in a southerly direction to follow the fault and recover the vein. Stoping continues on the 400 and 500-ft. levels, and work is being done on the 300-ft. level. The mill is treating 110 tons of ore and tailing per day. It is understood 100 tons of $12.50 ore forms an average daily run, aside from the old tailing. It is rumored that the Tonopah Extension M. Co. may commence the payment of dividends next spring. However, this has not been officially confirmed. The Peak-Steen-Cicala lease on Manhattan Big Four has completed the milling of 1000 tons of ore at the War Eagle plant. The quartz averaged $33 per ton. It was extracted between the 300 and 400-ft. levels. The vein is said to be 18 ft. wide. Development is under way near the 400-ft. point. The pumps are easily handling the water. About 65 lessees are operating at Manhattan, and the custom plants continue unable to handle the large quantities of ore produced. This feature handicaps operation, but development is being done on practically all the prominent holdings.

Tonopah, December 1.

The Tonopah Belmont Dev. Co. has declared a dividend of 25c. per share, payable January 1. This will mean the distribution of $375,000, and will bring the total amount paid by the company in dividends to $2,468,000, of which $1,350,000 will have been distributed since the beginning of this year.

The Tonopah Extension M. Co. is now free from debt and has a cash balance, according to a recent statement by J. G. Kirchen, general manager for the company.

The ore-shipments for the Tonopah district last week were as follows: Tonopah M. Co., 3500 tons; Belmont, 2355 tons; Montana-Tonopah, 915 tons; Tonopah Extension, 1015 tons; West End, 500 tons of ore and 325 tons of tailing; Midway, 50 tons of ore; total, 8335 tons, valued at $298,375.

STOREY COUNTY

H. L. Slosson, Jr., was elected president of the Mexican M. Co., in San Francisco, December 5. At the regular meeting of the stockholders Mr. Slosson, John Landers, and W. C. Ralston were substituted on the board for B. F. Shaw, William Bannon, and A. F. Coffin. G. E. Arrowsmith and Herman Zadig were retained. C. D. Olney was chosen secretary, Whitman Symmes manager and resident agent for Nevada, and John Landers vice-president, at the executive session of the directors. The new directorate will start the most active development the Comstock lode has seen. It is charged that Mr. Zadig for a number of years has received a revenue of $200 per month from wrongful commissions on mine supplies, particularly powder, and $75 per month voted by himself for auditing the books of the company. Mr. Zadig maintained at the meeting that he did not consider he had done anything wrong. Of the 201,600 shares of stock, 199,000 were represented at the meeting.

The Ophir mine last week produced 426 tons of ore valued at $18,524. Mining was resumed on one shift in the Union and Mexican mines, the other two shifts being employed on the repairs to the Union shaft. The joint winze was sunk 10 ft. through porphyry and is down to a point 672 ft. below the 2000-ft. station. The Con. Virginia company continued its usual repairs. The drift on the 2550-ft. level was advanced 17 ft. through low-grade quartz. In the C. & C. shaft, after a week of pumping, the water stood 296 ft. below the measuring point at the 2350-ft. station. The roof of the raise in the Julia Con. is in vein matter. No changes were reported at Brunswick No. 1 shaft. Work in the Overman was confined to the 1200-ft. level. At the Crown Point 155 cars of ore averaging $4.78 per ton, were drawn off. The Yellow Jacket mill ran all week on dump ore, handling 1127 tons. The joint incline at the Belcher is now retimbered for 70 ft., or to the water-line.

WHITE PINE COUNTY

Exploration work soon will be done on the Butte & Ely Copper Co. property as the result of a recent visit to the place by prominent stockholders, according to rumors in the newspapers. The Giroux Con. retains a controlling interest in the property, but it is reported that there is a tacit agreement that development work to discover new orebodies shall be undertaken.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Ernestine M. Co.'s bullion product for the second ten-day period of November amounted to 8500 oz. of gold and silver, and 10,500 lb. of dry concentrate was shipped. The past week's ore treatment was 685 tons. The erecting engineer for the De La Vergne company is on the ground assembling the oil engines. It is thought the new power plant will be ready for operation the first of the year.

One carload of parts for the De La Vergne engine installation arrived in Silver City last week and is now being taken to the Socorro mines by team. Several more cars of machinery have been shipped from factory for the new power plant. The mill continues its regular shipments of bullion and concentrate.

Mogollon, December 1.

OREGON

Josephine County

The Greenback mill soon will have 20 of the 40 stamps dropping. Some new machinery has been ordered and is on the way there, says a report from Grants Pass. New ore reserves are being mined and the property will be put again on a paying basis, according to an announcement by F. M. Leland, who is acting in an advisory capacity to the owners, Robertson & Son.

The Cougar Con. Mines, with headquarters at Galice, will equip the Barr placer mine, consisting of 16 claims, with an electric-light plant, sawmill, new flume, grizzlies, and 15-in. pipe. L. H. Medford is manager and Ned Heath superintendent for the company.

UTAH

Juab County

The Grand Central M. Co. has declared a dividend of 5c. per share, payable December 20, which will require the disbursement of $25,000 on the 500,000 shares issued. The company is capitalized at $600,000, with shares $1 at par. There is in the treasury 100,000 shares.

Newspaper reports assert that the Beck adit will cause a big revival in mining in the Tintic district. The new orebody recently found in the development trends to the south, and not to the east or southeast, as was at first feared. The fact gives rise to the belief that a second 'Colorado channel' has been discovered.

In the Yankee Con. property, Tintic district, the showing of ore in the 1900-ft. level is encouraging. Development is being done on the 1800, 1900, and 2000-ft. levels. The company is shipping an average of 12 cars of low-grade silicious ore per week, according to a statement by Lew Merriman, superintendent of the property.

The annual report of the Iron Blossom Con. M. Co., made at the meeting in Provo, December 2, shows a cash balance on hand of $138,000. During the year 55,000 tons of ore was shipped, and 6000 ft. of development work was done. Dividends paid during the year amounted to $29,000.

Salt Lake County

To avoid danger to life and property from snowslides what ordinarily would be the surface plant of the Utah M. Coalition Co. has been placed beneath the surface, and the former company village has disappeared. Only the ore-bins and the dump remain in the path of possible slides. One of the cross-cuts from the adit, near the portal, has been enlarged and utilized for the boarding-house and bunk-house. This solution of the problem presented by snowslides is said to be unique in the West.

Summit County

Assessment work is being done on the Old Glory group of claims in the Big Cottonwood district. Application for patent will be made early in the new year, and extensive development is planned.

Work has been started on what will be known as the Uintah-Treasure Hill cross-cut. This will connect the 260-ft. level of the Treasure Hill mine and the 900-ft. level of the Silver King Coalition mine. The cross-cut will be about 900 ft. long, and is designed to give an outlet for the waste of the Silver King Coalition without hoisting to the surface.

The Miller & Beggs company is building a tailing mill at Park City. The plant will be equipped with Wilfley tables and Macquisten tubes, and will have a capacity of about 40 tons per day. The concentrate to be treated, it is reported, averages about 52% zinc.

WASHINGTON

Spokane County

(Special Correspondence.)—A Spokane local of the American Institute of Mining Engineers has been formed with R. S. McCaffrey, of Moscow, Idaho, as chairman; G. A. Collins, of Spokane, vice-chairman, and L. K. Armstrong, of Spokane, secretary-treasurer. There are nearly 100 members in the Spokane local, which embraces eastern Washington, northern Idaho, northeastern Oregon, extreme northwestern Montana, and southern British Columbia east of the Cascade mountains. The following named papers were read: 'North Washington Power & Reduction Co.'s Cyanide Mill at Republic, Washington,' by H. W. Newton; 'Geology of the Silver Bell District, Arizona,' by C. A. Stewart. Four regular meetings will be held each year, with such intermediary meetings as may be decided upon by the executive committee, which is composed of the officers and two other members, who are F. A. Thompson, Pullman, Washington, and James F. McCarthy, Wallace, Idaho.

Spokane, December 1.

CANADA

British Columbia

Frederic Keffer, engineer for the British Columbia Copper Co., has confirmed the report of the bonding of that corporation of 60 claims in Voight's camp in the Similkameen mountains. The deal includes 2000 acres of land, timbered and grazing, which would supply a smelter site, should one be required.

Number One mine, a silver-lead property at Ainsworth, has been taken over on a lease and bond by the Consolidated Mining & Smelting Co. of Trail.

Jay P. Graves, of Spokane, general manager for the Granby company, predicts that 1912 will be better than this year, when the profits were $217,416. The mines at Phoenix produced and shipped 940,565 tons of ore this year, against 1,175,543 tons last year for the same period.

Negotiations have been closed by which 'Bob' Mabry, of Spokane, acquires three properties in the Ymir district. The best known is the Yankee Girl, for which he paid $100,000 to John Frazer, acting for the creditors. He paid $40,000 for the Bi-Metallic and the Lost Cabin properties.

Payne mine near Sandon, which paid $1,438,000 in dividends during its corporate existence under Canadian ownership, has been acquired by Robert E. Strahorn, of Spokane, vice-president of the Oregon-Washington Railroad & Navigation Co., and his associates, and will be incorporated in British Columbia as the Payne Mines, Ltd., with a capital of $1,500,000, of which $250,000 is to be in 6% preference debentures and the rest in common stock.

Ontario

At the Davidson mine of the Crown Chartered Co. drifts are being driven in both directions from the main shaft on pay ore-shoots. Free gold is visible in the ore from both faces. Developments at the 100-ft. level have been so favorable that the management has decided to immediately increase the capacity of the mining plant. Accommodations are being provided for an additional force of fifty men.

MEXICO

Chihuahua

The Dolores M. Co., about twenty miles from Madera, last week shipped 68 bars of gold and silver bullion, valued at $121,000, to the Banco de Sonora branch at Chihuahua.

Jalisco

The Mololoa mine, owned by the Mololoa M. Co., in the Hostotipaquillo district, is yielding unusually high-grade ore, according to reports from El Paso, Texas. A reduction plant will be built this season. The power will be supplied from the El Favor station of the Chapala hydro-electric company.

Mexico

Rich ore has been found in the Riveria mine, near Nacozari, in the adit, 600 ft. from the portal. G. J. Cole is manager of the mine.

It is rumored that a mill may be built at the Monte Visto mine, near El Tigre. The mine contains low-grade gold and silver ore.

Book Reviews

Any of the books noticed in these columns are for sale by or can be procured from, the Mining and Scientific Press

The Mineral Industry of Rhodesia. By J. P. Johnson. Pp. 90. Interleaved. Longmans, Green & Co., 1911. For sale by the *Mining and Scientific Press*. Price $3.

This little volume, by a well known writer upon African mineral resources, deals in a comprehensive way with the mineral resources of Rhodesia, and is conveniently interleaved with blank pages for the addition of notes regarding future discoveries and development.

Graphical Solution of Fault Problems. By C. F. Tolman, Jr. Pp. 43. Ill. The *Mining and Scientific Press*, San Francisco, 1911. Price $1.

The mining engineer, when called upon to map a faulted group of strata and to correctly interpret his data, is apt to find himself somewhat at a loss, since his instruction in descriptive geometry was not directed in this direction and, in addition, is perhaps largely forgotten. Mr. Tolman's little volume furnishes a ready and convenient means of making good any such deficiency and is likely to prove of much service.

Design and Construction of Mill Buildings. By H. G. Tyrrell. Pp. 490. Ill. Myron C. Clark Pub. Co., 1911. For sale by the *Mining and Scientific Press*. Price $4.

This volume deals with mill construction in the sense of the term employed by a manufacturer and only covers metallurgical mills in the larger treatment of the subject. In this it is unusually good, and is likely to become a standard work upon this topic. It will be especially serviceable to mining engineers and metallurgists, since it is written in such a way as to be easily intelligible to those who are not professional builders and architects. Such persons will be grateful for a compact volume concisely but intelligently covering all the phases of mill building construction.

Dredges and Dredging. By Charles Prelini. Pp. 279. Ill. D. Van Nostrand Co., 1911. For sale by the *Mining and Scientific Press*. Price $3.

To the civil engineer this volume will be of much interest and service, as the discussion of the various types of river and harbor dredges appears to be unusually full and complete. But to the dredging for metals only one chapter, of 16 pages, has been devoted, the author evidently drawing his information entirely from technical journals. And as the most recent information given regarding gold dredges is taken from an article which appeared in the *Mining and Scientific Press* of April 17, 1909, it is not likely that those engaged in the gold dredging industry will find much profit in its perusal.

Mining Without Timber. By R. B. Brinsmade. Pp. 307. Ill. McGraw-Hill Book Co., 1911. For sale by the *Mining and Scientific Press*. Price $3.

With the growing divergence between the increasing cost of timber and the necessarily decreasing costs of mining, the development of methods of mining which do not involve the use of timber has been greatly stimulated in the past decade. Mr. Brinsmade's book is therefore timely as well as useful, discussing, as it does, not only open-cut systems, but various methods of stoping with a minimum of timber, the different caving and slicing systems and the mining of coal seams. These are discussed by the use of examples of each of the methods, some 60 in all being cited and described in detail. Treatises descriptive of mining methods too often are lacking in practicability, and this volume will be correspondingly useful, therefore. The author's good judgment is to be commended in the omission of topics extraneous to his subject and the omission of foreign examples that appear likely to be of little service in American practice. It would have been best to have rigidly adhered to this intention, the first three chapters, on explosives, the principles of blasting, and the use of compressed air underground are unnecessary to the logical development of the main topic, and the final chapter, on the principles of mine valuation, is decidedly out of place. More careful proof reading would have eliminated such errors as "Goyebic" (Gogebic) (p. xiii), "hangwall" (p. 207) and the statement, on page 208, that raises "cost $4 to $5 per ft." But such things the reader is likely to overlook in the great interest of the subject matter.

Metallurgy. By Herbert Lang. Part I. Introductory. Pp. 255. Ill. McGraw Hill Book Co., 1911. For sale by the *Mining and Scientific Press*. Price $3.

This volume, the first of a series of three, contains so much that is admirable, as well as that which is not, that it is difficult to review it briefly. The author's long and wide experience as a metallurgist, admirably qualifies him for the task of discussing the subject from a general standpoint and, in particular, his treatment of the general question of smelter fume, in the last two chapters, is so admirable as to alone make the book worth while. Nevertheless, with much of the remainder of the volume we cannot find ourselves in agreement, and this disagreement is radical and fundamental. Metallurgy is stated, in the introductory chapter, to "overlap applied chemistry in some directions," though it is obvious, upon a moment's reflection, that metallurgy is only a single department of the larger subject of applied chemistry and, as commonly used, does not even cover all of metallurgy proper, but only the metallurgy of the precious metals and those used as materials of construction. Nor is it true, as the author contends, that the metallurgic methods applied to the individual metals are so closely similar that they can best be treated together. The smelting of iron ores (always oxides) and copper ores (generally sulphides) in furnaces of radically different design and capacity differ so markedly that they cannot be treated adequately except separately, though, as the author contends, the study of the metallurgy of an individual metal should be prefaced by a general study of metallurgical processes, in order that an adequate grasp of the underlying principles may be obtained. The author's method of classification of metallurgic processes is extremely helpful, but might be carried out with more care; for example, on page 95, the division 'Processes acting by differences in density' (density being here used in the sense of specific gravity) is immediately followed by 'Acting by amalgamation with mercury,' though plate amalgamation is simply a special case of difference in specific gravity, while the patio and related processes chiefly depend upon chemical action, which forms the next subdivision. And in the subsequent analysis of processes it would have been well to have indicated in some manner the relative importance of the processes listed, so that the little used Rozan process would not take precedence over the Parke's [*sic*] process. In spite of the author's scorn for foreign texts and publications, he has evidently been influenced by the older texts, such as Schnabel's, in the division of his subject and thus led into a lack of balance, such as devoting, on pages 98 and 99, to the treatment of matte twice the space accorded to pig iron. It is unfortunate that the author has divided his treatise into three volumes; the *raison d'etre* of a general metallurgy is the presentation in one volume of a general view of the whole subject, and once the number of volumes is multiplied the reader justly feels that a number of texts, by different authors, dealing with various phases of the subject, is likely to better meet his needs. That American textbooks and technical journals are ample to meet the needs of the well-read metallurgist is far from the truth is exhibited by the fact that there does not exist in America a metallurgical journal to be compared with *Metallurgie*, nor are metallurgists generally likely to agree that the half-dozen authors referred to in the introduction constitute an adequate metallurgical library. It is easier to criticise than commend, and there is much in this volume that is excellent, so much that metallurgists will wish to judge for themselves. T. T. R.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

POPE YEATMAN was at Ely recently.

B. KIMBALL has returned from Mexico.

EDWARD L. DUFOURCQ is at the Fairmont.

J. MALCOLM MACLAREN is in San Francisco.

W. G. ANDERSON has returned from Mexico.

GEORGE KISLINGBURY is in San Francisco from Los Angeles.

R. C. SPECHT is examining properties in Trinity county, California.

ARTHUR K. ADAMS is with the General Land Office, at Los Angeles.

MORTON WEBBER sailed for England on the *Lusitania* on November 29.

FRED L. MORRIS has gone to Mexico and will stay until after Christmas.

C. B. LAKENAN was in San Francisco early in the week and returned to Ely.

W. M. HENDERSON SCOTT is at the Wettlaufer mine, Silver Centre, Ontario, Canada.

ALGERNON DEL MAR was in San Francisco and has gone to South Pasadena for the holidays.

N. L. BURNER, superintendent of the Evening Star mine, Old Diggings, was in San Francisco this week.

E. H. SIMONDS recently returned to San Francisco from Inyo county and has left for Calaveras county on professional business.

H. W. EDMONDSON has returned to Los Angeles for an examination of the Camuchin properties in the Arteaga district, Chihuahua, Mexico.

SUMNER S. SMITH is now at Cordova, Alaska. He expects to leave Cordova for Fairbanks over the winter trail about the middle of January.

D. W. SHANKS, general manager for the Trinity Gold Mining & Milling Co., has returned to Los Angeles from an extended trip in northern California.

C. E. BODYSTON, formerly mining engineer for the Consolidated Mining Co., Jalisco, has been appointed manager for the Cubana Consolidated Copper Co. at Arizpe, Sonora.

NEWTON H. WINCHELL addressed the Geological Club of the University of Minnesota on November 23, on the work of the Minnesota Geological and Natural History Survey.

THOMAS K. CODE, general manager for the Mayflower Bullfrog Con. M. Co. and the Mayflower Leasing Co., has accepted the appointment of consulting engineer for the West Extension M. Co. at Rhyolite, Nevada.

Obituary

GEORGE A. TREADWELL, who was well known in California, died in New York City on November 12. Mr. Treadwell was at one time engaged in mining at Nevada City and later was prominently associated with W. A. Clark in the development of copper mines in Arizona and elsewhere; an association which was later marred by protracted litigation. A man of wide culture and experience and an entertaining companion, he leaves many friends.

JAMES DRUMMOND MINOR, one of California's pioneer miners, died at Nashville, Eldorado county, on December 4, at the age of 83. He arrived in San Francisco by way of the Isthmus in the spring of 1850 and engaged in mining operations in Eldorado, Placer, and Plumas counties. He left California in the sixties, and was for a number of years engaged in mining operations in Unionville, Nevada, and Bodie, California. He was Secretary of State of Nevada from 1868 to 1876.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS

CONTRIBUTORY NEGLIGENCE

A miner entering a cage for the purpose of ascending the shaft under the direction of the foreman of the mine was not guilty of contributory negligence where, in attempting to ring the bell to signal the hoist, he found the bell rope wet and the bell hard to ring, and in the attempt he slipped, struck his elbow and fainted, and in falling caught his leg between the wall and the cage, resulting in the injury complained of.

Osterholm *v.* Boston & Montana Consolidated Copper & Silver Mining Co., (Montana) 107 Pacific, 499.

EVIDENCE--RECORDS OF INSPECTION

The statutes of Kentucky require the inspector of mines to keep a record of all inspections made by him and provides also that a certified copy and such inspection shall be admissible in evidence in any court. In an action between a lessor and a lessee involving the condition of a certain mine which had been inspected by the inspector of mines it was held that his reports were official public documents and a proper certified copy thereof was properly admitted in evidence.

Henderson Mining & Manufacturing Co. *v.* Nicholson, (Ky.) 126 Southwestern, 139. March 1910.

OPTION ON MINING CLAIMS

A contract to convey mining claims for a specified sum in cash and other payments to be made in one or two years, with a stipulation that the purchaser might take possession of the claims and develop them, and providing that the purchaser should abide by the terms of the agreement and in default of any of the payments, to surrender such claims to the owner and forfeit all moneys paid and expended, is nothing more than an option, and the purchaser is left to his election within the life of the agreement to purchase or a forfeiture of all sums paid or expended. But the purchaser entering under such an option and employing laborers to perform the work, can establish no indebtedness in favor of the miners against the owners, and no lien attaches to his interest in the property, as such work is not performed by virtue of any employment from the owner, and the person holding such option is neither a vendee nor an agent of the owner. In such an option, time is said to be the essence of the contract and a failure of the original purchaser or his assignee to pay the balance due on the specified debts relieves the original owner of any obligation to convey under the option agreement and all rights are forfeited.

Harper *v.* Independence Development Co., (Utah) 108 Pacific, 701.

ASSUMPTION OF RISK

A person entering voluntarily into a contract of service assumes all the risks and hazards ordinarily incident to the employment and such as are liable to arise from defects which are patent and obvious to a person of his experience and understanding, and he assumes all the ordinary risks of the employment which are known to him and which would have been known with the exercise of ordinary care; it is his duty to exercise care and diligence and observe and become cognizant of obvious defects in the machinery and the work place, and he is charged with the knowledge of such defects which would have been known to a person of reasonable care and prudence. But notwithstanding this rule, an employee does not ordinarily assume risks arising out of the negligence of his employer. This rule was applied in an action against a mine company for the death of a miner acting in the capacity of a shot-firer resulting from injuries caused by smoke, fumes, foul air, and poisonous gases by a reversal of a fan on account of its not having been suitably adjusted with reasonably necessary appliances for the purpose for which it was installed, and where it was shown that the omitted appliances were reasonably necessary in its operation for such purposes, and the omission of such suitably adjusted fan with such additional appliances was held to be the proximate cause of the injury.

Coalgate Co. *v.* Hurst, (Oklahoma) 107 Pacific, 657.

Company Reports

THE SANTA GERTRUDIS CO., LTD.

This company, formed by the Camp Bird Limited in 1909, with capital of 1,225,000 shares of £1 each, increased in January 1911 to 1,500,000 shares, of which 1,368,000 have been issued, is the holding company, the Compañia de Santa Gertrudis, S. A., being the operating company. This has a capital of ₱250,000, and the holding company has advanced it £1,019,000 for the purchase of mines and machinery and for construction, equipment, and development work. The milling company is the Compañia Beneficiadora de Pachuca, S. A., with a capital of ₱500,000, and £92,115 has been advanced this company. The report of the holding company for the year ended June 30 shows that the past eighteen months have been occupied in preparing the mine and mill for the increased scale of operations. Many improvements have been made in the shafts and their equipments, and in particular the old San Guillermo shaft has been repaired and made the main hoisting shaft, with a capacity of 1000 tons per day. An advantageous contract has been made with the Mexican Light & Power Co. for the supply of electric power. The new mill was ready for work on June 14. It consists of 60 stamps of 1550 lb. each, 10 tube-mills, 18 Pachuca vats, Merrill slime-filters, Dorr thickeners and classifiers. W. J. Cox, the consulting engineer, and Hugh Rose, the manager, report that the development has greatly added to the ore reserve, the figures now being 630,000 tons of proved ore estimated to yield a profit of $4,610,000, and 250,000 tons of probable ore estimated to yield a profit of $3,565,000, or a total of $8,175,000.

CAMP BIRD, LTD.

This company has an authorized capital of 1,350,000 shares of £1 each, of which 1,100,051 have been issued. In addition there is £500,000 of 6% debenture stock, and was floated in London in 1900 by F. W. Baker and J. H. Hammond to acquire the Camp Bird mine from T. F. Walsh. The mine is now nearing exhaustion, and the report for the year ended April 30 shows that the amount of ore discovered during the year was very small, the ore reserve standing on April 30 at 38,415 tons, as compared with 83,900 tons the year before, 79,186 tons having been extracted in the meantime and sent to the mill. The yield was $1,685,979 in gold, or $22.89 per ton, silver worth $71,435, copper worth $8408, and lead worth $46,748, a total of $1,812,571. The recovery of the gold content was just under 95%. Of the total extraction of metals, 64.32% was obtained by amalgamation, 28.81% in the concentrate, and 6.87% by cyanidation. The concentrate was sold to the American Smelting & Refining Co. The total income at the mine during the year was £372,696, or £4 14s. 1d. per ton, and the expenses £153,262, or £1 18s. 8d. per ton, leaving a profit to be carried forward to profit and loss account of £219,434, or £2 15s. 5d. per ton. The accounts are credited also with £83,691, the par value of vendors' commission shares in Santa Gertrudis, and are debited with £30,000 interest on debentures and £15,248 income tax. The dividends paid during the year have amounted to £220,002, being at the rate of 20%. The total dividends distributed to date have been £1,505,002. Since the close of the company's financial year, the debentures have been retired and preference shares substituted in their place. This company holds an interest of £1,132,096 in the Santa Gertrudis Co., Ltd.

THE Bunker Hill & Sullivan M. & C. Co. paid dividend No. 171 of $65,400 on Monday, December 4. This makes the total amount of dividends paid $13,159,650.

Commercial Paragraphs

O. D. Gogue has been appointed vice-president and treasurer of the Goulds Manufacturing Co., of Illinois.

The Oliver Continuous Filter Co. reports that in the last few months it has installed the following filters in Nevada, and states that over 90% of the filters used in the State of Nevada are Olivers: Nevada Hills Mining Co., Nevada Wonder Mining Co., Mexican Gold & Silver Mining Co., Rawhide Queen Mines Co., and Farmers Mining Company.

The General Electric Co. reports having sold mining locomotives as follows: One locomotive to Asker Coal Mining Co., for Dorothy, Kentucky; one to Ben Franklin Coal Co., for Braeburn, Pennsylvania; one to Inland Steel Co., for Crosby, Minnesota; and one gathering locomotive to Davis Colliery Co., for Elkins Colliery Co., Bower, West Virginia.

The Jeffrey Manufacturing Co. of Columbus, Ohio, has recently opened another branch office at 1201 American Bank building, Seattle, Washington, to handle its business in the Northwest. Percy E. Wright is manager. The Jeffrey Manufacturing Co. is maintaining 13 branch offices in the United States, as well as nearly 100 agencies in the leading commercial centres all over the world.

The Hardinge Conical Mill Co., of New York, is building several 8-ft. pebble mills for the new sections of the Miami Copper Co.'s plant. These mills are used to grind the same material which heretofore has been fed to Chilean mills. The Hardinge company is also building additional mills for the Federal Mining & Smelting Co., and has also received an order from the Bunker Hill & Sullivan M. & C. Co., based upon the latters observation of the work done at the former company's plant.

Among recent installations of Foster superheaters reported by the Power Specialty Co. are the following: New York, New Haven & Hartford railroad, at Cos Cob and Bridgeport plants; Delaware, Lackawanna & Western railroad, at Loomis colliery; International Harvester Co., at Plano and Weber plants; Associated Pipe Lines Co.; Haskell-Barker Car Co.; J. R. Nutt plant, Fort Worth, Texas; Clark Thread Co., Indiana & Michigan Traction Co.; Wilmington & Philadelphia Traction Co.; Penn Central Light & Power Co.; and Citizens Light, Heat & Power Co., Montgomery, Alabama.

LAND has sold in New York recently at the rate of $870 per square foot. The Wyoming 'rancher' can reflect that if his great great grandfather had staked his homestead at what is now Thirty-fourth street and Broadway it would be worth $6,063,552,000.

PEACE in Mexico will not be disturbed through American coöperation, was the tone of a recent message to Congress by Mr. W. H. Taft. Prevention is better than cure, and the firm stand the Administration has taken in this matter is regarded with favor on both sides of the Rio Grande.

DELHI was truly a city of Oriental splendor upon the occasion of the crowning of George V as Emperor of India on Tuesday of this week. The coming of the King to the ancient city to be crowned should strengthen Anglo-Indian friendship, no less than his generous gifts to the cause of popular education in India.

TRULY a curious gathering to advance the cause of peace was the one in Carnegie Hall, New York City, on Tuesday evening, which ended in a call for the police reserve. The eminent gentlemen who were speakers of the evening were doubtless surprised to learn that the citizens of the metropolis are so belligerently disposed.

UNWARRANTED interference in diplomatic affairs is seen in the action of the National and State legislative assemblies in passing resolutions calling for the abrogation of the treaty between the United States and Russia because of the difficulties regarding the issuance of passports. Diplomacy is not a matter of public debate, and the efforts of legislators to engage in it are likely to produce results similar to those of the traditional bull in the china shop.

POTASH investigations by the United States Geological Survey are beginning to bear fruit, and the alunite deposits, recently discovered near Marysvale, Utah, show much promise as a source of potassium salts. Though not large enough to materially affect the importation of potash salts, the discovery is most encouraging, nevertheless. The use of fertilizers, in which potassium salts are essential constituents, is constantly growing, and it is interesting to note, in passing, that a bank in Illinois has established a loan fund, free of interest, to enable the farmers of that district to invest more freely in fertilizers and to raise correspondingly larger crops.

CRIPPLE CREEK is one of the most interesting of mining districts, and of its many valuable mines, Stratton's Independence is easily first in general interest. Much that is untrustworthy has appeared concerning this greatly discussed mine, and we are fortunate, therefore, to be able to present this week an authoritative account by Mr. T. A. Rickard of the development of the property, with which he was prominently identified. It is pleasant to record also that an ore-shoot has recently been discovered upon the 200-foot level and has been proved to persist to the surface, with a reported gold content of 2 ounces per ton, while the drainage afforded by the deep-drainage adit is lowering the water in the deeper workings so rapidly as to permit exploration for additional ore-shoots in depth.

Japan and the Mining Engineers

In this issue we print the third and concluding letter of a series describing in outline the trip made by members of the American Institute of Mining Engineers to Japan. More detailed descriptions of several of the properties visited will follow. We take this occasion, however, for a word of thanks to the Japanese hosts, on behalf of our representative and the other engineers of the party. Hospitality would seem to be the chief pleasure of the Japanese, if the experience of the American visitors affords any test. Japanese courtesies began before the party left San Francisco, the local committee sending Mr. Reiji Kanda to that city to meet and escort the Americans to his home country. A better choice could not have been made, since to his native ability Mr. Kanda has added an excellent knowledge of English and a large acquaintance among foreign mining men. Both on the *Manchuria* going over and throughout the journey in Japan, he laid the Americans under many obligations for his unfailing courtesy and thoughtfulness. The visiting party was the largest, but one, of any group of Americans that had traveled through the Empire, and the mining men of Japan regarded it as especially important. The local members of the American Institute, the Mining Institute of Japan, and the Mine Owners Association, joined in the formation of a general committee which worked indefatigably for the success of the excursion and achieved an eminent success. The chairman was Baron Shibusawa, who has, among other interests, large holdings in mines. Viscount Kaneko, well remembered in America in connection with negotiations at the time of the Japanese-Russian war, was chairman of the banquet committee. The other members of the general committee were Messrs. Takuma Dan, Rentaro Hotta, Reiji Kanda, Keisuke Kato, Benzo Katsura, Rokusaburo Kondo, Masayuki Otagawa, Kingo Nambu, Kageyoshi Noro, Wataru Watanabe, and Shigema Yamanouchi. A number of these men are already well known in America, and of the others many pages might be written without exhausting the record of their good work. In addition, local committees had been organized wherever the party was to stop, and corporations, cities, and provinces vied with each other in entertainments and giving of souvenirs. To an American, with whom gift-giving is much less common than among Japanese, there was a pleasant embarrassment in receiving a pair of gold cuff-buttons or a beautiful necklace for his wife, as a souvenir of a little dinner that was quite charming enough in itself. It is an old rule, however, that it is possible to get used to anything, and this applies even to the constant receipt of presents. Differences in custom produced less embarrassment than might have been anticipated. It is an open secret that the Japanese committee was aghast at the announcement of the large number of women who were to be in the party. There was, indeed, some question among the Americans as to the wisdom of this feature. The women, however, wanted to go, and of course they did so. As a result the Japanese made special efforts to induce their own wives to take part in the entertainment, and it is whispered that the latter, at least, greatly enjoyed the relative novelty. At any rate, both Americans and Japanese became much better acquainted and parted with much juster estimates of each other. A result of the social features of the excursion was the formation of many personal friendships and, on the American side, a greatly heightened respect, not only for the Japanese, but for their ways. Japanese have the Oriental habit of speaking deprecatingly of anything belonging to themselves and in high eulogy of that which belongs to another. It was amusing to see some of the Americans who had taken this too seriously, gradually waken to the real facts. The Japanese have, we are persuaded, a real and deep-seated gratitude to individual Americans for professional courtesies, and also to the American nation for the generally friendly attitude that it has occupied in relation to the Empire. They fully realize the effectiveness of American and European methods in education and industry. At the same time, they have a deep-rooted faith in their own resources, powers, and civilization; a faith born from the maintenance of three centuries of peace quite as much as from 2500 years of freedom from invasion, and the waging of two successful modern wars. When the Westerners broke into Japan in 1853, there was already existing a complex and cultured civilization. Japan, it is true, started then to go to school and began in the primary class, but that was nearly a half century ago, and, furthermore, Japan, while unacquainted with Western learning, was not unlearned. It was more as though graduates of early American colleges severely trained in Greek and Latin, had taken to engineering. They would have needed to begin with the elements, but would not have brought either ignorance or stupidity to the task. No visitor can go through room after room of the Nijo palace at Kyoto, built in 1603, and reflect on the state of contemporary art and architecture in America and Europe at that time, without mentally lifting his hat to native Japanese culture. Neither can any observing miner or metallurgist go through the mines, mills, and smelters of Japan without the feeling that the Japanese engineers may have learned lessons abroad, but have built well on the foundation thus laid and are now drawing heavily on native ability and inventiveness.

It is too much to expect that the various races and nations will give up their differences and become alike. If they did, life would become unbearably monotonous. Purposeless friction, however, results always in loss. Failing agreement, the best thing is understanding, and this is promoted by acquaintance. Too often nations know each other only through contact with traders; and salesmen form an important but only one part in the national economy of any people. Educational excursions are a well recognized pedagogical device, and, while mining engineers travel much and are possibly as cosmopolitan as the members of any profession, such excursions as the one just completed are stimulating and helpful both to host and guest. There has been criticism of the Institute that it was becoming too much of a publishing house with an excursion-bureau annex. While there is point to the criticism, journeys that bring together the members of the Institute and their families promote the solidarity of the profession in geometrical proportion to the number taking part. America and Japan, historically friendly nations, have seemed recently to be drifting apart. Hypercriticism has too often replaced the old friendly comment of the one on the other. This, we believe, does not reflect the real sentiments of the bulk of the citizens of either country. We return profoundly convinced that Japan wants no war that can be avoided, and will approach any international question with only the same desire for fair play and disposition to insist, as would any other self-respecting and efficient people. Japan's face, however, is toward the conquests of peace, and in her progress toward that goal all members of the recent party of visitors will gladly join in the wish expressed by the students of the Imperial University of Tokyo on the occasion of the granting of the national constitution—*Banzai! Banzai! Banbanzai!*

Two Famous Mines—I

By T. A. Rickard

The annual meetings of the shareholders in Stratton's Independence Ltd. and Camp Bird Ltd have recently been held in London, and the reading of the reports prompts me to revert to the story of these two famous mines in Colorado. The discovery that made W. S. Stratton a millionaire was the result of the desultory prospecting of a carpenter. His previous efforts in the San Juan region of Colorado had not been successful, but Stratton was a resident of Colorado Springs and therefore was near Cripple Creek when the first discoveries were announced in 1891. He was among the first to go thither. After trying several places, he found gold in the surface debris on the south slope of Battle mountain. But his pannings at first led to nothing, because he did not test the big outcrop of mineralized granite that was the one conspicuous feature of the hillside. Finally, in desperation, he broke a piece of the granite and took it with him to Colorado Springs. It assayed 19 ounces of gold per ton! That was on July 3, 1891. He returned next day and located the Independence and the Fourth of July claims. We can all write last year's almanac, but it is worthy of remark that the Independence was the only vein in the Cripple Creek district that had an outcrop, and it was so conspicuous that any experienced prospector would, it might be supposed, be quick to notice it and appreciate its mineral character. Stratton had been used to the white quartz around Silverton and allowed the evidently granitic character of the ore to divert him from recognizing its equally decided impregnation with iron oxide, from the decomposition of pyrite, leaving a vesicular quartz in which the gold lay hidden. However, in the usual haphazard way of prospectors, he had found a great bonanza. I saw it first in 1893, by which time Stratton had run a surface drift and an open cut, exhibiting a large width of medium-grade ore. It looked like the making of a big mine, and this was the view I expressed then to Thomas B. Stearns, of Denver, who was visiting Cripple Creek with me. Stratton was fortunate in securing John H. Mackenzie as his superintendent. A more experienced mine-captain he could not have found. Mr. Mackenzie stayed long enough to turn the promising prospect into a rich mine.

OUTCROP OF THE INDEPENDENCE VEIN, SHOWING A PORTION OF STRATTON'S SHAFT-HOUSE.

From 1891 to 1898 the output was worth $3,985,440, giving a profit of $2,402,164. As the mine gained in reputation Stratton received various offers of purchase. At first the enthusiasm of an owner led him to overvalue it, and by the time he had become accustomed to his wealth he felt disinclined to sell. As he said to H. H. Collbran, who built the Midland Terminal railway to Cripple Creek: "Look at this newspaper; there you are: 'The owner of the Independence'; 'W. S. Stratton, the great miner', and so on. If I sell my mine, where shall I be? and what shall I do? I don't think it is worth the $5,000,000 you offer, but if I change my mind I will let you know." That was in 1897. My own impression is that he was not in a position to appraise the mine, or any other mine of similar proportions. After Mr. Mackenzie left, he was not well advised, and I question whether his later superintendent was capable of valuing the property. Stratton really did not want to lose his prominence as the owner of a celebrated mine, and therefore did not take pains to put a price on it—not until he began to suffer in health. That was in 1898. Then he was approached by a broker of Colorado Springs, where he was living. To persistent pleading and persuasion the old man had to yield. He gave his promise to entertain a proposal, whereupon the business was presented by the broker to a financial corporation in London. Stratton arranged to go thither.

For the corporation, I made a thorough examination of the mine, taking five weeks and 1008 samples. The time and the number of samples would not now be considered unusual; in 1899 they were. My report stated that there was 70,000 tons of ore, having a gross value of $6,712,000. I stated that the mine could produce "at the rate of two million dollars of gold per annum for at least three years." But no valuation of the mine was given then, because none was asked. This was in March 1899. In April, when negotiations had been advanced, I stated, in reply to a cablegram, that the mine was worth "between five and six million dollars." A company was organized with a capital of £1,100,000 in shares of £1, of which 1,000,000 were issued. These shares were placed on the market at $10 and rose to $15. Stratton remained in control until a year later, that is, May 1900, when his interest was finally liquidated. Until then Stratton was managing director, with complete control of operations at the mine. Until he was finally bought out I had no executive authority. The conditions were anomalous and I had to make the best of them. Inclusive of dividends during the first year of the company's operations, he received exactly $10,000,000. It is an interesting fact that this sum was assumed to be equivalent to £2,000,000, on the rough-and-ready basis of $5 to the pound sterling; hence when the transaction was about to be closed, there was a scurry for the balance arising from the little difference between $5 and $4.85, amounting in this case to over £60,000.

At the time of purchase the mine was 900 feet deep; since then it has been deepened 500 feet more, but this vertical extension of the workings has only served to make the shaft a sump for the drainage of the neighborhood. No ore worthy of mention was found, except a patch followed by a winze below the 900-ft. level. It will be remembered that the workings transgress the steep contact between the granite and the overlying andesitic breccia. At the 1400-ft. level, only 250 ft. of breccia lies between the granite and the north boundary of the property. Prospecting in the granite southward has proved disappointing, although recently a little rich ore has been found on the ninth level in the granite. At the time of my examination the prospects in depth were considered negligible, and the showing on the ninth or bottom level was so poor that it was not sampled. Expectations of growth were based on lateral development, and the finding of parallel veins. This proved correct, for the output of the mine has come not from one but from a system of at least six principal veins with minor branch-veins, exhibiting a maximum enrichment between the third and fourth levels.

When Stratton ceased to control, I obtained executive authority and at once selected H. A. Shipman as manager, giving him orders to bring the assay-plans up to date. It was then ascertained that the estimates of later additions (based on data given, in the usual way, by the staff) to the ore reserves were incorrect. Into the scandal that ensued I cannot go, as it affects other persons. As regards the history of the mine, it is only necessary to say that as soon as a discrepancy was detected, by Shipman, acting under my orders, it was arranged (in October 1900) that John Hays Hammond and I should make a joint report, and that the sampling should proceed under the direction of Messrs. Shipman and A. C. Beatty, the latter then being my assistant. I went to London to attend the meeting of the company, and early in December I was actually on the steamer at Liverpool, about to return to Denver, when I was recalled by a telegram stating that Mr. Hammond had cabled an estimate. According to this estimate the mine contained only $2,300,000 in ore, from which a profit of $1,000,000 would be made. Since then the mine has yielded $12,000,000, from which dividends of $3,000,000 have been paid, not including the profit of the tributers ($1,000,000) and the money spent on the mill ($200,000). All this refers to the estimates of ore opened up in the Independence after the deal was made; it does not refer to the original report. It is true a suit was brought by the English company against the estate of Stratton (who died in 1901) on the ground that my samples had been 'salted', but no evidence for this was ever brought forward; to my knowledge and belief, it was baseless. The suit was thrown out of court.

Returning to the mine, the production between 1898 and 1904 was $11,046,947, from which $4,142,738 was paid in dividends. These dividends would have been at least 25% greater if the mine had not been gutted in an effort to force the share quotations. Under Stratton's administration and before he was paid in full—that is, in the 14 months from April 1899 to June 1900—the mine produced 48,048 tons, averaging $74.50 per ton, and paid $2,263,348 in dividends. In 1904 the mine was supposed to be exhausted, and the workings were let to tributers, who uncovered several rich orebodies and extracted $4,023,003, from which the company obtained $606,254 in dividends, from royalties received. Of the $4,023,003, at least 25% was profit to the tributers, so that the mine should be credited with paying $1,000,000 more. During these years some orebodies were found that there was good reason to believe had been hidden; the ore was extracted regardless of the safety of the mine; hence this series of operations ended in a general collapse of the workings from the surface to the fifth level. It is only this year that new levels have finally been extended through the caved ground, so that the whole of the mine is now open to further gleaning. Finally, the old workings having been gleaned, a successful effort was made to treat the dumps, which had been sampled under the direction of George A. Schroter. Subsequently, Philip Argall designed a mill, which was built in 1907-1908. This has treated 191,766 tons, yielding bullion and concentrate having a gross value of $423,050. Sufficient material remains to supply the mill for possibly a decade. Mr. Argall has been manager since 1908. At the present time the yield is at the rate of $750,000 per annum from 20,000 tons of mine ore and 200,000 tons of dump. Earnings of 20% are being made on a capital of $600,000. In 1908 the capital was reduced from £1,100,000 to £125,000. Thus the mine has yielded:

Period.	Tons.	Average per ton.	Gross Value.	Dividends.
A. ..1891-1898	41,694	$95.59	$3,985,440	$2,402,164
B. ..1899-1904	356,355	31.00	11,046,947	4,142,736
C. ..1905-1908	103,535	38.86	4,023,003	606,254
D. ..1909-1911	61,595	25.12	1,583,135	242,500
Dump	191,776	2.26	423,060	
	754,955		$21,061,585	$7,393,654

A. Stratton's ownership ....profit 60%
B. Stratton's Independence Ltd............ " 37%
C. Tributers .... " 15%
D. Tributers and dump-treatment........... " 12%

To these figures must be added the estimated profit made by the tributers or lessees, namely, $1,000,000, which raises the rate of profit during that period to 40%. Thus during the 20 years from July 4, 1891, when Stratton located his claim, to June 30, 1911, this mine has yielded 755,000 tons containing $21,000,000 worth of gold, from which a profit of $7,400,000 is recorded, but with promoters' profits, tributers' profits, and sundry other profits that would have accrued to an uninterrupted and capable owner, the amount yielded by the mine itself is fully $10,000,000. My opinion is that if Stratton had been offered $5,000,000 cash in 1899 he would have accepted it for the mine. At this price the mine could have yielded a profit of $1,000,000 per annum for 5 years, and would have yielded altogether fully $7,500,000, or 150% on $5,000,000 in 10 years. This would have represented a return on which the purchasers could undoubtedly have done well, for the shares of rich mines usually rise considerably above their intrinsic value. From a purely technical standpoint, however, I consider now that $5,000,000 would have been too much, for the purchaser of a gold mine is entitled to more than the return of his capital and 5% on it during the 10 years required for amortization. In 1899 the Independence was worth not more than $4,500,000, which, in 10 years, with efficient management, would have yielded from 160 to 170% in dividends, representing a return of the capital and 6½% per annum. This great bonanza is now practically exhausted. The details I have related constitute a small part only of a troublous history, for I have made no reference to ore stealing galore, to shooting underground, to devious litigation, to share gambling, and to other features of a story in which the romance is tawdry and the plot obscure. It suffices to quote Bret Harte, who said:

> "The ways of a man with a maid be strange, yet simple
> and tame
> To the ways of a man with a mine when buying or
> selling that same."

WHILE the salt-producing industry of the United States is important and well distributed, little or no attention has been paid heretofore to the possible occurrence of potash salts in connection with salt. There is a possibility, however, that potash deposits may exist in the eastern portions of the United States as well as in the arid region. The German deposits are in a region subject to comparatively heavy rainfall, the potash beds being, however, protected by an overlying clay. It should be noted, too, that the discovery of the Stassfurt potash beds was in the nature of an accident. The drilling which the German Government carried on for five years was intended for the development of the salt industry and the drill actually passed through a deposit of so-called 'abraumsalze,' compounds of potassium and magnesium, then considered worthless.

Stamp-Battery Cam-Shafts

By Charles T Hutchinson

The stamp-battery, like the poor, seems destined to be always with us, and, although many improvements in the various details of construction, have been made since the first description was written by Agricola in the early part of the sixteenth century, the underlying principles remain the same. There are still many features in the mechanical construction, however, that are unsatisfactory in their present form and for which no adequate solution has yet been found.

The most glaring mechanical defect lies in the weakness of the cam-shaft and the correction of this would do much to decrease the cost of milling. It is hardly necessary to go into the long list of troubles resulting from broken cam-shafts as the record can be found in every mill report but a discussion of the causes of breakage and a few suggestions as to possible remedies may prove to be of service. All of the breakages of cam-shafts are due either to crystallization or defective material, as it is a question whether anyone ever heard of a cam-shaft lasting long enough to wear out. The causes of breakage may be summed up and divided into two classes: the first group, in which a possible correction must be looked for in a change in the battery-frame construction itself; and the second group, in a change in the material that is used for making the shafts.

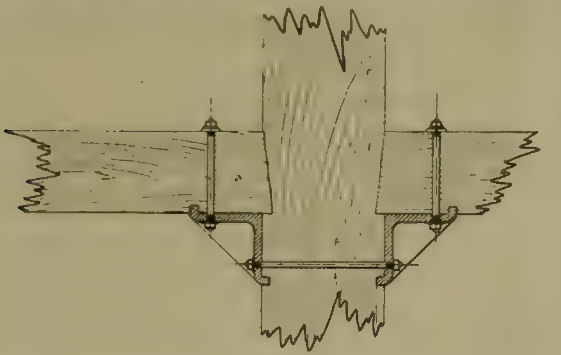

FIG. 1.

The first group therefore includes: (1) vibration of the battery-frame and foundation; (2) cam-shaft bearings out of true alignment due to the shrinking and warping of the battery-frame and the unequal settling of the foundation; (3) distortion of the battery-frame due to the defects in the ordinary back-knee frame construction, in which the ore-bin and the battery-posts are rigidly connected, so that unequal distribution of ore in the bin causes it to settle or cant to one side, pulling out of line that part of the battery-frame to which it is fastened. In the second group of causes will come: (1) vibration of the shaft due to the constant shifting of the load between the alternate lifting and dropping of the stamps and the varying order of drop; (2) shock due to the blows when the cams strike the tappets in lifting; (3) occasional hammering of the tappets on the hubs of the cams, which frequently happens when the millman neglects to shift the tappet higher on the stems to compensate for the wearing down of the shoes and dies.

To counteract vibration of the battery-frame and foundation will necessitate a change in the practice of the present day, in which wood posts are used almost invariably. Concrete has already superseded wood for mortar-blocks in spite of a great deal of opposition directed toward it when it was first introduced, and I believe it will ultimately do likewise for the battery-frame itself. The 100-stamp mill of the City Deep on the Rand has been the pioneer in concrete battery-frame construction, a detailed description of this mill having appeared before in the columns of the *Mining and Scientific Press*. It will be noted, however, that the designers of this plant have adhered to the old idea of attaching the battery-frame to the ore-bin by means of a knee-beam extending out from under the ore-bin and forming a cap on top of the battery-posts upon which the cam-shaft bearings rest. It would appear from a casual examination of this method of construction that any settling on the part of the ore-bin would most surely pull the cam-shaft boxes out of line.

Concrete is absolutely rigid and is not susceptible to alterations in form or position on account of any weather changes, and, if due care is taken in going down far enough to get bedrock upon which to set the mortar-block, there should never be any trouble due to cam-shaft bearings out of line.

The ideal form for the battery-frame of the future will be structural steel incased in concrete, the mortar-block and battery-posts being a self-contained unit and not attached in any way to the ore-bin. This type of construction will give rigidity and permanence without excessive first cost, and will undoubtedly do much to increase the life of the cam-shaft and improve the efficiency of the battery itself. It is altogether likely, however, that it will be a great many years before mill buildings adopt this method of construction, as the mining man is by nature conservative, and would look askance upon anything that looked like an innovation or change in the time-honored wooden-post construction.

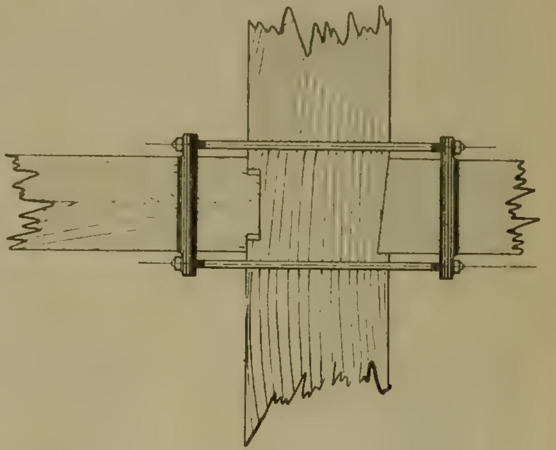

FIG. 2.

An improvement can be made, however, in the present method of fastening the knee-beam to the battery-posts. Fig. 1 shows the cast-iron angle brackets bolted to the posts and knee-beam, tying them rigidly together. Fig. 2 shows a somewhat different method of construction, which is a decided improvement over the former. As will be seen, the knee-beam is tenoned and bolted to the battery-post, the tenon having 1-in. clearance top and bottom. The anchor and tie bolts, while holding the battery-post firmly against the knee-beam, would still permit the knee-beam to settle or rise to the amount of clearance without throwing the battery-posts out of line vertically.

The three-post frame, in which the drive is on one end and the downward pull of the belt is supported on one side only, has a tendency to cause the shaft to jump in the bearing opposite the pulley. This is also one of the several causes that help to induce crystallization.

The four-post frame, however, having the pulley in the middle, and the pull of the belt therefore being supported on both sides of the pulley, obviates these objections and adds very materially to the life of the shaft.

C. O. Schmitt, in his contributed remarks on 'The Development of Heavy Gravitation Stamps', *Bulletin* No. 65 of the Institution of Mining and Metallurgy, does not approve of the four-post frame for the reason that, as he states, the torsional moment is a negligible quantity; but in my opinion the principal good feature about this type of construction is the fact that the pull of the belt is supported on both sides. There is, of course, one additional bearing, making four bearings to keep in line instead of three, but the question of keeping the cam-shaft bearings in alignment will never be satisfactorily settled until the concrete, reinforced, self-contained battery-frame construction is employed, and installed without being connected in any way to the ore-bin.

The question as to the kind of material that is best adapted for cam-shafts is a very difficult one to answer. Manufacturers do not feel inclined to do much experimenting at their own expense, and the mill buyer generally does not want to pay more for one cam-shaft than he does for another; but from my own experience I have arranged the different classes of materials that are used and might be used, as follows:

1. Heat-treated, chrome nickel steel.
2. Norway refined iron.
3. Hammered refined iron.
4. Inspected mild-steel blooms.
5. Ordinary merchant quality mild-steel blooms.

Of these five different classes, the chrome nickel steel is unquestionably the best material known to modern science for this purpose. The great strides that have been made in the automobile industry have taught the engineering world a great many things, and, as the function performed by the rear driving axle on an automobile more closely approximates the severe duty that is allotted to a cam-shaft than any other case I know of, it would appear to be good judgment and an almost sure exemption from further trouble if the same class of material could be used.

An alloy of chrome nickel steel, having a tensile strength of 200,800 lb. and an elastic limit of 144,900 lb., hardened at 1500°F. and drawn to 600°F., with an elongation of 8% and a reduction in area of 23%, should last indefinitely, and in spite of the fact that its first cost is about two and one-half times greater than for the shafts made of mild merchant quality steel, the increased service would undoubtedly compensate for the higher first cost many times over.

Norway iron is an excellent material for cam-shafts also, but the ingots obtainable in the United States are so small as to make it impossible to turn out so large a forging as a cam-shaft without a great number of welds. Nevertheless, a number of mills in Nevada are using shafts made in this way with far more satisfactory results than had been obtained heretofore when using the plain forged mild-steel shafts. Norway iron will seldom crystallize, but the great number of welds that must be made for so large a forging make it difficult to turn out a homogeneous shaft.

So-called refined iron as a material turned out commercially in merchantable quantities by the mills of this country suitable for forging into cam-shafts is practically unobtainable, as it has been almost entirely superseded by steel, and, while some small quantities of old iron shafting dismantled from mills and steamships built thirty years ago have been obtained by a few manufacturers, the supply is limited and must soon be entirely exhausted. Genuine refined iron, such as was produced by the puddlers of years ago before the advent of the steel age, is excellent material for cam-shafts, but it is hardly more common than the dodo itself, and in view of this fact one must needs be content with the alloy of steel best suited to the purpose.

Inspected mild-steel blooms forged under the hammer for cam-shafts are only fair material, and the ordinary merchant bar of mild steel should not be used under any circumstances for this purpose. Unfortunately for himself, the average buyer who is not familiar with the details, and for some occult reason does not care to pay a consulting engineer, considers nothing but price in placing his orders for machinery, and until the millennium arrives, machinery will continue to be bought on the basis of price competition, and the only possible way to eliminate this poor quality of material from the stock mill that is turned out by manufacturers today would be the consummation of an agreement between all the manufacturers themselves looking toward a standardization of stamp-mill specifications for the benefit of the user and for their own protection against many unjust claims for replacements.

The diameter of the cam-shaft for a given weight of stamp is another matter which has been determined by price competition rather than what is known by engineers to be the correct practice. A so-called 6-in. shaft (actual diameter from $5\frac{7}{8}$ to $5\frac{15}{16}$ in.) is used for a 1000-lb. stamp where ten cams are on one shaft. A $6\frac{1}{2}$-in. shaft should be used for this weight of stamp, actual diameter being from $6\frac{3}{8}$ to $6\frac{7}{16}$ in. While there is no doubt that if millmen and mill operators themselves were perfect machines, cam-shafts would last very much longer than they do, at the same time all are fallible and the cam-shaft itself should be made strong enough and heavy enough to give an ample factor of safety to provide for a certain amount of abuse and ill treatment. If mill operators who are having cam-shaft troubles—and what mill operator is not?—would substitute chrome nickel steel having physical characteristics somewhere near those mentioned above, they would undoubtedly save themselves a great deal of money and loss of time due to shut-downs. If purchasers of new mills would specify either chrome nickel steel in the same diameter as the manufacturer would specify—or, failing in this, to specify a shaft at least 10% larger in diameter than the standard manufacturers' specifications—they would take advantage of the ounce of prevention that is worth a pound of cure.

THE Cumberland plateau, which contains the coalfield of Tennessee, is a broad upland, standing about 2000 ft. above sea-level. While many of the streams flowing out to the east and west or to the south have cut ravines into this upland, still, as a rule, the ravines occupy but a narrow part of the area in contrast with the broad upland, which in many places is nearly flat, and in many others only slightly rolling. As a result of this condition, the coals have been rendered accessible at a large number of points; at the same time, they have been broadly protected, so that in many cases almost as large an area of beds remain as though they were entirely below drainage. In the northeastern part of the coalfield are many hills and mountains that rise from several hundred to a thousand feet or more above the general level of the plateau. These hills retain the higher coals that have been entirely removed from the rest of the field. They are remnants of the lands which were reduced to the general level at the time that the level of the plateau was established. But while containing these higher coals, as a rule, these higher mountains are often narrow-topped divides or ridges, so that the areas of coal they contain are relatively not as broad as those under the plateau proper. Fortunately, massive sandstones at various elevations tend to make the mountains broad shouldered, as it were, protecting larger areas of the high coals than in the corresponding mountains farther northeast, where the sandstones of that part of the section are less massive and resistant and the mountain divides are much narrower. As a rule, the level surface of the plateau has been maintained through the existence at these elevations of massive beds of sandstone. Lest it be thought that the sandstone has alone been responsible for the general flatness of the plateau, it may be noted that the plateau-level bevels a number of massive sandstones, as well as the intermediate beds of less resistant shales and shaly sandstones. This is well seen in Walden ridge, where the sandstone that protects the eastern edge of the plateau is stratigraphically 500 to 700 ft. higher than the sandstone, which protects the western edge overlooking the Sequatchie valley. At the eastern edge of the plateau there is a fairly even escarpment with a precipitous drop of about 1000 ft. At the western edge, overlooking the basin of middle Tennessee, there is a nearly similar drop, but the edge of the escarpment is not regular, but almost dendritic in shape, extending out in numerous headlands that inclose deep coves, and in a few cases the ends of these headlands have been cut off and stand out as isolated outlyers.—G. H. Ashley in *Mineral Resources of Tennessee.*

The Braden Copper Mines

By Pope Yeatman

*The mines of the Braden Copper Co. are situated in the Andes mountains, O'Higgins province, Chile, in about latitude 34° S. and 71° 20'W. The property is reached from Valparaiso, the seaport, by means of a broad gauge (5 ft. 6 in.) road as far as Rancagua, a distance of about 158 miles, and from Rancagua by the company's narrow gauge railroad, the length of which is about 43½ miles to the concentrator and smelter, and 1½ mi. farther to the mines.

The mining area consists of 101 claims covering 1214 acres. The legal status of all these claims is reported by the attorneys to be good. All titles come from the Government and are continued by the payment of the annual tax of ten pesos Chilean, per hectare (89c. per acre). Besides the mining claims, the company also owns about 35 acres of ground in the city of Rancagua, where the railroad terminal is situated, railroad right of way, right of way and water rights for the ditch line, power station, and power line.

The property had been worked by the Chileans for many years, operations being carried on in the Teniente mine and the rich hand-sorted ore either smelted nearby, transported to other Chilean smelters, or shipped abroad. Some concentration was done by means of hand-jigs on the richer grade of ore, but no attempt was made to operate on the low-grade ore found in the Fortuna mine. In April 1904 the property was purchased by an American company, and in May 1909 the present Braden Copper Co. acquired the ownership.

The mines are situated in a region of great ruggedness, on a part of the main range of the Andes mountains. All the rocks are eruptive. The country rock is andesite, surrounding a body of tuff, which represents the old crater of a volcano. This tuff, light gray in color, is no longer loose, but has been roughly cemented into a hard concrete-like rock mass. This represents material from a great volcanic outburst, which covered the old eruptive material by great thickness of volcanic ash, fragments of lava, and general ejectamenta. This is well shown in the tuff and volcanic agglomerate forming the core of the crater, made up of volcanic material of different sizes in the shape of more or less rounded boulders and shattered material, down to the finest impalpable powder, resulting from the violent ejection of material, part of which fell back into the same crater and was thrown out again and again, thus becoming abraded by contact. Solutions may have had some effect in the rounding of the different fragments, but the principal cause was abrasion. It is close to the contact, but in the andesite, that the main orebodies occur. It may be mentioned, however, that a part of the Teniente deposit occupies an old fumerole in the tuff itself.

The volcanic vent is practically circular in horizontal section; though owing to the great denudation on the north side, the outline appears to be oval rather than circular. The diameter of the vent is roughly 4000 ft. and the periphery measured along the outside is about 2½ miles. While in the main circular, there are many irregularities, due to the tuff filling breaks running out into the andesite. At numerous points around the rim of the crater, there are evidences of water sorting, giving a more or less sedimentary appearance to the tuff, and showing evidence of a probable crater-lake occupying the old volcanic basin. The slopes of the mountains are very steep; as much as 30% is often found. There is practically no vegetation, and a large part of the slopes are so steep as to be devoid of slide-rock.

The water-shed is toward Teniente creek, which joins the Coya at the smelter-site; the latter stream joining the larger Cachapoal close to the power-site, eighteen or twenty miles distant. Geologically, the mountain range is young, having supposedly been formed during Tertiary times, and while volcanic and solfataric action has long since ceased, movements of the earth's crust are still general, as indicated by the not uncommon earthquakes.

The orebodies occur around the periphery of the crater in the andesite, at its contact with the tuff. These occurrences represent andesite, which is more or less shattered and near the contact of the tuff often considerably brecciated, carrying the copper minerals in the cracks and openings. The mineral was deposited after the time of great volcanic disturbance, "during the closing stages of igneous activity and is aqueo igneous in development." The minerals making up the ore have been deposited from ascending hot solutions, mainly filling cracks or replacing some of the constituent minerals of the andesite. The richer portions are apt to be where the greatest brecciation is, except where the brecciated material has been closely filled with tuff, "originally in the form of mud forced into the interstices of the breccia as an emulsion."

In the case of the Teniente 'pipe,' which represents an old hot-spring channel, the loosely agglomerated boulders of tuff and breccia have been coated by mineral, either deposited in open channels or replacing some of the tuff itself. Denudation of the surface has been in some cases more rapid than oxidation, and the sulphide zone often reaches to the surface. In the case of the Teniente pipe, however, oxidation has been carried to a considerable depth, and hence a good deal of mineral is secondary, there being considerable chalcocite and especially cuprite and metallic copper; these latter minerals being by no means so common in the Fortuna section.

The orebodies are limited on one side by the tuff, but in the andesite the line of division is, as a rule, poorly marked; instead of being determined by distinct planes the limit is determined rather by the commercial features. In other words, on passing from the brecciated material into the fractured andesite, the content of copper becomes gradually less and fades out in the more blocky andesite country rock. The orebodies dip at about 70° toward the centre of the crater. Three so far have been worked on: first, the Fortuna; second, the Teniente; and, third, what is known as the Fortuna No. 4. All of these showed strong outcrops, stained with copper minerals. Besides these strong indications are others, one to the east of the Teniente main workings; another the Soldado, farther to the east and south; and still farther south, the Caballeria No. 1 and No. 2, and the Rejimiento, and it is where these indications are shown that future development is planned.

In order, as carefully as possible, to gather all the geological facts bearing on the ore deposits, besides a careful study in the field, numerous samples were taken and submitted for microscopic examination; C. P. Berkey of Columbia University undertaking the work. I can say that Mr. Berkey corroborated my previously expressed views concerning the orebody, in the direction of continuation of commercial ore to a considerably greater depth and to the fact that the copper content is mainly in primary minerals rather than in secondary.

Metallic minerals are iron pyrite, magnetite, chalcopyrite, bornite, and secondary chalcopyrite, a mineral said to resemble tetrahedrite and zincblende, in the sulphide zone; and in the zone of oxidation, limonite, cuprite, metallic copper, and the carbonates and silicates of copper. The principal non-metallic minerals, outside of the original constituents of the rock are, tourmaline, quartz, ankerite, calcite, chlorite, sericite, mica, epidote, and zircon.

The depth to which the profitable orebodies will reach is an important and naturally difficult question to determine with any degree of accuracy. The indications, however, point to a considerable depth, much greater than has been reached at the present time, and will be in the main limited

---

*Abstract of a report to the company, September 1, 1911.

by the compactness of the rock and lack of fracturing, due to the great depth below the original surface at the time of the formation of the orebodies. The difference in elevation between the highest outcrop at Caballeria and No. 4 level, where commercial ore is found, is about 2500 feet.

The Teniente pipe, which has been followed to within 300 or 400 ft. of the level of Teniente No. 3, showed open channels and indicated great freedom in the passage of the hot solutions. No. 4 Fortuna also shows open texture. However, the few evidences seen are invariably in favor of much greater depth, and as the value of the copper is due to its being mainly in the form of primary minerals, rather than secondary, much change in grade, due to increased depth, is not expected.

It may be said that while chalcocite does occur in the Fortuna, it is limited in amount and apparently occurs as a thin coating on pyrite and chalcopyrite, increasing the grade only in a small way. The Teniente pipe represents a different condition, for here there has been considerable secondary action, and the rich bonanzas have been mainly due to secondary cuprite, metallic copper, and chalcocite. At greater depth, the lower-grade minerals, chalcopyrite and bornite, will probably be reached, and instead of the bonanza of the upper worked-out portion, there should remain ore carrying bornite and chalcopyrite, but more concentrated than in the case of the Fortuna ore.

A thorough and careful geological survey was made of the deposits in 1910 by my assistant, Robert Marsh, Jr., with a supplementary study in 1911. Operations have been conducted on three distinct orebodies, each one of which differs considerably from its neighbor, but all of which have points in common resemblance.

The Fortuna mine was originally opened in the search for rich ore, the strong copper stains of the outcrops leading the original prospectors to hope for high-grade ores similar to those found in Teniente. These prospectors opened up a considerable extent of ground, but reached no great depth, nor did they find much high-grade ore to pay for their labors. Their work, however, showed the American company what to expect, and led them to concentrate their efforts toward the development of this property.

The Fortuna orebody is typical and is represented by a body, lense-shaped in horizontal section, as far as developed, about 1500 ft. long, with a maximum width of 260 ft., and of an unknown depth, but so far developed to the No. 4 level, a distance of 1421 ft. below the upper part of this orebody. The ore lies partly in the fractured andesite and partly in the breccia. At the south end there seems to be a constricted area, where the brecciation and fracturing is less marked. It is hoped that in driving along the contact of the breccia and tuff, conditions may arise favorable to an enlarging of the constricted area into still another body. The second and third levels have been well developed by the main adits and by numerous cross-cuts and stopes. Both levels are being operated.

The ore of No. 4 Fortuna orebody occurs in a highly shattered zone of open texture with little or no fine cementing material. The copper is found mainly in the minerals bornite and chalcopyrite in well developed crystals associated with ankerite and quartz. The orebody is now being developed and has shown a length of 55 metres. The ore is being raised on and is still continuing at a height of 42 metres. The indications are good for considerable height of ore above the level, and a considerable depth.

The Teniente orebody outcrops in the crater of the old volcano and shows high-grade ore at the surface. The copper occurs in the form of malachite, azurite, chrysocolla, cuprite, metallic copper, bornite, and in the deeper workings, chalcocite. The old prospectors followed the bunches and stringers of ore in the 'pipe' and in seams running from the 'pipe' to a very considerable depth, but were finally driven out by water.

While the 'pipe' seems to have narrowed with depth, the ore is still said to continue. At the present time, however, the company has not been able to examine this below 150 ft. below the No. 1 Teniente cross-cut. Above this the rich ore has been extracted, but there is still some concentrating ore, which it did not pay the old operators to mine. This ore, however, is considerably oxidized and will make a poor product for concentration, and will besides require a good deal of hand sorting. At greater depth, however, the oxidation will decrease and more sulphides appear. The original concentration of high-grade sulphide was further enriched by secondary deposition from descending solutions.

The pipe, occurring wholly in the tuff and agglomerate, appears to be rudely shaped like an inverted cone. It has a dip of about 45° northeast from the surface to the adit level; from there steepening to 70 to 80°. The ore in the pipe so far mined has been largely secondary, and there has been considerable enrichment, due to the leaching of ore higher up and re-precipitation of the leached copper. The constitution of the material in the volcanic pipe being a loosely formed agglomerate, has allowed the free passage of solutions and has made possible oxidation at greater depth, due to descending waters, as well as easy passage for the original hot ascending solutions.

When the present company took possession of the property, the shaft below the No. 1 adit-level was full of water, and an attempt was made to unwater this, but without success. Since then, however, the shaft has been drained, probably through the approach of the No. 3 Teniente. Owing to the fact that the shaft was filled to half its depth with débris, the bottom of it has not yet been examined. It is to tap this that the No. 3 Teniente is now being driven, but that adit will also be used to look for ore in the fractured andesite to the east and north of the old workings. A raise of about 300 ft. will be necessary to connect the bottom of the shaft with the No. 3 Teniente.

For extracting the ore a modified caving system is being employed, and in preparing the mine for this work the stopes are started by the overhand method, the stopes remaining filled with broken ore on which the men work. Pillars are left between the stopes and these will afterward be caved or broken out. Previously cross-cuts were driven at distances of about 17 metres, centre to centre, and the centre line of the stope was then fixed over them. These stopes have a width of 9 metres, leaving a pillar of 8 metres between. The major axis of the stope was at right angles to the contact. Where the lens was not very wide, a stope was made, running in the direction of the length of the lens, rather than across it. The ground stands well and breaks well, and no timber is required except where box holes are made.

In the past, ore from No. 2 and No. 3 Teniente was carried down by two separate aerial tramways to the main loading station, from whence it was taken by another aerial tramway to the concentrator. No. 4, 3½, 3, and 2 Fortuna are connected by raises and all ore will be dropped down to the No. 4 level and loaded into cars, and from there transported to the ore-bins supplying No. 5 level, from which it will be carried direct by electric tramway to the concentrator. The Teniente mine will also connect through No. 3 Teniente, No. 1 cross-cut, and No. 4 Fortuna with the main ore-bin in No. 5 Fortuna.

A very careful measurement of the tonnage of ore developed and the value of the same has been made, and the following is a summary, as at July 1, 1911:

	Tons.	Per cent Cu.
Main Fortuna orebody, to 30 metres below No. 3	7,077,986	2.90
Additional ore developed by No. 3½ up to June 30, 1911	2,721,808	2.70
Fortuna No. 4 orebody	212,312	3.58
Teniente No. 3	62,510	2.38
	10,074,616	2.85
		say 2.70

In the past stoping was done mainly by hand, but it is proposed to carry this on by small hammer-drills. Driving is done by air-drills and by hand, but when in full operation, machine-drilling will be almost exclusively em ployed. No hoisting of ore will be necessary, as the orebodies can be more easily reached through adits. Ventilation will also be easy, and there should be no trouble on account of water, as all draining will be done through the different adits. Still greater depths can be reached by longer adits. For instance, an adit about 6000 ft. long driven from a point close to the mill would tap the Fortuna orebody at a depth of between 800 and 900 ft. below No. 4 adit, the deepest ore now developed.

No. 3½, to judge by development already proved on that level and levels above, should open up another two and a half million tons. No. 4 Fortuna has also shown commercial ore below No. 3½, but development has not progressed far enough to allow estimate of grade. It promises well and will add greatly to the tonnage. The grade so far encountered is commercial, though not as high as the average on account of being on the foot-wall side of the orebody. Roughly, about 1,500,000 tons may be considered as partly developed by No. 4, September 1, 1911.

In determining the results, ore running less than 2% copper was excluded. It has been figured that ore even as low as 1.5% will give a profit at 12¼c. copper. The density of the ore was determined and 12 cu. ft. in place was found to be equivalent to one ton in weight.

In determining Fortuna No. 3½, 100 ft. below the level was included. For the No. 4 Fortuna orebody, allowance for a block of ground extending 50 metres above and 15 metres below the present level was made. No ore is considered as developed in No. 1 Teniente. Teniente No. 3 is all 'probable ore.' No allowance is made for any ore in the old portion of the Teniente, although undoubtedly considerable will be recovered from the old workings. Nothing, of course, has been considered in connection with the Soldado, Capitana, Caballeria No. 1 and 2, or Rejimiento.

Careful sampling has been done by the mine management and this has been satisfactorily checked by individual engineers—namely, Harold A. Titcomb, J. A. McCaskell, and Allen H. Rogers. Sampling was done at comparatively short intervals, and these intervals, considering conditions, have proved to be sufficiently close. The ore is so homogeneous in different sections that even a poor sampler would be expected to get approximately the same results as a more expert one, and to this homogeneity of the porphyry ores has been due the close agreement as to assay values by different engineers making an examination of the porphyry properties in the State.

The future 'possibilities' for ore are most promising—first, in the direction of new orebodies, indicated in the several copper-stained outcrops around the periphery of the crater; second, in the very promising ground along the contact, close to the old Teniente workings; third, the most important of all, the continuation of the present developed orebodies, main Fortuna and No. 4 Fortuna, to considerable depth. The belief in this continuation is based, first, on the geological features to which the formation of the orebody is due, namely, the formation of the ores from ascending solutions rising from considerable depths, just after the violent volcanic disturbances; and secondly, to the fact that most of the copper minerals from which the deposits obtain their value are essentially primary, to the extent of their dating back to the original process of silicification and mineralization accompanying igneous activity. The copper minerals occur more as vein fillings than as replacements of original rocks, and are not dependent upon secondary enrichment from downward percolating solutions, which have leached out the copper minerals at higher horizons and redeposited the copper in mineral form, and thereby enriching the poorer primary ores.

It is interesting to note that the ore shown on the second level of the Fortuna is practically of the same assay value as that on the No. 3 level, though the latter is 275 ft. lower than the former; and No. 3½ averages little lower than No. 3, though 328 ft. deeper. Assays for this level so far show an average of 2.56%. No. 4 Fortuna orebody is at a much lower geological horizon, but shows even higher content, due probably more to local conditions than to anything else. The Teniente pipe will probably show a lower content in depth than in the upper portion, where there is considerable secondary enrichment, due to cuprite, metallic copper, and secondary chalcocite. Later development in No. 3½ and No. 4 Fortuna seems to show an extension of the ore toward the east, which will bring in an increased tonnage of lower grade ore. The raise from No. 4 to No. 3½ has shown a considerable area of low grade ore extending beyond the main body.

At the mine, offices, store, quarters for the foreign employees, and for the native workmen, have been erected. The native miners are mostly quartered at the different adits in large rooms, cut out of the country rock, there being no place on which to erect buildings nearby on account of the steep rocky slopes. At the No. 4 level is situated the compressor plant and electric station, operated by power from the Cachapoal power-plant, and here also are the blacksmith and repair shops.

Supplies have been brought to the mine either by wagon or by aerial tramway, and on this latter the ore is carried to the mill. Later, however, transporting will be done by electric trolley line, run from No. 5 adit to the top of the ore-bins at the concentrator, and this trolley line will be connected with the main railway by an incline at the east end of the concentrator. Water for all domestic purposes is obtained from Teniente creek, which is ample for all requirements.

Underground haulage is at present done by means of small cars, either pushed by hand or hauled by horses. Arrangements have been made, however, for electric traction, and electric locomotives and cars are on the ground, and larger electric locomotives are to be employed to transport ore from the No. 5 adit main ore-pockets to the top of the concentrator, over a line about three kilometres long.

Owing to the numerous snowslides, it was naturally felt that a surface line would be dangerous, but after looking over the ground very carefully, it is believed that the proposed line will be better than aerial trams, but snowsheds have been erected to avoid the danger from delays caused not only by slides but by drifting snow.

From a close study of the ore and from experience in the treatment of somewhat similar ore in Nevada and Utah, plans have been made for a concentrator, and the plant is now under construction. It is designed on lines somewhat similar to the Utah and Nevada plants, but with coarser preliminary crushing and with the introduction of jigs to catch the coarse mineral. The plant is designed for crushing with gyratory crushers and rolls, screening by means of shaking-screens; treating the product on roughing and cleaning jigs of the Woodbury type, regrinding the tailing in Chilean mills, classifying the finer sizes, and treating same on Wilfley tables and Frue vanners. The concentrate will be delivered either to the smelter or to the roasting plant, should leaching of the concentrate be decided on.

The coarse-ore bins will have a capacity of about 1400 tons. From the bins the ore will be carried on belts to the crushers, of which there will be two No. 7½ gyratories, two 48-in. rolls, and six rolls of 36-in. diameter by 15-in. face. From the crusher station the ore will be delivered by belts to the fine-ore bins, about 4000 tons capacity, and from these by belts to the mill itself.

The concentration will be done in two separate mills, the first of three units, each unit having a nominal daily capacity of 533 tons. The second concentrator represents an enlargement and re-design of the present concentrator. It will have a nominal daily capacity of 400 tons. These two mills will be brought up to a daily capacity of 3000 tons. The mill has been designed so as to allow for expansion at either end if plant is increased.

All power used will be electric, generated from the Cachapoal ditch and power-plant. The water-supply for operating the concentrating machinery comes from ditches taken from the Coya and Teniente creeks, at an elevation much above the millsite. In the past, flumes supplied water for milling and also for power, but the volume is not sufficient for the increased installation, and hence the necessity for the new power-plant.

It is confidently expected that an extraction in the mill better than 65% will finally be obtained, and this in spite of the fact that the extraction in the old mill was much below that amount, partly due to a less favorable design, to overcrowding of the different machines, to uneven feed, to poor classification, to a variable amount of oxide, carbonates and silicates of copper, and to possibly an attempt to make too clean a concentrate, and by so doing increasing the losses.

The re-designed mill has been put into operation. Of the new three-unit plant, the first unit is finished and almost ready for operation, and the foundations, buildings, etc., for the other two are completed. The coarse-ore bins, the crusher station, all but the erection of a few rolls and one-half the fine-ore bins, are finished. All the material is now on the ground for the completion of the entire plant. While the old mill is supplied with crushing machinery, the main crushing plant will eventually do the entire crushing. The ratio of extraction will be about nine into one. The average analysis of concentrate will be approximately as follows: silica, 24%; alumina, 12%; iron, 19%; CaO, 2%; sulphur, 22%; copper, 16%.

Smelting operations have been carried on to a limited extent and have proved that the concentrate can be easily smelted at a reasonable cost. This smelting was done under most unfavorable conditions, especially as to the size of the furnace and with a furnace of improper design. The old practice should be greatly improved. A plant has been designed, consisting of a blast-furnace, 44 by 180 in. at the tuyeres, with a 7-ft. ore-column, and a Pierce-Smith basic-lined converter for converting matte into blister. The building allows for two blast-furnaces, both of which can be larger than the one mentioned, and also for an additional converter. The smelter power-plant consists of a Nordberg blowing-engine large enough for two converters and a No. 7 and No. 9 Connersville blower for the blast-furnaces.

Experiments made during the past year have proved, with converter slag returned to the blast-furnace, the concentrate to be almost self-fluxing and requiring but little lime as a flux. The alumina in the concentrate is mainly combined with silica in feldspars and acts as a base, making a fusible slag. A briquetting plant is under construction, so that concentrate will be bricked before charging.

The plant is so designed as to make possible a great increase in capacity should it be so desired. Office buildings, assay office, machine-shop, carpenter-shop, hotel, quarters for the officials and married foreigners, and quarters for married natives have been erected. A telephone system has been put in, connecting the offices at Rancagua with the power station, concentrator and smelter, and mines, with local systems at the above-mentioned places. There is also a separate line connecting the power-plant and sub-station, and there will also be a separate line for the railroad.

It has been decided to put in a leaching plant capable of treating the concentrate from one-fifth of the daily tonnage. Numerous experiments on a working scale have been made in America on concentrate from the Braden Copper Co., which have been most successful, and should the same success be obtained in Chile, on a much larger working scale, it is estimated that the cost of production per pound of copper will be very materially reduced.

This leaching plant will consist of one Wedge furnace with acid tower and accessories, three leaching-vats, three settling-vats, nine solution-tanks, and a precipitation-plant of ten tons cathode copper capacity per day, which, should leaching not be carried out, would be used for refining a certain portion of the blister-copper from the blast-furnace. The electric precipitation-plant will probably be increased so as to handle copper either from the blast-furnace or leaching-plant. What makes the method of treating the concentrate by leaching so attractive is that it is believed the costs will be lower and extraction higher, and the basis for the low costs is the low cost of power produced by the water power installation on the Cachapoal.

The estimate of costs is based on what has already been done at the Braden Copper Co.'s mines in a small way during the more or less experimental stage, and on costs obtained at other properties of a similar character—the difference in conditions being, of course, considered. It takes in all disbursements necessary for operations and includes, in addition to all possible expenses in Chile, also New York expenses. Instead of putting in an item of 'general expense', such expenditures are included under the several headings.

In the estimate the following factors are taken as a basis from which to figure:

Average assay, 2.70% copper.
Mill extraction, 65%; smelter, 95%.
Yield of copper per ton of ore, 33.5 pounds.
Average ratio of concentration, 9 into 1.
Average price per pound of copper, 12½ cents.

	Per ton of ore.
Mining	$0.700
Transport to mill	0.100
Milling	0.500
Smelting at $5 per ton concentrate (9 into 1)	0.550
Converting at $8 per ton blister	0.134
Refining at $15 per ton blister	0.251
Freight at $12 per ton blister	0.201
Commission, etc.	0.043
Total	$2.479
Cost per pound copper	$0.074
Profit per pound copper	0.051
Profit per ton of ore	1.708

It is thought that leaching and electrolytic precipitation may reduce the cost per pound of copper by ½ to ¾c., but this will require additions to the plant, which will not, however, be recommended before a thorough working test on a large scale is made on the ground, with a plant for that purpose now in course of erection.

Allowing a production of 3000 tons per day, and 360 working days in the year, the total tonnage treated would amount to 1,080,000 tons. A yield of 33½ lb. of copper per ton of ore at a cost of 7.4c. per pound, and copper at a price of 12½c., would give an annual profit of $1,844,640. For each cent increase in the price of copper there would result an increase in the profit of about 19.6%. Until the bonds are converted into shares the profit to be divided among the shareholders is estimated as follows:

Annual profit as shown above		$1,844,640
Interest on $4,000,000 bonds at 6%	$240,000	
Interest on $3,000,000 bonds at 7%	210,000	
		450,000
Balance to be paid on shares		$1,394,640

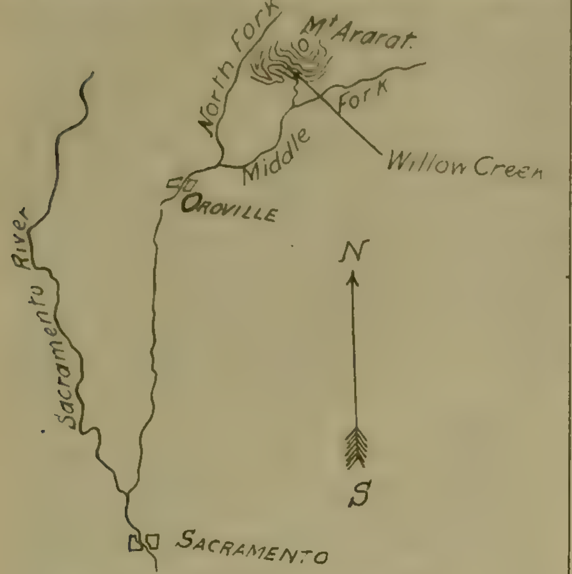
With 1,200,000 shares issued, the profits per share will amount to $1.16, or 23.2% interest on the par value. With all bonds paid off and allowing for an issued capital of 2,800,000 shares, the annual profit per share would be at the rate of $0.658, or on the par value of the stock, 13.1%. These figures allow for depreciation, which would be taken up in the costs, but not for amortization.

FIGURES compiled from official sources tend to support the contention of the United States Steel Corporation that it by no means monopolizes business in steel and iron. For instance, competing with the National Tube Co. are independent companies with a capacity of 939,000 tons. The Steel Corporation's actual output, in 1910, of tube products was 868,000 tons. Competing with the American Sheet & Tin Plate Co. in the manufacture of sheets and tin plates are 45 well known independents with a capacity of 1,286,000 tons, against the Steel Corporation's actual output in 1910 of 1,083,000 tons. Competing with the American Steel & Wire Co. are 17 independents with a capacity of 1,707,500 tons, against the Steel Corporation's actual output, in 1910, of wire rods and wire of 1,624,000 tons.

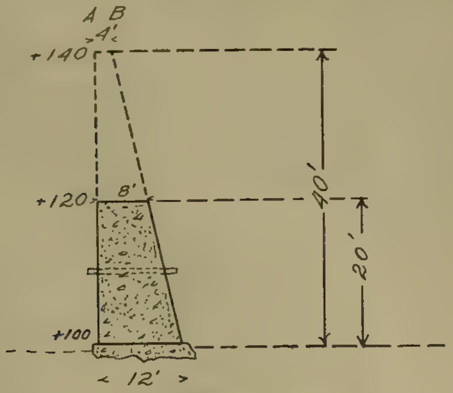
Building the Gold Mountain Dam

By F. A. Post

The concrete dam erected under my superintendence by Gold Mountain Hydraulic Co. on Willow creek, Plumas county, California, was built in compliance with the State law providing that every mining company using the hydraulic process of mining on any of the tributaries of the Sacramento or San Joaquin rivers must provide ample protection of the streams below its place of action against deposits of tailing. The California Débris Commission is the authority to prescribe or to approve the devices for the protection of the streams, and without its sanction no operation by hydraulic methods is allowed. The accompanying sketch map shows the relative position of Willow creek in the Sacramento river basin.



MAP SHOWING POSITION OF DAM.



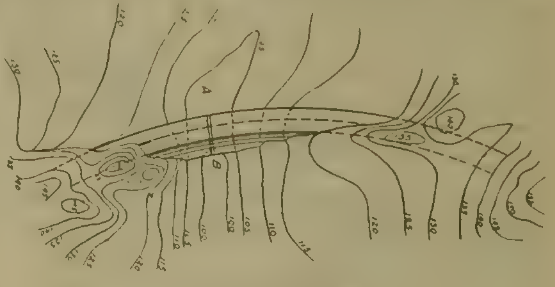
CROSS-SECTION OF DAM.

The situation of the dam, its size, plan, and cross-section were approved by the California Débris Commission in October, 1910. The elevation of the site is 5000 ft. above sea-level. The early snow and frost of the past autumn obliged the company to postpone construction till this year. The work could not be started before August, because the snow along the mountain road leading to the place thawed only in June, and during July the manager of the company was engaged with negotiations with contractors and settling with workmen. Thus the work was begun early in August.

The dam in plan is a circular arch, whose up-stream face is described by a 160 ft. radius. Its total height is 40 ft., but it was decided by the Débris Commission to require at first the immediate erection of the part of the dam up to the height of 20 ft., provided that the company in course of time and in accordance with the real amount of deposits, will gradually raise the dam to the height of 40 ft. The up-stream face of the dam is vertical, the down-stream one having 1:5 slope. The thickness of the crest of the dam is 4 ft. at the elevation of 40 ft.; thus its thickness at the bottom equals 12 ft. The amount of débris which can be stored behind the dam was figured as follows:

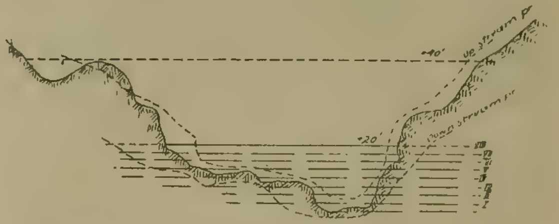
Height of dam, ft.	Capacity of reservoir, cu. yd.
20	35,000
25	95,000
30	130,000
35	300,000
40	440,000

Taking into consideration the fact that with the company's outfit it is possible to wash no more than 1000 cu. yd. per day, that only 25% of washed ground can be brought to the reservoir as a sediment, and that only during approximately 100 working days can the hydraulic process be used in this district, it can be figured that the dam has ample provision for débris, from $\frac{35{,}000}{1000 \times 0.25 \times 100} = 1\frac{1}{2}$ years, to $\frac{440{,}000}{1000 \times 0.25 \times 100} = 17\frac{1}{2}$ years; or in round figures from 2 to 20 years to come. According to the specifications, the dam should be erected of concrete, of the proportion 1:3:6, adding to that mixture during the process of construction not over 25% of hand rock. The required materials and the workmanship must be of first-class quality.



PLAN OF DAM-SITE.

It was August 10 when I arrived at the damsite. Part of the cement (in the neighborhood of 400 sacks) was already delivered. The concrete mixer and other tools had to be delivered next afternoon. The first step, the exact location and staking of the proposed dam, was made on the same day, with the assistance of a concrete-man and two carpenters. The place for building was rough and covered with numerous boulders of different sizes. Some of these boulders were more than 8 ft. diam. The ordinary method of staking would not be proper here; we were obliged to stretch a wire across the creek at an elevation of 30 ft. or so. The projection of this wire was taken as an axis of coördinates, and the perpendicular to that axis at the point of intersection with the bottom of the creek was taken as another coördinate axis. From these axes, by means of



CROSS-SECTION OF DAM-SITE.

two plumb-bobs, we could project on the ground any chords or middle ordinate of the arch of the given radius. After a few trials it was found that the best direction of the axis of the dam was about S.40°E. With this direction and at an elevation of 20 ft. the dam strikes two solid cliffs of diorite, about 70 ft. apart. The solid rock foundation was found close to the surface under the footing of the dam.

The clearing of the site from boulders, bushes, and dirt was commenced immediately after locating the dam. Shovels and axes were used to remove the dirt and bushes; picks and giant powder were used to dispose of the boulders and weathered portions of rock. By these means the footing for the foundation of the dam and for the abutments of the skewbacks of its arched parts were prepared. During the same day the question as to gravel and sand was decided. There was found above an old crib dam, which is situated 200 ft. upstream from the place of construction, a layer of mine tailing, about 3 ft. thick, over 100 ft. long, and about 50 ft. wide. This layer represented a good mixture of small stones, gravel, and sand, with about 10% of impurities; the main impurity was a fine red clay. The proportion of gravel and sand was nearly the same as required by the specifications. The flowing water of a spring running through the place made the work of washing the mixture very convenient. The first lot of cement, like all cement delivered afterward, had the brand of the Mount Diablo Co. The cement was delivered in good condition, without lumps or any impurities, of good uniform color, and finely ground. The rough test with cakes made of that cement had indicated no faults whatever in the samples taken from each lot of 100 sacks. During the first day and part of the following one a tent for twenty men, a kitchen, and a storeroom for instruments and materials were erected.

The next day, August 11, the concrete mixer, with gasoline motor, was brought to the place of construction. The arrangement of the concrete plant, the providing of the continuous water-supply, and preparation of the footing for the dam foundation occupied the whole of that day. The plant was placed 80 ft. upstream from the dam. A terrace 15 ft. above the foundation of the dam was dug in a convenient place on the west side of the canyon. It was first planned to dig out the terrace for the plant a little higher, thus allowing the delivery of the concrete mixture from the plant to the work with more ease and without the necessity of raising the scaffolding during the work; but that idea was soon abandoned. The rough leveling of the canyon above the dam had shown that the head of the spring, 600 ft. distant, was just enough to bring the water to the plant at the selected spot. The spring water was piped 600 ft. to the plant by means of steel-riveted pipes, partly laid on the ground and partly supported on light trestles made of 2-in. boards. None of the trestles was higher than 10 ft., most of them being from 2 to 4 ft. high. At the upper end of the pipe a kind of earthen diversion dam about 3 ft. high was built to force the water into the pipe, and a tappoon made from 1-in. boards was placed here. It served as a regulating gate. Another piece of board, supported by two short scantlings embedded in the body of the earthen dam, served as a waste gate. This last gate was used with success several times, and saved the earthen crest from scouring by overflowing water.

The mixer, with gasoline motor, weighed over 5000 lb., and it was not an easy task to handle it on the mountain road. It was delivered from Sacramento by the Western Pacific railroad to Quincy (the county-seat), and thence to Gold Mountain, twenty miles distant. To make this last delivery a 6-horse team was employed for two days. The capacity of the machine, with attached 6-hp. motor, was about 50 cu. yd. per day. In reality the highest output of the machine during the work never surpassed 35 cu. yd. per day. The strength of the motor allowed the mixing of no more than three wheelbarrows of concrete material at a time; that is, about 8 cubic feet.

Before the beginning of the cement work a full-sized pattern of the cross-section of the dam was prepared, and the templet for laying the curve of 160-ft. radius was cut from a 1-in. board. The length of the pattern was of 21-ft. chord, with middle ordinate of 4 in. The studs in the forms and scaffolding were made of 3 by 4-in. lumber, the sheathing of 1-in. boards, and the platform and the trestle floor of 2-in. boards. To divert the stream water, which passed along the bed of the creek, a 15-in. pipe was put on the bottom of the dam footing. This pipe, according to the project, had had another purpose, namely, to serve as a safety sluice during all the time of construction. It had to be blocked only after the final setting of the dam. The hand-rock was provided partly during the preliminary work of clearing the place, partly by blowing up the cliffs on the adjacent slopes of the creek; if, after the explosion, the blocks of stone were still too big for handling, they were broken by sledge-hammer and drill, or blasted up again by giant powder.

As stated before, the surface water was completely diverted from the foundation by a 15-in. pipe. But soon it was discovered that water was coming from several cracks in the rock, and that it was impossible, with the implements at hand, to dispose of the water unless the ground-springs were stopped. The bedrock prepared for the dam footing was so rough and irregular that the construction of the form could not be started conveniently. Therefore it was decided to fill all underwater cracks and cavities with rich cement mortar, and to level the bottom by putting on a layer of cement about one foot thick. All lumber for that work was cut on the premises of the company, and sawed by the company's sawmill, one mile from the dam. The running expenses of this small sawmill were so high that the lumber used for the dam cost $15 per 1000 feet.

On August 12 the concrete work was begun, by putting on the layer of concrete, which was designed to stop the bottom springs, to make a good connection between bedrock and dam, and to raise the level of the bottom just enough to start the erection of the form. The first five sacks of cement were used, for the preparation of a rich concrete mortar, 1:2; the next ten, 1:4; and the last fifteen, 1:6. All these mixtures were put dry one after another, and evenly spread in the standing water covering the bedrock from several inches to a foot and a half deep. Only with the last portions of the mortar were a few cubic feet of hand-stone thrown in the wall. This work was accomplished in three hours in the forenoon. Altogether there were placed 175 cu. ft. of concrete, and the top of the work reached the 7-in. mark above the datum. In the afternoon carpenters started the erection of the forms, while all concrete-men were set to work on the construction of the water-line. Beginning with August 13, the concrete work was going every day, Sunday included; and on August 22, twelve days from the beginning, the work was finished. Work was usually begun at 7 a.m. and lasted up to 5 p.m., except one hour for dinner. Thus the length of a working day was 9 hours.

Very often the concreting was stopped for half an hour or so by some kind of fault in the gasoline motor; two or three times by some defect in water piping, and twice for a couple of hours by the necessity of raising the 75-ft. unloading-platform which was supported by the trestles. In general, the order of the work was as follows: 3 men were digging the gravel and loading it on wagons; 2 four-horse teams carried this gravel to the platform, where washing and mixing were operated by 3 men, who also loaded the washed sand on wheelbarrows, and unloaded from the wheelbarrows to the receiver of the mixing machine; 4 men carried the prepared concrete and placed it in the form; 2 men were busy with procuring the hand-stone and with bringing it to the work; 1 man was always with a shovel on top of the concrete wall, spreading the concrete and placing the stones in the best possible manner; one machinist attended to the work of the mixer and gasoline motor; 2 carpenters worked on the preparation of the forms and raising the trestles. Thus 16 men and 2 four-horse teams were employed on the work. Besides that, 2 men were working at the sawmill and 2 four-horse teams were delivering the cement from Quincy. One Japanese cook was hired to board the men. The cost of the work of these 5 men and 2 teams was included in delivery and boarding expenses.

The loading, unloading, and washing of the gravel was done with ordinary miners' shovels, having pointed ends and long handle. Picks, axes, bars, drills, and sledge-hammers were used for the cleaning of the ground and breaking the stones. As to the water supply, it was carried to the platform by steel riveted pipes, 7 in. diam. These pipes were made of No. 14 sheet iron, their length 16 ft each. The pipe line was carried by inserting the taper of one pipe about 5 in. deep into the butt of another by heavy strokes of a maul. The wheelbarrows used for measurement and for hauling the gravel from the platform to the mixer had a capacity of $2\frac{2}{3}$ cu. ft. each. Usually one sack of cement (the volume of the loose cement in one sack being 1.15 cu. ft.) was mixed with three wheelbarrows of sand-gravel mixture. The proportion of concrete mixture was $\frac{1.15}{3 \cdot 8} = 1:7$. This proportion corresponds quite closely to the proportion required by the specifications, namely, one part of cement, three parts of sand, and six parts of gravel. The experiment made with sieved sand and screened cement showed that 3 cu. ft. of sand and 6 cu. ft. of gravel, being thoroughly mixed, had the volume of a little more than $6\frac{3}{4}$ cu. ft. The wheelbarrows in which the mixed concrete was hauled were of a different type, and their capacity was 2 cubic feet.

During eleven days 8601 cu. ft., or 319 cu. yd., of concrete work was laid. That is, 29 yd. per day in average, including 23% of hand-stone.

The cost data from which the following estimate has been computed, were procured from Mr. Fagg, the manager for the Gold Mountain Company.

Lumber for forms, scaffolding, platform, kitchen, and storehouse, 12,000 bd. ft., at $15 per M, total, $180.

The sand and gravel mixture was included in the cost of labor.

Cement, 984 sacks, at $2 per sack (including delivery), $1968.

Three steel pipes imbedded in the body of the dam; one 15 in., 17 ft. long, at $15; two 9 in. (by 17 ft. long) 34 ft., at $18.

Six hundred feet of 7-in. pipe was taken temporarily from other work and has to be returned. The cost of its delivery was included in the cost of labor.

Bolts, nails, and wire fastening the forms, and for other work, $15.

Total cost of materials, $2196.

The cost of one sack of cement, as shown in the table, is extremely high, because it includes railroad transportation from Sacramento to Quincy, and twenty miles of hauling from Quincy to the Gold Mountain mine. The hauling of 40 sacks of cement from Quincy required a four-horse team, and a team cannot make the trip from Quincy to the mine in less than three days. The cost of a four-horse team is $12.50 per day; therefore the delivery of 40 sacks cost $37.50, or nearly $1 per sack.

THE COST OF LABOR

Two 4-horse teams, $12.50 per day, 12 days	$300
Lease of mixer, $10 per day, 12 days	120
Delivery of mixer and return to Sacramento on the Western Pacific railroad	60
One 6-horse team, from Quincy to gold mine and return, $15 per day, 4 days	60
Machinist, $6 per day, 12 days	72
15 men (cement-men and carpenters), $2.50 per day, 12 days	450
The boarding of 20 men, $1 per day, for 12 days	240
Total cost of labor	$1,302
Total cost of materials and labor	3,398

The total volume of the concrete work placed in the wall was 8601 cu. ft., or 318 cu. yd. Therefore, the average cost of construction was $10.70 per cubic yard.

THE world's production of lead in 1910 was 1,211,411 short tons, and the consumption 1,196,842 tons.

With the Engineers in Japan

On the morning of November 11 the party arrived at Moji and soon reached the Imperial Steel Works at Yawata. The works were gaily decorated, and tea, with light refreshments, was served to the women at the company office while the men went through the plant. This was built about ten years ago along German lines, though an excellent American rolling mill has since been added. The story of the works was told in the *Mining and Scientific Press* of February 18, 1911. It will be sufficient here to note a few of the more striking features. The output is not large, there being only blast furnaces, each with an average capacity of 150 tons of pig per day and a maximum of 200. An additional stack is now being built. Both bessemer and open hearth steel is made, as are plates, wire, bars, rails, structural steel, projectiles, and a wide variety of products. The problem of steel-making in Japan is not unlike that on the Pacific Coast; there is a demand for many different things, but not enough of any one is used to keep a large plant busy. In 1910 the total steel manufactured in Japan, with over 46,000,000 population, was 79,676 metric tons. In addition, 425,758 tons was imported. Private works in Hokkaido, operated by English and Japanese in partnership, and the Sumitomo works at Osaka, furnish local competition to the Imperial Works in certain lines. The latter, however, must make an effort to satisfy, as far as possible, all the national needs in other lines. As a result the plant is unusually complex. There are a great many small plants in the works, and the visitor can see at the same time an unusually large number of distinct processes under way. This makes for interest, but increases cost. The ore used comes from China, Korea, and Japan in about the proportions of 50 to 40 to 10. The Chinese ore is from the Ta-yeh mines, near Hankow, and is of high grade, analyzing up to 64% Fe. The Korean ore is lower, 52 to 54%, and the local ore still leaner. Some 50 to 52% ore is brought from Hokkaido. The coke is made at the works in Semet-Solvay ovens, the coal being 20% Miike, and 80% local washed coal. The Miike coal is strongly coking, the local coal is not, but the mixture gives a satisfactory product at reasonable cost. About 1000 tons of coal per day is used to produce 600 tons of coke. The ratio of pig to coke is 1 to 1.2. As the flux used is magnesian, the slag is not available for making cement, but instead is granulated and made into building brick. In general, the works are well kept and well run. The furnaces and convertors are not driven as fast as is usual in the United States and have therefore a relatively low capacity. The rolling mill, however, was being operated and the quality of the products throughout is excellent. The works were able to show a profit for the first time in 1910, when there was a surplus of $50,000. It should be remembered, though, that the loss on manufacturing in other years was more than balanced by the lower price of steel products, besides which the works accomplish the main purpose, that of giving the Empire an independent source of supply. The works are under the direction of Lieutenant General Baron Yujiro Nakamura, assisted by a large staff of engineers.

THE AMERICAN ENGINEERS IN JAPAN ACCORDING TO W. L. SAUNDERS.

Following the inspection of the plant the local committee visited the steamer, and healths and felicitations were exchanged.

At Moji the party broke up temporarily into smaller sections, a few going to the south of Kyushu to visit the Hasami gold mine, others to see the Miike collieries, and still others to visit points of interest along the line from Shimonoseki to Tokyo. It was at Moji that news was received to the effect that R. W. Raymond and George F. Kunz were among those decorated by the Emperor on the occasion of his birthday. This naturally gave much satisfaction, and the event was duly celebrated.

The Hasami mine is one of the gold mines of Japan that enjoys the benefit of a modern plant. There are 100 Allis-Chalmers 1050-lb. stamps, of which 20 had just been added at the time of the visit. The crushed ore is classified into sand and slime and treated in vats, using Dorr thickeners, a Butters filter, and precipitation in zinc-boxes. The plant is designed to handle 500 tons per day, and the ore is said to assay $7 to $10, the value contained being mainly gold, though there is a little silver. The ore is a breccia in veins crossing Tertiary sediments, and related to intrusives of which some fragments appear in the breccia. There are several veins, of which the one mainly worked will average perhaps 22 ft. wide. At 500 ft. in depth, sulphides become abundant, but it is reported that this does not influence the recovery. The ore-shoot is long and there is seemingly a large tonnage available. One of the difficulties met in operation is the inadequacy of the dumping room, since below the mine are valuable ricefields. Waste must therefore be hauled away by an aerial tram. The mine seems to offer possibilities for large production.

The Miike colliery, which belongs to the Mitsui family, was among the most interesting plants visited by any members of the party. The wealth of detailed information available precludes any adequate condensation, and a description must be postponed for a later special article. The visit will ever remain in memory as one of the pleasantest and most instructive made in Japan.

Moji, where the main party remained, ranks now as the most important coaling station in the Far East. The average yearly export of coal is from three to four million tons. Fifteen years ago the place was a sleepy little seaside village, but development of the important Chiku-Ho coalfield, and the making of the port the northern terminus of the Kyushu railway, has changed all this. With cheap fuel, abundant rail and water transportation, Moji is becoming the centre of an important manufacturing and shipping district. Sugar refineries, portland cement mills, and other plants line the shore of the straits, across which at Shimonoseki may be seen the tea house within which Prince Ito and Li Hung Chang signed the treaty that closed the Sino-Japanese war, and within sound of which the battle of the Japan Sea was fought. The visiting engineers and their ladies were entertained here at dinner in the evening by the Chiku-Ho Coal Miners' Association. The city, which is an important coal-shipping port, had been elaborately decorated for the visit of the Emperor on his way to the autumn maneuvers, and was most beautiful. The dinner was no less satisfactory from any point of view. The address of welcome, delivered by Takichi Aso, president of the Association, is given below. In its tone of friendliness it is characteristic of those delivered wherever the party stopped:

"Ladies and Gentlemen: As president of the Chiku-Ho Coal Mining Association, I thank you sincerely for your kind presence here today. We are highly gratified by your extending your visit to this part of the country. I am sure you will not regret it, for we may assure you without offending our sense of modesty, that northern Kyushu is not behind any other part of the Empire in its industrial progress, and occupies a unique position in regard to coal mining.

"The development of the coal mining industry in northern Kyushu is, indeed, remarkable. In 1886 the whole output of coal did not much exceed three hundred thousand tons, but by 1910 the amount leaped up to the respectable figure of over eight million tons; in other words, an increase of 275% in twenty-five years. Northern Kyushu contributes more than half of the whole production of coal in Japan. Northern Kyushu's pre-eminence as coal producing centre is, indeed, such, that Moji and Wakamatsu are now the premier coal markets of the whole Far East.

"I do not mention these facts in any spirit of local self-glorification. I do so, because our guests hail from that great country which, more than any other Occidental State, has laid us under lasting obligation in connection with the development of our coal-mining industry. It is from the United States, especially from your Institute, that we have received most inspiration and help in the improvement of the method of mining.

"It, therefore, affords us particular pleasure and satisfaction to welcome you, the members of the American Institute of Mining Engineers and their friends. We wish to take this opportunity of thanking you and through you the coal-mining concerns and experts of America for all the suggestions and assistance that have been so freely given us.

"I propose the health of our distinguished guests."

From Moji the engineers went by special train to Kobe, arriving Sunday afternoon. Monday morning was spent seeing the famous castle and other points of interest at Osaka, 'The Chicago of Japan,' followed by an elaborate luncheon tendered by Baron Fujita, head of the great firm that owns, among others, the Kosaka copper mine. It was a matter of much regret that this interesting property, where open-cut as well as underground work is carried on, and where one of the furnaces is 64½ ft. long, could not be visited because of the distance. A few of the engineers remained, after the main party left for San Francisco, in order to see it. At Osaka, among other souvenirs, each member of the party was given a beautiful silver medal struck at the Imperial Mint in commemoration of the visit. In the afternoon the whole party rendezvoused at Suma, the country villa of Baron Sumitomo, head of the firm owning the Besshi and other mines. The broad lawn had been decorated, and, following an exhibition of native methods of fishing in the Inland Sea, on which the garden faces, an elaborate tea was served. Baron Sumitomo expressed his pleasure in welcoming the guests, and asked them to consider the hospitality that had been offered the engineers as but a slight token of the deep appreciation felt by all Japanese of the courtesies that had been extended to visiting Japanese engineers and students in America. He hoped that the same friendly coöperation would continue to prevail. R. W. Hunt replied in one of the brief happy speeches with which he responded so frequently on behalf of the party throughout the trip. After spending the night at Kobe the engineers resumed their journey the next day, reaching Tokyo late in the evening.

Wednesday, November 15, was spent in the capital city, there being numerous private lunching and shopping parties. In the afternoon the guests were taken to a garden party given by the Empress at the East Palace. In their autumn dress the maples of this garden gave a rarely beautiful setting for the royal chrysanthemums, to which the Empress and her suite came for their annual view. After the garden party the engineers were received by the Tokyo Chamber of Commerce, where an elaborate tea was served following an unusually interesting series of addresses. It may be noted in passing that in Japan the Chamber of Commerce is a State institution and its directors are elected by the taxpayers. Incidentally, and characteristic of the unexpectedness of things in Japan, women vote in these elections.

In the evening there was an elaborate theatre party and dinner tendered by Baron Iwasaki of the Mitsu Bishi Co., Baron Mitsui, and Mr. Toranosuke Furukawa. The entire Imperial theatre had been taken for the evening, and visitors' money was worthless at the bar, café, and even the souvenir stands. Three short plays were presented, two classical and one modern. It speaks volumes for the skill of the actors that plays written before Shakespeare died and presented in Japanese, were by their art made to appeal to the Westerners. Certain of the comedy scenes, however, required no interpreter, since, fortunately, "one can play in any language."

Thursday the party went to Nikko, the famed beauty spot about 100 miles from Tokyo. Nikko is at the same time the site of the copper refinery of the Furukawa company, which operates the Ashio mine. This mine was described in the *Mining and Scientific Press*, October 14, by T. T. Read, and no redescription will be attempted here. Certain special features will be discussed in a later article. It may be noted, however, that here, as at Shisaka, Miike, and elsewhere, the visitors found much of technical as well as human interest, and were impressed with the fact that whatever may have been true in the past, Japanese mining engineers have long passed the period of adaptation and are now busy inventing. It was at the Ashio that M. Otagawa, wishing to use a copper converter and having as a guide only the halftone reproduction of a view of the outside of one, proceeded to re-invent and build it. An excellent converter was the result. To that has now been added the Kojima double-settling cone, the Asano method of neutralizing not only the SO_2 but the SO_3 in smelter fume, the Watanabe-Asano method of preventing freezing in blast-furnaces by feeding coal through the tuyeres, the S. Watanabe briquetting machine, an improved casting machine, and a number of other useful devices and methods which caused the visitors to fill their notebooks and ask for blueprints, all of which were freely given. At the refinery a bridge built of copper bars, one day's work, had been erected over a copper-sulphate river, and in a nearby tent an elaborate luncheon was provided. The Furukawa company makes about 1000 tons of copper wire per month, for which purpose 600 tons of copper is produced from its own mines, mainly at Ashio. At the latter, visited by one section of the party, the main street had been decorated with lanterns and flowers for a mile or more, and fireworks announced the coming of the guests. At the company clubhouse in the evening a dinner and an especially enjoyable geisha dance was tendered by the general manager, K. Inouye, and his staff. Saturday morning was spent visiting the mine and mill, while Sunday and Monday were passed at Kamakura, Miyanoshita, Tokyo, and Yokohama by various sections of the party. Tuesday all the members came together at Yokohama and gave a farewell luncheon "to their Japanese friends." Responding to the toast to the Emperor, Baron Shibusawa expressed pleasure at the visit of the engineers and the hope that they had found in the natural beauty of the country, the many things that had been developed in the last half century, and the sincerity of the Japanese welcome, some recompense for the voyage. He insisted that the occasional rumors of war had no basis in the sentiment of the Japanese people, whose feeling for America was rather one of gratitude. Lasting friendships between nations, he said, must rest on personal friendships between individual citizens of the nations, and he was glad to feel that between those present and themselves there was complete understanding. He hoped that the visitors would communicate this to their friends at home and that closer business ties between the two countries might result. Response was made to the toast to the President by Charles Page Bryan, the newly accredited American Ambassador. Following him, J. W. Richards, vice-president of the Institute, spoke, after which W. Watanabe, director of the Engineering College of the Imperial University of Tokyo, referred approvingly to the 'open-door policy' that Japanese mining engineers had always met in America, especially commending James Douglas and R. W. Raymond for their help to foreigners. He regretted that he had been unable to accompany the party through Japan, and wished the visitors *bon voyage*. Kahe Otani, the president of the Yokohama Chamber of Commerce, Thomas Sammons, the American Consul General, and R. W. Raymond followed in turn. As Dr. Raymond's address marked the close of the excursion to Japan, it is given in full below:

"I count it a great privilege to speak for my sisters and brothers of the visiting party of the American Institute of Mining Engineers this final parting word

"You have entertained us in a manner far surpassing our utmost expectations. The abundance of your courtesy has been excelled only by its exquisite grace and artistic ingenuity. At every step you have surprised as well as delighted us. We looked upon you before with admiration and respect; but our admiration has become astonishment, and our respect, personal affection.

"I must be permitted to make special acknowledgment of the favors shown to me during my stay in Tokyo, and particularly of the great honor of the Decoration of the Rising Sun bestowed upon me by His Majesty the Emperor of Japan, and of my presentation to Her Gracious Majesty, the Empress. These high distinctions were accorded to me, as the official notification declares, in recognition of my services to the mining industry of Japan. I will not, in excess of modesty, deny that I have been able, during the last twenty-five or thirty years, to give to Japanese students and engineers in the United States, important help. But my individual services would have had little value, had they not been reinforced by members of the Institute, who cordially responded to my letters of introduction with the open door of knowledge and the open hand of fraternal aid. I wear my honors, therefore, as their representative.

"We wish we could present to you, at this hour, some worthy symbol of our appreciation of all that you have done for us. You have laid upon us the obligation of debt which can never be repaid -which can never be forgotten; and the token of this obligation now offered is only a token.

"The specimen of native, crystallized American gold is a small thing; yet it is, like your reception of us, unique, and therefore priceless. Let it indicate our recognition of the native gold of your generous hearts, which has crystallized for us in forms of delicate beauty and enduring strength.

"I have carried it in my pocket over sea and land 'for luck', but the unbroken good fortune which we have experienced here came from no amulet; and we need no such charm to protect us on our homeward way from disaster or disappointment. We shall be guarded by the memory of a happy dream—no, not a dream, but a real sojourn in Paradise.

"I deliver this token to the Japanese Reception Committee, requesting them to place it in the collection of the Imperial University of Tokyo, with this label: 'Presented by Dr. R. W. Raymond, Secretary Emeritus of the American Institute of Mining Engineers, in recognition of the generous and graceful courtesy extended to the visiting party of members and guests of the Institute through the Empire of Japan.'"

[Thanks by W. Watanabe, after which Dr. Raymond resumed.]

"And now comes the hardest part of all!

"My knowledge of the Japanese tongue has been confined to two words, 'O-hio', for friendly greeting, and 'Banzai', for enthusiastic praise. It is needless to say that these two words have been on my lips and in my heart continually since I landed on these shores. But today I have had to learn another—'Saionara', for farewell—the sad sweet melody of which lingers like the deep tone of a temple bell.

"Saionara! Dear old friends, and new that shall be old!
Saionara, fair Nippon!
O Land of ancient story, long concealed,
In this new age to wondering eyes revealed:
O Land of youth renewed, and flag unfurled,
To greet the banners of a friendly world;
O Land of heroes, strong to do or die,
Yet stronger still for peaceful victory;
O Land of templed hills and shadowy bowers,
Of fruitful fields, and gardens gay with flowers,
Give us thy love, as we have given ours!
Saionara!"

Revised Atomic Weights

The International Committee on Atomic Weights has issued its annual report on the atomic weights to be used in 1912. The committee has investigated researches that have been made on the atomic weights of nitrogen, sulphur, chlorine, iodine, sodium, calcium, mercury, vanadium, tantalum, tellurium, iron, uranium, scandium, neodymium, erbium, argon, and niton, the last previously known as radium emanation. Many of the researches simply confirm existing atomic weights. In the cases of calcium, mercury, vanadium, tantalum, iron, and erbium the researches have been so positive that the committee has deemed it advisable to make changes, which, however, except in the cases of mercury and vanadium, are only slight.

The changes that have been made are based on the following researches. Calcium. From analyses of the chloride and bromide (*Jour. Amer. Chem. Soc.*, 32: 1577, 1910 and 33: 28, 1911), Richards and Honigschmid obtained the figures 40.07 and 40.074, respectively. The figure 40.07 has been adopted. Iron. From analysis of ferrous bromide (*Jour. Amer. Chem. Soc.*, 33: 319, 1911), Baxter, Thorvaldson, and Cobb obtained the figure 55.838, while Baxter and Thorvaldson (the same, p. 337), starting from meteoric iron, found the value to be 55.836. The figure 55.84 has been adopted. Mercury. As suggested as likely in the review of last year's report, Eastley, from further researches on the analysis of chloride (*Jour. Amer. Chem. Soc.*, 32:1117, 1910), confirms his previous conclusion that the atomic weight of mercury was altogether too low. He finds that it should be 200.63, instead of the old figure, 200. The committee has adopted the value 200.6. Vanadium. By heating sodium vanadate in a stream of hydrochloric-acid gas and converting the sodium into chloride (*Jour. Amer. Chem. Soc.*, 32: 1603, 1910), McAdam obtained 51 as the atomic weight of vanadium. This figure has been adopted. Tantalum. By hydrolysis of the penta chloride (*Jour. Amer. Chem. Soc.*, 32: 1127, 1910). Balke has determined the ratio $2TaCl_5 : Ta_2O_5$ and obtained the figure 181.52 as the atomic weight of tantalum. The rounded-off value of 181.5 has been adopted. Erbium. From analysis and synthesis of the sulphate of neoerbium (*Berichte*, 43: 2635, 1910) Hoffmann obtained the figure 167.68 as the atomic weight of erbium. The value of 167.7 has been adopted. Niton. By the aid of a microbalance (*Proc. Roy. Soc.*, A, 84: 536, 1910), Gray and Ramsay have determined the density of the emanation from radium, which they have named niton. Niton, with an atomic value of 222.4, is the only new element to find a place in the table this year.

To recapitulate, then, the new atomic weights adopted by the International Committee are: calcium, 40.07; erbium, 167.7; iron, 55.84; mercury, 200.6; niton, 222.4; tantalum, 181.5; and vanadium, 51.0.

An Improved Rail Clamp for Holding Steam-Shovels in Position

A new rail clamp invented by W. H. Bates, superintendent of steam-shovel repairs at Panama, is described in *The Canal Record*. After a six months' trial, 350 of these clamps have been put in service on the canal work. The function of this clamp is to act as a stop when a shovel is moving forward, to prevent its running off the end of the track; also to 'block' the truck wheels securely in place when the shovel is working.

The clamp used heretofore was attached to the rail by means of a key driven under the base of the rail, consequently it was necessary to place the clamp between ties. When the track is in mud and water up to the rails, the annoyance and delay incident to attaching the clamp are considerable; furthermore, the ties often interfere with placing the clamp where desired. The new clamp is fastened to the rail by means of a tapered key of steel passing crosswise over the rail and thus permits the clamp to be set directly over a tie, or any place desired. The key being above the rail, avoids the mud and water. The principle on which the clamp works is similar to that of a pair of ice tongs. It consists of two steel castings which form the hooks and body, as well as a convenient handle. These castings are fastened together by means of a heavy rivet which acts as a hinge-pin. The hooks bear on the under side of the rail-head when the wedge is driven above the rail, and below the hinge-pin; thus giving a secure grip on the rail. The cost of the new clamp is considerably less than that of the old style.

Mining in Panama

The mining regions of Panama so far developed are in the provinces of Darien and Veraguas, the development to date being mainly in the former province. Thirteen new claims were denounced in 1910 throughout the Republic. There is urgent need of revision of the mining laws, which permit the denouncement of claims under conditions which do not insure their working. Either a tax should be put on such property sufficient to prevent its being held for purely speculative purposes, or some requirement as to an amount of work or investment necessary to hold the title should be adopted. Of 125 mines held under valid concessions granted since the year 1904, very few are being worked on any scale, and some 40 have been abandoned altogether.

The Darien Gold Mining Co. employs about 400 natives and some 20 white foremen, superintendents, and skilled laborers. In this district is the San Antonio gold mine, near the banks of the river Congo, an affluent of the river Tuira, and the forest in that locality abounds with mahogany, cocobolo, cedar, and many other woods.

A company recently formed under the laws of Arizona, with capital of $3,000,000, is to operate gold and copper properties in the province of Los Santos, owning eight gold and three copper mines in the district of Las Minas, covering an area of some 4000 acres. Machinery has been purchased and shipped for a mill to treat 25 tons of ore per day. One of the mines, El Gallo, has gold ore estimated at 200,000 tons, running from $2.50 to $4.13 per ton. The copper mines, which are to receive preferential attention, show ore running from 7½ to 30% copper, 7 oz. silver, and $3 to $6 gold per ton. J. Gabriel Duque, managing director of the Panama *Star and Herald*, is president of the company, with other well known names figuring on the board.

On the river Marroquin, in the province of Los Santos, and in the vicinity of the Miopos mountains, there is a gold mine which has not been worked for a long time. Near the headwaters of the Rio Cocle, in the province of the same name, there is a mine called Santa Catalina, which, judging from the implements and tools left, must have been worked by the Spaniards, and the mineral now taken out assays well.

Many gold mines were formerly worked along the mountain range in the vicinity of the Cocle, Belen, and Indian rivers, in the Cocle province, the most noted being the San Antonio mine, which once had an output of about $40,000 gold, but all were abandoned before the advent of modern machinery, because of the high cost of working.

The mines and gold croppings within the territory of the Isthmus have always enjoyed renown, owing to their richness, and the first Spanish settlers called this territory Castillo de Oro (Gold Castle). The Cana mines were also called Potosí to qualify the abundance and richness of the gold ores taken out. After being abandoned for many years, the mines of Cana are now worked by an English company, which reopened the road to the mines and for upward of twenty years these mines have yielded a fair output from their rich lodes.—*Peru Today.*

San Francisco imported $199,001 and exported $4,796,550 gold coin and bullion, and imported $135,299 and exported $794,912 silver coin and bullion in seven months of this year.

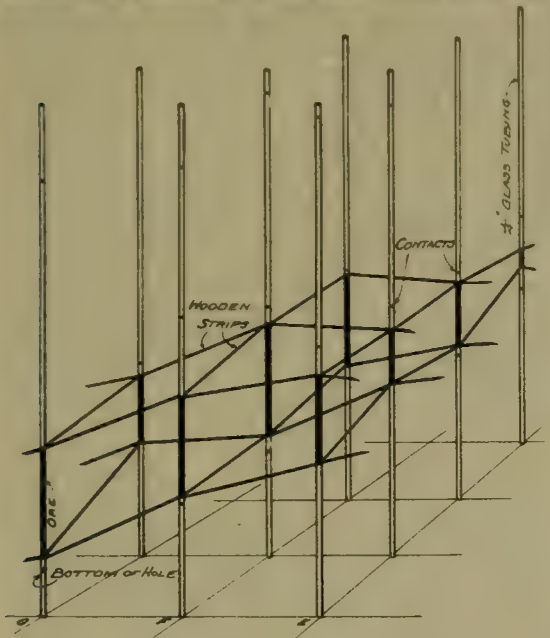
The National Railways of Mexico have recently borrowed through New York bankers $13,000,000 with which to retire an old London loan and to build new mileage.

A Satisfactory Mine Model

By W. St. J. Miller

The following description of a mine model constructed by the engineering department of the Live Oak mine, Miami, Arizona, after several attempts to design and construct the most satisfactory model showing the shape and extent of an orebody developed by churn-drilling, may be of interest. First of all it must be understood that this is not a working mine model, but is made from data obtained by churn-drilling only. The drill-holes were put down at the intersection of coordinates 200 ft. apart, there being some 86 holes drilled and in process of drilling at present.

A map of the property, showing claims and underground workings, was mounted on a table made with a top 2¾ in. thick, resting securely on trestles, and 1¼ in. holes, 1 in. deep, were drilled at every drill-hole location. To insure the verticality of these holes a block of wood about 4 in. each way was nailed to a flat base-plate about a foot long with a ¼-in. hole down the centre to guide the bit. The drill-holes are represented by ¼-in. specially selected glass tubing 30 in. long. The elevations at top and bottom of the holes and at the contacts are marked with a black ring, and the geological formations passed through painted in various colors. Tube oil-paints were found to give by far the best effect for this work. A little 'Japan drier' should be added. The commercial grade of ore is painted a solid black. After all the painting was finished and dried, the tubes were placed in their respective holes on the table. A very thin strip of lead foil was wrapped around the bottom of the tube, forced into the hole, and snugly calked with a tool similar to that used by dentists. Plumb-bobs were hung on the walls as a guide to keep the tubes absolutely vertical while calking.



LIVE OAK MINE MODEL.

As the illustration shows, the top and bottom of the orebody was outlined with thin black strips of wood from hole to hole. At first it was difficult to find some suitable material for these strips, and eventually the idea of the ordinary Chinese bamboo 'punks' was thought of, so the left-overs from Fourth of July were bought up. After being scraped clean and painted, these answered the purpose admirably. On the drill-holes at top and bottom of the ore, small rubber bands cut from tubing were placed, on which to rest the strips, the latter being glued together. Each drill-hole has a tag fastened to the top of the glass tube on which its number is printed. The scale used is 50 ft. to the inch, both vertically on the drill-holes and horizontally on the table. The datum plane of the table is 2650 ft., and the top of the glass tubes 4100 ft. above sea level, representing, respectively, the assumed bottom of the deepest hole likely to be drilled and the highest surface elevation on this property.

This is, I believe, an original method of constructing a model showing both the drill-holes and the orebody, and should prove useful in planning a system for future mining operations, also for the quick selection of shaft and mill-sites, as the thickness and area of the ore at any particular place is at once visible. The top and bottom contours of the orebody show up distinctly in this model, as do also the different thicknesses of the capping, and the various formations drilled through, although the depths of these latter are not joined together with strips on account of the confusion this would cause. The Live Oak orebody is of the so-called low-grade 'porphyry' class, and its shape, comparatively slight dip, and the large area over which it extends adapt it especially to this style of model.

Drilling Under Difficulties

The accompanying photograph shows a core-drill at work at the El Refugio mine, about 15 miles from Salinas, State of San Luis Potosi, in a peculiarly difficult situation. The district, like many others in Mexico, has been subject to great disturbance. Large faults have occurred in many districts, distorting the veins and sometimes occasioning much difficulty in discovering in depth the ore proved in the upper levels. The drill is shown in position on the side of a deep ravine, the result of a great vertical fault. In this case the walls stand perpendicularly and are two or three feet apart.

The dip of the strata is 45°E., so in order to cut the strata at right angles to the inclination, thus securing a core of the greatest possible number of layers, with the shortest possible length of hole, the drill is tilted at an angle of 45° to the west. This hole was drilled to a depth of 400 ft. The drill, a Sullivan Class E, is operated by steam, from a portable boiler. The transportation and installation of this boiler involved no mean engineering difficulties, as the mountain passes are very rugged and steep, and unceasing caution was required to prevent the outfit from capsizing into one of the deep gulches along the trail, and during the last 500 yd. of this journey the boiler had to be carried on skids.—*Mine and Quarry.*

Discussion

Readers of the Mining and Scientific Press are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Foreign Words in English Writing

The Editor:

Sir—When will the average Anglo-Saxon writer cease to mutilate the Spanish language? If he is not a good Spanish scholar, why not consult a dictionary before writing a word erroneously? Some correspondents seem to take a delight in going out of the way to use Spanish words, to show the extent to which they are acquainted with the language and impressing the profane, and then do not get them right, even where they are in constant use. Why not use the English word and be done with it? These thoughts are suggested by reading articles that have appeared from time to time in the *Mining and Scientific Press*. Nothing destroys the effect of an otherwise well written article so much as to see ordinary Spanish words erroneously written. It conveys the impression of a certain carelessness which detracts from the rest of the subject-matter. Your publication is doing good work in pointing out the necessity of employing clear and specific language in dealing with technical subjects. It is not too much to ask that where foreign words are brought in, especially where they are unnecessarily made use of to the exclusion of the English equivalent, care should be taken to see they are correctly written.

Anglo-Mexican.

Conservation of Investments in Gold Mines

The Editor:

Sir—In your issue of December 9, Morton Webber, in 'Conservation of Investments in Gold Mines,' advocates that companies set aside certain portions of the net proceeds, even to the exclusion of dividends, until there is in the treasury a sum sufficient to repay the par value of the shares. Mr. Webber contends that the conserving of dividends that otherwise might possibly be spent by the shareholder is really "a blessing in disguise." Certainly one cannot eat his cake and have it, too. The average purchaser of mining shares is presumed to have some intelligence, though ofttimes he exhibits a great lack of any, and, in the latter case, the assumption of a, so to speak, paternal control of his financial welfare, handling any profits that might accrue to his interests, might well be to his best advantage. However, the law already makes provision for the appointment of guardians for the care of those who are mentally incompetent, and it is not the special province of a mining directorate to usurp this power. Possibly the appointment of an alienist board to pass upon all applicants for an allotment of shares might solve this question. The retaining by the management of any profits in excess of a sufficient and advisable reserve, while pleasing to those in actual control, is hardly a policy that will appeal to the average shareholder. Aside from such reserve, I believe that any balance of profit should be distributed to the shareholder, to do with as he pleases. If he spends it riotously, or hoards it miserly, it is his business.

The tendency in these theoretical discussions on mining is to assume a hypothetical set of facts and to draw conclusions therefrom. It is an easy step from this to the assumption that in actual practice the future of the property can clearly be foreseen, and that in the initial stages of the career of a mine, accurate estimates can be made providing for amortization of capital and a regular rate of dividend. As a matter of fact, the sane investor in mining does not ask for this. He knows he is engaging in a speculation, and what he really asks is a frank statement of the facts as they are ascertained and an honest and capable administration of the property. Mr. Webber asks us to repose a blind confidence in the integrity of the directors, permitting them to conserve our investment instead of allowing the investor to take his profit as it accumulates. If anything goes wrong, it is found out at the wind-up of the corporation, when it is too late to act. A more rational substitute for Mr. Webber's plan would be a comprehensive corporation act providing that the directors disclose to the shareholders, at stated periods, the financial position of the company and the physical conditions of its properties, also that from time to time independent engineers be engaged to check these data. It is unnecessary to go into details of the necessary characteristics of a report on a mining property, as the Mining and Metallurgical Society has already done this, and also suggested by whom it should be made.

One of the purposes in the organization of stock companies is to provide that the interests of the various shareholders be allotted in such a way as to be liquid; that is, the owner is at any time able to go into the open market and realize on his shares. The issuance of shares at far less than the par value is often justified by the prospective stage of the property and the highly speculative risk. The shares first issued by many of the Rand companies were issued at par and the money used to prospect the property. When sufficient ore was assured to yield a reasonably certain profit, the remaining shares were issued at prices far in excess of par in order to supply equipment. Those receiving the first allotment are engaging in a highly speculative investment, those receiving the second allotment are engaging in a more conservative investment.

In this country it is often customary to issue shares at a price far below par, because of the speculative nature of the investment, but really the case is somewhat parallel to that of the Rand companies.

The purchaser knows (or should know) that he is taking a highly speculative chance, and there is no reason why he should wait until the shares reach par before taking—if the opportunity offers—a profit on his investment.

Of course, for 'wild-cats' unaccompanied by reports of competent mining engineers, organized and floated by irresponsible promoters, even a moment's consideration is unnecessary. In regard to such cases the law should make provision to compel promoters to publish all contracts, and preliminary profits and reports, and should hold them responsible for all statements issued in the prospectus, in a manner similar to that provided for in the British Companies Act.

Charles Janin.

San Francisco, December 11.

Determination of Copper, Nickel, and Cobalt

Take 2 to 5 gm. of pyrrhotite, 0.5 to 2.5 gm. of nickel matte, and 10 to 20 gm. of slags. After dissolving in concentrated HNO_3, concentrated H_2SO_4 is added and the solution evaporated till fumes of SO_3 are evolved; water is added and the evaporation repeated. The residue is filtered off and the iron precipitated three times with ammonia, after which it is titrated. Sulphuric acid is added to the filtrate from the $Fe(OH)_3$, and after reducing the volume to 150 c.c. the copper is determined electrolytically. Then the solution is neutralized with ammonia and 20 c.c. of the concentrated reagent added in excess, and then the cobalt and nickel are determined electrolytically. The nickel and cobalt are dissolved by boiling with 40 c.c. of concentrated nitric acid, the solution evaporated to dryness, 1 c.c. concentrated nitric acid added, and the solution again evaporated on the water bath to remove all HNO_3. This residue is treated with a few drops of diluted HCl, dissolved in 150 c.c. water and the nickel precipitated with 20 c.c. of 1% dimethylglyoxime in alcohol. The precipitate is filtered on a Gooch crucible, washed six times with hot water, dried 2 hours, and weighed; it contains 20.3% nickel.—H. Pedersen in *Metallurgie*.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A PERCH of masonry should actually contain $24\frac{3}{4}$ cu. ft., being $16\frac{1}{2}$ by $1\frac{1}{2}$ by 1 ft. But it is frequently taken at 25 cu. ft. and sometimes at 22 cu. ft. Fortunately it is gradually falling into disuse.

MINIUM is the naturally occurring red oxide of lead, containing 90.6% Pb. It occurs as a vivid red powder, or loosely compacted mass of a dull or greasy lustre. It is of no importance as an ore of lead.

RETAINING walls should be sloped backward on the inside for 3 or 4 ft. below the top, when constructed where deep freezing occurs. The surfaces should be made quite smooth, to loosen the hold of the frost and prevent displacement.

MARBLE, as well as other building stone, may be located as placer claims upon surveyed or unsurveyed public land, but not upon school or State lands. Upon surveyed land building stone may also be located under the provisions of the Timber and Stone Act, as well as by placer location.

WROUGHT-IRON pipes have the advantage of lightness, toughness, and pliability, as compared with those made of cast iron. The lightness makes them cheaper per foot, though costing more per ton. As they are made longer than cast-iron pipes (15 to 18 ft. instead of 12) fewer joints are required per mile.

GOLD is extensively used in the arts, the annual consumption for gilding and electroplating, decorating pottery, bookbinding, sign manufacturing, and a host of other uses is great, and the amount lost in such forms annually is not inconsiderable. Coins and jewelry are its principal uses. It was estimated some years ago that 100 oz. daily was consumed in England in the form of gold leaf.

SPATHIC ore is the old name for siderite, the carbonate of iron (48.3% Fe). It occurs in granular masses of a gray or brown color, and often resembles dolomite, from which it may be distinguished by its greater weight and by becoming magnetic on heating. Some varieties resemble sphalerite. It was formerly important as an ore of iron, but, in America, has largely lost its place, furnishing only about 1% of the total iron ore.

WHEN testing electric fuses they should always be placed in such a position that if one of them should happen to detonate accidentally, no one will be injured. Placing them around the corner of a stone wall is an easy and safe way, or, if there be but a few of them, they can be buried under a foot of dry sand. If there are many, so that the total amount to fulminate is considerable, the particles of sand themselves would become projectiles capable of injuring any one nearby.

MORE than $21,000,000 worth of sand and gravel was dug for sale in the United States in 1910. This is a figure not many million dollars removed from the present annual production of silver. According to a report by Ernest F. Burchard, just issued by the United States Geological Survey, the production of glass sand, other sand, and gravel in 1910, was 69,410,436 short tons, valued at $21,037,630, against 59,565,552 short tons, valued at $18,336,990, for 1909.

ELEVATION of the outer rail on curves is theoretically equal to the square of the velocity in feet per second multiplied by the radius in inches divided by the radius of the curve in feet multiplied by 32.2. The product is expressed in inches. Experience shows that ½ in. for each degree of deflection angle (100 ft. chords) does very well for standard gauge up to 40 mi. per hour. At 60 mi. per hour use 1 in. per degree. In approaching the curve raise the rail at the rate of 1 inch in 60 or 80 feet.

TIRE punctures may be sealed by the use of a mixture made of 4 oz. of pumice (pulverized), 2 oz. of dextrin, and 10 oz. of water. Force the paste into the tube through the valve, after the insides have been withdrawn, by means of a small metal filler. It is claimed that this paste will close a good sized hole and enable the machine to proceed for many miles without detaching the tire; in fact, in one case a tire so repaired is said to have remained fully inflated for a week. When the tube is patched care should be used to see that all of the paste is removed from it.

SALT DEPOSITS and salt springs are covered by an act of Congress, which provides that all unoccupied public lands of the United States containing salt springs, or deposits of salt in any form, and chiefly valuable therefor, are hereby declared to be subject to location and purchase under the provisions of the law relating to placer-mining claims; provided, that the same person shall not locate or enter more than one claim hereunder. This act is operative in all the public lands of the United States, and not in the mining-law States alone. It is only by the production of salt through the usual processes that a saline spring or deposit becomes subject to placer location, and the use of a salt spring as a bathing resort instead does not tend to validate a placer location.

TOWNSITES upon public lands of a mineral character are provided for by the statutes. Because of somewhat conflicting acts and decisions, and the variety of conditions met, the law is not entirely clear, but the following are the general principles. The law contemplates giving titles to lots of land occupied for business or residence purposes, but with the right to mine paramount to other occupation or use of the land. Consequently, the law purposes that mining claims valid by reason of a mineral discovery prior to occupation of the land for townsite purposes, are to be reserved from townsite patent; likewise, but to a lesser extent, a valid location made after townsite occupation, but prior to the issuance of townsite patent, will be protected. The status of locations made after issuing of townsite patent and upon ground known to be valuable for mineral before the issuance of patent is more doubtful, but generally they can be sustained and perfected to mineral patent. Locations made and based on a mineral discovery made after the issuing of townsite patent and upon ground not known as mineral ground in a convincing way at time of issuing such patent, cannot be sustained.

OIL-MIXED concrete will commonly be most useful in the form of an application of the material over structures built of ordinary concrete, and to act as a waterproofing material. It is also worthy of note that many colloids will emulsify mineral oils in the same way as portland cement. At the Second International Road Congress, held in Brussels in 1910, a material, known as sand-clay asphalt, was exploited by Mr. Tardres, Engineer of Bridges and Roads at Algiers, some of it being laid on the exhibition grounds as a road surface. It is produced, according to the inventor, by mixing 12 parts of clay with a sufficient quantity of water (about 2 to 6 parts), and adding, while mixing, 12 parts of tar and 100 parts of hard sand. The clay paste emulsified the bituminous material with the same ease as the portland cement paste emulsifies the oil, and it was eventually found that the clay could be replaced by any other colloid matter mixed with water, such as dextrin. Such a mixture forms a plastic mass, and can be readily spread or floated into place. It dries out rather slowly, but eventually becomes quite hard. The inventor claimed that it could be used economically for binding together broken-stone roads, for walks, for cellars and stables, and for similar purposes.

Special Correspondence

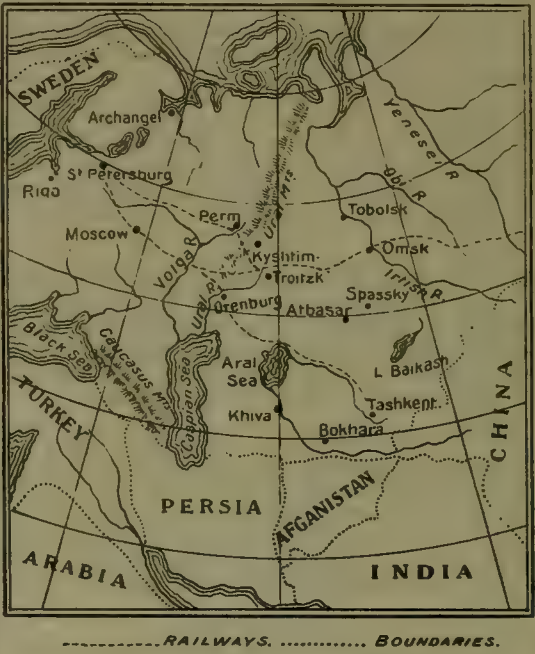
LONDON

'TITTLEBATIAN THEORY' FINDS COUNTERPART IN TRANSVAAL. —TOMBOY'S PROSPEROUS CONDITION INTERESTS LONDON.—BAD WEATHER DELAYS ENLARGEMENT OF CAUCASUS COPPER CO.'S CONCENTRATOR.—MESSRS. WEISS AND ELLIOTT OF CALIFORNIA ON ANCOBRA COMPANY'S STAFF.

A scientific event of similar importance to Mr. Pickwick's and Jonathan Oldbuck's antiquarian discoveries has recently engaged the attention of the geologists and petrographers in South Africa. Some months ago the diamond sorters at the Dutoitspan mine, belonging to the De Beers company, found a new mineral substance among the products of the pulsators, and after due deliberation forwarded specimens of it to the Cape Town University for determination by the mineralogical experts. On analysis the mineral was found to contain 71.3% iron, 20.03% silica, and 8.41% carbon. Its composition and appearance suggested an igneous origin, and its presence in the diamondiferous rock was a source of great delight to the scientists, who hoped that it would afford some argument or information to help in the discussion of the genesis of the diamond. A practically-minded man, however, suggested that the substance looked remarkably like one of the residual products left in the manufacture of acetylene, so a comparison was made with lumps and pellets extracted from the plant used for making this gas in the University laboratories. The physical characteristics, such as hardness, color, fracture, etc., were found to be similar. Chemical examination showed that the substance varied in composition from iron carbide attacked by dilute acids, to iron silico-carbide attacked by hydrofluoric but not by hydrochloric or sulphuric acid. Inquiry at the De Beers showed that acetylene had been manufactured and used at the mines for several years. The conclusion was therefore inevitable that the substance was not a constituent of the diamondiferous rock, but had accidentally found access to the workings. All this goes to show that there are many things in a mine in addition to the mineral for which search is being made, just in the same way as there are, in the words of the song about the seaside, "many things there besides the fresh air."

The Tomboy company, operating in Savage basin above Telluride, Colorado, has been one of the most interesting English ventures in the United States, though the magnitude of its operations has been somewhat eclipsed by the doings of its neighbor over the divide in Imogene basin, the celebrated Camp Bird. The company was formed by the Exploration Company in 1899 to acquire the Tomboy group, and in 1903, as the deposit showed unsatisfactory signs, the Argentine group lower down was purchased. The latter is still doing well, and the ore reserves are well maintained, but it has been deemed prudent to keep an eye open for other investments. About a year ago, the Exploration Company had a chance of purchasing the property of the Revenue Tunnel Company, whose mill is farther north over the divide near Sneffels, and the offer was made to the Tomboy. The directors, however, considered it too big an undertaking, and decided, on questions relating to transport, to confine their future operations to properties on their side of the divide. Subsequently a second proposition was made to sell that part of the Revenue Tunnel property on the Tomboy side of the divide, and accordingly negotiations were reopened. Eventually, in July last, it was decided to purchase this group of claims for £80,000 cash, of which £50,000 was paid from reserve fund and the remainder borrowed from the Exploration Company. This group of claims had never been actively mined, though a good deal of development work had been done, because the cost of tramming to the Revenue mill was considerable. The Ophir adit gives access to the workings from the Savage basin side, so that the ore can be easily delivered to the Tomboy mill. A tramway has been built for this purpose, and should be at work by now. The ore is of similar characteristics to that of the Argentine, and is, indeed, contained in a continuation of the same lode. Its content in gold is about $9 per ton. It seems, therefore, as if the Tomboy company had obtained a new lease of life for the second time.

From time to time I have mentioned the case of the Caucasus Copper Co., Ltd., that unfortunate Anglo-American venture in the south of Russia. Information about the property is scarce and publicity is not courted. The company was formed eleven years ago. The ore is plentiful, but difficult to concentrate, and its beneficiation has given a great deal of trouble. At first, direct smelting was tried, but had to be abandoned, as too much flux was required. Then magnetic separation was given a chance, with equally disappointing results. Finally, three years ago, James Colquhoun, who used to be manager of the Arizona Copper Co., was asked to join the board, and to advise as to treatment. Under his direction, water concentration has been tried once more, and sufficiently good results have been obtained. The plant can treat 500 tons per day, and the smelter capacity is 200 tons of copper per month. The concentration plant is to be increased so as to bring the daily amount of ore to 750 tons. This scheme would have been completed before now, but for the severity of the weather during last winter, when snowstorms and landslides cut off communications and wrecked the pipe-line through which the oil-fuel is delivered to the mine and smelter. The yearly production of copper is now nearly 2000 tons, having increased 100% during the past three years, but it is still 500 tons less than should be possible with the present unextended concentration plant. Unfortunately, the finances have not improved and the indebtedness has increased during the past year by over £100,000. The sums of money involved are enormous; the capital of the company is £500,000, and there are £635,600 debentures, £534,900 loans, and £42,740 accrued interest on debentures and loans. A number of high-class mercantile firms in London are financially interested, and the American interest is represented by the J. P. Morgan group. W. R. Van Liew, late of Montana, is now general manager, having previously been chief metallurgist.



MAP OF CENTRAL RUSSIA.

An English gold-dredging venture that will be of interest to Americans is the Ancobra Exploration & Dredging Co., which operates in West Africa; the reason for the American interest being that S. V. Weiss, of California, is in charge of operations, while Mr. Elliott, the expert driller, was one of the Hammon staff. In early days the operations were not successful, and it is Mr. Weiss, who has put things on a more satisfactory basis. The rights include the bed of the Ancobra river from Prestea to the sea, a distance of 70 miles, and also some adjoining flats. There are three small dredges at work, and a fourth has just been scrapped. Recently the yield of gold from the river bed has improved, and during the first week in November the three dredges produced 230 oz. gold. A more important feature of the work done by Mr. Weiss is the discovery that the flats containing the old river bed are more profitable to work than the present bed. Not only is the deposit richer, but its content can be more exactly ascertained. In addition, it will be easier to work because the vegetation and floods will not interfere so much. Mr. Elliott is now engaged in drilling these flats, and if the results come up to expectations a new dredge capable of handling 65,000 cu. yd. per month will be built.

TORONTO, CANADA

Railroad for Elk Lake District.—Winter Road Will Make Cripple Creek Mines Accessible.—Placer Activities.—Porcupine and Cobalt Notes.

The Ontario Government, in view, no doubt, of the general elections which take place next week, has at last proved responsive to the appeals of the mining men interested in the Elk Lake and Gowganda regions, and has announced its intention of building a branch of the Temiskaming & Northern Ontario railway into the Elk Lake district. The branch will be about thirty miles long and will probably be a continuation of the short line already constructed to Charlton. It is stated that the work is to be proceeded with as early as possible in the spring. This should enable a number of mines, which it was found impossible to develop profitably on account of transportation difficulties and high freights, to resume operations. A winter road is also to be constructed from Timmins Landing on the Mattagami river into the Cripple Creek country to the west. This will open up that section, which has been much retarded owing to its inaccessibility. It is stated that recently a number of options taken on properties there and in Bristol township have been dropped. The latest rush of prospectors to new territory is to the Grassy River, or Kapiskong, region, lying to the south of the Porcupine district. The Grassy river is a tributary of the Mattagami and runs from the chain of lakes known as the Kapiskong, through the townships of Musgrove, Fripp, Price, and Ogden. It is asserted to be a placer area, and a large number of placer claims have already been taken up in the bed of the river and Kapiskong lake. For over three months men have been in the district washing out sands, but it is only quite recently that it attracted prospectors in any considerable number.

Good news from Porcupine district does not seem to have much effect on the stock market, where the general lack of interest, which has prevailed for some time, has been intensified by the dullness which usually sets in in advance of the holiday season. At the Pearl Lake the diamond-drills have reached the lowest depth attained in the district, 1200 ft., with satisfactory results. Assays of six samples taken out between 1162 and 1182 ft. give gold contents ranging between 40c. and $20, and some sludge samples taken between 1170 and 1200 ft. run from $3.60 to $8.40. The McIntyre has found rich ore on the 200-ft. level in a crosscut driven in 35 ft. from No. 1 shaft. The Standard has obtained good results from diamond-drilling, and the management has decided to obtain a 12-drill electrically-driven compressor and equipment. Its camp buildings are almost completed. The Martin location lying to the south of the Dome, lately owned by D. K. Martin and A. J. Young, has been taken over by the Martin Porcupine Mines, Ltd., capitalized at $2,000,000, and will be actively developed. At the American Goldfields, where a 2-ft. vein has been traced for 200 ft., two diamond-drills will be put to work immediately. The machinery of the Little Pet, comprising a 6 drill compressor plant and two boilers, is being erected. The main shaft near the west line is down 45 ft. and the vein has widened and carries free gold. A shaft is being put down on the Pike Lake in the Swastika district, where rich ore was found a little below the surface. The illustration below shows the famous 'golden stairway' recently uncovered by trenching at the Dome mine. The gold content is so high as to give the vein the appearance of a metallic band.

Heavy shipments are being made from Cobalt and bid fair to continue to the close of the year. The La Rose is getting rich ore from the Lawson property, where six tons taken from the new shoot on vein No. 8 is stated to average 9100 oz. per ton. The Kerr Lake is sending out no more ore than is absolutely necessary to enable it to pay dividends, keeping back its output until the tramway to the Nova Scotia is completed and the ore can be shipped in the form of bullion. The Trethewey mill is treating an average of 100 tons per day, which yields about 2000 oz. of silver.

'GOLDEN STAIRWAY,' DOME MINE.

Some important new orebodies have recently been opened up. Charles O'Connell, the manager, estimates that there is now developed underground a three years' supply of milling ore, in addition to a year's supply on the dump. The company reports its financial position, November 10, as $104,695 in cash in bank, due from smelters and value of ore in hand. The net production of the Nipissing during November was $225,907, and the month's shipments totalled $248,980, of which $99,407 was ore and $158,573 bullion. Sir Henry Pellatt, of Toronto, has taken a 3 months' option on the Dominion Silver, North Cobalt, where operations will at once be begun under Mr. Gordon, manager of the Cobalt Lake. A fatal accident, from a very common cause, occurred at the Buffalo, December 6. The drill struck a hole containing an unexploded charge, with the result that one man was killed and three injured. The Canadian Gowganda is shipping a carload of high-grade ore amounting to 50,000 lb. by teaming it to the railway at Charlton. The Powerful, situated between Elk Lake and Gowganda, has found two rich veins in drifting at the 115-ft. level. It has shipped 2 tons of high-grade ore.

BUTTE, MONTANA

Appointment of C. F. Kelley as Vice-President of Anaconda Is Praised.—Tuolumne Surface Plant to Be Ready Shortly.—Other Notes.

The selection of C. F. Kelley, chief counsel of the Amalgamated Copper Co., for vice-president and director of the Anaconda Copper M. Co. in succession to F. P. Addicks, is generally regarded as an unusually wise choice. Although born in Nevada, Mr. Kelley was brought to this city by his parents when an infant and was raised, educated, and achieved his fame as a lawyer and a man of affairs here.

The High Ore mine will not be placed in commission for a couple of weeks, or possibly more, as the shaft repairs are not completed. The fact that the other mines are supplying all the ore required does not make it necessary to hurry the repair work, and when the mine does start up again it will be in first-class condition. The equipping of the engine with the new cylinders for operation by comair have been completed.

The official announcement that the Anaconda Copper M. Co. had secured control of the Southern Cross mine in the Georgetown district and had decided to extend the Butte, Anaconda & Pacific railroad into that district for a distance of about twenty-two miles, did not come as much of a surprise to the people of this district as it has been known that the company has had experts making an examination of the property and having the ore tested for the past several months.

Inside of three weeks the new surface plant of the Tuolumne company will be in operation unless something unforseen occurs to delay the work. By the first of the year the company will be in a position to increase its output and advance with more vigor the development work which has been going on for some time. The station on the 1800-ft. level has been completed and the sinking of the shaft to a depth of 2000 ft. has been resumed.

While negotiations between W. A. Clark and the Butte & Superior company for a merger of interests in the handling of the zinc ores of the two interests were broken off two weeks ago, among persons close to the company and to Mr. Clark there is a strong belief that it will not be long before the parties will come together again and an agreement will be reached.

The official figures of the production of the mines in this district for the past month do not differ materially from those of October, nor will there be any material difference in the production this month as compared with several previous months. It is intended to keep the output around 21,300,000 lb. until such time as the market conditions fully justify an increase. If the surplus continues to decrease and the price continues to increase, it will not be many months before the mines of the district bring the production once more back to the figures maintained before the 15% curtailment went into effect.

Efforts to learn something concerning the object of F. Augustus Heinze in redeeming the Basin Reduction Works property so far have failed. The State Savings Bank officials who had possession of the works through a claim for money loaned, will not say anything beyond the fact that the money to redeem the property was put up by interests connected with Mr. Heinze and that it is now again in the name of the La France company, an organization controlled by him. There is an impression that the money was advanced by W. A. Clark, but, for reasons best known to himself, he does not want the fact known that he is going to take over the works for some time to come, in the hope that he may reach an agreement with the Butte & Superior company.

The new dust-chamber which has been under construction by the East Butte company for the past few months will be completed in about three weeks. The slag walls are nearing completion and in the course of a week the steel roof will be placed in position. Over this will be poured a thin coating of slag in order that the gases may not escape but be carried to the stack. The stack is well under way. It is of sheet steel, 25 ft. diam. at the base and 15 ft. diam. at the top, while it will be 150 ft. high from the base, giving a total height of about 175 ft. The next important improvement will be the building of another blast-furnace. The material is all on hand and it is intended to have it ready for operation in the spring. This additional blast-furnace will increase the capacity of the smelter about 750 tons per day.

The movement started a short time ago by the business men to offset the movement in the East against the silver industry is making some headway, and replies have been received from Chambers of Commerce and various commercial bodies on the coast offering assistance to create a greater demand for the white metal. A formal protest against the refusal of the Government to pay the express charges on its silver to the West is being drawn up, and this will be forwarded to the President, Senators, and Congressmen with a demand that immediate action be taken to grant the relief sought. It is contended that the Government can well afford to pay the charges demanded and still make a profit and that by so doing it would be giving a great impetus to a Western industry. In Montana alone there are a hundred silver mines which could be operated to advantage with a little encouragement in this direction.

NEW YORK

Finlay Reiterates Views.—Arizona Copper Merger Centre of Interest.—Copper Producers Report Analyzed.—China and India Influencing Silver Market.—General Notes.

J. R. Finlay, whose work for the Michigan State Board of Equalization created such a storm of criticism in Boston, appears to be inclined to stand to his guns in his position on mining stocks. Speaking this week before the Engineering Society of New York, he said, in part: "It is perfectly evident that the copper shares are too high. The railroad dividends are a real profit on a stable investment. The mining dividends are a return of capital as well as interest. The railroads are a better property year by year; the copper mines are sure to play out.

"The function of science in prolonging the life of the mining business really lies in widening the field in which fresh deposits can be found.

"It would be utterly impossible for any sane engineer to make a serious report on the valuation of copper mines which would not be disappointing to the average stockholder.

"It is generally supposed in this country that gold mining is a much more risky and generally less productive venture than copper mining. This idea has some foundation so far as the United States is concerned, but as a general proposition it is a great mistake.

"It is preposterous to buy mining shares at a price that will give you a bare interest when every unknown factor turns out favorably. You should pay only a price that will yield a big profit, if all works well, for such would be only a fair compensation for taking the risk of loss if the unknown factors do not turn out well. For these reasons, I think it is generally conceded that a mining stock does not look interesting at all unless it will pay 10%. If you would reject all that do not pay that amount and investigate those which pay more, and do not buy any unless you know something about them, you will stand some chance of making money.

"I do not wish to be understood as being a pessimist on the mining business. My sole point is that the public is led in too many cases to pay extravagant prices for good profitable mines. The very copper mines that I have spoken of as selling too high are all bonanzas. They pay dividends equal to 30 or 40% on the capital legitimately invested."

Miami, Live Oak, and Inspiration; Inspiration, Miami, and Live Oak; Live Oak, Miami, and Inspiration; priority depending upon the particular group of interests represented; around these three has centred most of the copper news of the week. It is pretty well understood now that all three of the properties will eventually be consolidated and the reduction of the ores handled all at one plant. For the moment, negotiations are at a standstill, awaiting the reports of the various engineers who are to bring figures down to date as to developed tonnage and percentage of copper content. The engineers are Henry Krumb and W. H Aldridge, in behalf of the Inspiration, J. Parke Channing, of the General Development Co., for the Miami; L. D. Ricketts, of the Greene-Cananea, for the newly acquired Live Oak. From the estimates which have already been given out, it is figured that the combined properties will represent about 75,000,000 tons of developed ore, with an average content of about 2% copper.

The consolidation of these important coming producers has not had any perceptible effect upon the share market, although Miami is listed upon the New York Stock Exchange, and Live Oak upon the Boston Exchange, while Inspiration finds its market upon the New York Curb. This is probably due in part to a marked easing off in the metal market. The boom which was hurrahed into a semblance of activity last month has not developed any sturdiness of character, and, while the statement of the Producers' Association shows some falling off in the surplus, consumers still feel that they can save money by buying their copper as they need it, and that without taking any chances of becoming involved in a 'runaway market.'

Despatches state that the famous Camp Bird property, in Colorado, will close down, in February next, unless some new orebodies should be discovered in the meantime. The career of the Camp Bird has been so successful and so profitable that its close must be viewed with regret. The shareholders in Camp Bird are looking forward to a continuance of prosperity and dividends from the operation of the Santa Gertrudis mine in Mexico, recently purchased. The development up to the present time on this property is said to be wholly pleasing, and it is not anticipated that the final closing of the Camp Bird mill and mine will cause any cessation in revenue.

The traders in the New York market had braced themselves to stand the shock of a cut in the dividend of Goldfield Consolidated, and, having made up their minds to see the rate dropped, were somewhat surprised by the action of the board in declaring the customary distribution of 50c. per share. Nothing could mark the apathy prevailing in New York markets for mining shares more clearly than the indifference toward this issue, which was at one time, and for a long time, a market leader with a large public following that did many millions of dollars of real trading in the shares and created a market against which there was a great deal of high-class arbitrage. It is true that the issue has removed from the outside or curb market to the floor of the New York Stock Exchange, where the atmosphere is most hostile for all mining issues, but in the meantime the New York Curb has so far degenerated as to be left almost without friends or supporters either among its own members or with the public. In fact, it may be said to no longer have a public and to have lost all usefulness as a distributing market for new issues.

The report of the Copper Producers' Association covering the month of November is looked upon as exceedingly encouraging, as the refinery output shows a decrease, and both domestic deliveries and exports an increase, with the result that there is a gratifying shrinkage in the surplus. Production reported for the month was 111,876,601 lb., easily ten million pounds below normal and the smallest output for any one month since February 1911, when it was 109,828,297 lb. Domestic deliveries were 68,039,776 lb.; more copper than has been taken in any one month on this side of the water since January 1910, when home requirements took up 78,158,387 lb., a record which the last month does not crowd very closely. Export demand required 67,049,279 lb., which, while exceeding the figure for the two months preceding, is not above normal. The shrinkage in the total accumulated stocks is 23,212,454 lb., and the present surplus is 111,785,188 lb., a smaller burden than the metal market has had to bear at any time since in January and February 1910, when the figures for the surplus stocks were respectively 98,463,339 and 107,187,992 lb. While it is most encouraging for the copper metal market to see the bugaboo of accumulated stocks so materially decreased, and the technical position of the market is greatly strengthened thereby, it is to be borne in mind that, nevertheless, none of the factors which have made for the prevailing conditions have been actually eliminated. The decreased refinery output accounts for one-half of the surplus decrease, actual domestic consumption can hardly be said to have increased in view of the continued depression in general business, which is the main topic of discussion now throughout the East, at least, in the press and in every utterance by the men who have the public attention.

The Hedley G. M. Co., which operates the Nickel Plate mine in British Columbia, and in which a large number of the United States Steel officials are interested, has declared a 10% quarterly dividend, being a 3% regular quarterly distribution and 7% by way of extra disbursement.

The situation existing in the silver market is causing a good deal of discussion. The rebellion in China and the depletion of the silver reserve of the Indian Government have been the chief market factors against which some heavy pools have speculated. When the disturbance in China became acute it was found necessary to "resume specie payment," and Chinese bankers were forced to call for all London reserves of spot silver, giving the operators on the long side of the silver market a chance to reap some large profits. It has been expected that the Indian Government would soon be forced to come into the open market for silver for coinage purposes, and the same bull pools have been speculating against this demand. It will probably require from 50,000,000 to 75,000,000 oz. to complete the requirements of the Indian Government, if it finally comes into the market. If silver should be worked to the higher figures, around 65c., as hoped for by some of the market operators, they would not be the only ones to rejoice. Some of the Mexican mining camps with immense bodies of low-grade ore are in much the same position as some of the high-cost coppers, so-called, and would blossom out with a marked degree of prosperity, if any permanent market for silver could be established around 65c. While Cobalt is still a heavy silver producer, it seems to be admitted upon all sides that it has passed, or at least is now passing, the climax of its greatness. The present market for silver, between 55 and 56c., while showing a wide margin of profit for the Cobalt mines, still leaves many Mexican mine owners without a really safe margin upon which to operate. There are many districts, like Guanajuato, that have an immense assured tonnage, and, on 65c. silver, would become centres of great activity and expansion.

NICKEL PLATE MINE, BRITISH COLUMBIA.

The Arizona Copper Co. is submitting its scheme of reconstruction to the stockholders. Its No. 3 and 4 mills are to be dismantled and the No. 6 mill at Morenci is to be enlarged, a new power plant erected, and production attained of 43,500,000 lb. per annum. Copper recoverable from the mines is estimated at 400,000,000 lb. New financing will consist of the issuance of debentures to the amount of £500,000, which already have been underwritten. Mr. Ricketts will be a busy engineer, if he is to oversee the new construction work on the Arizona Copper, look after the development of the Live Oak, and continue to give attention also to the plant of the Greene-Cananea.

General Mining News

ALASKA

JUNEAU

The report of the Alaska Treadwell G. M. Co. for October states that 78,316 tons of ore was crushed and 1501 tons of concentrate saved. The estimated value of the free gold was $108,727; of concentrate, $89,730; the total production being valued at $198,457, with a realizable value of $196,473. The estimated net profit was $103,509.

PRINCE WILLIAM SOUND

The Valdez Bonanza M. Co. is said to be developing a 7-in. vein, on its Mineral creek property, which assays about $300 per ton.

THE TANANA

Remarkably rich ore, according to recent press reports, has been found on the Spaulding property on upper Dome creek. A hoist will be purchased for the mine.

SEWARD PENINSULA

The waters of Bering sea are reported to be lower than for years, and free from ice. Many 'beach-rockers' are getting good returns.

ARIZONA

According to the regular annual report of the Governor of Arizona Territory, to the Secretary of the Interior, for 1910, the mine production was slightly less than that of the year before. The gross production, as shown by returns made to the territorial auditor, was as follows: copper, 295,275,527 lb.; gold, 142,252,803 oz.; silver, 2,092,738,461 oz.; lead, 1,068,093 lb.; zinc, 6,134,418 lb. "There was a slight falling off in the production of copper," remarks the Governor, "some increase in the production of gold, a material decrease in the production of silver and lead, and a slight decrease in the production of zinc."

The gross value of the 1910 production was $42,229,282, which was $717,462 less than the value of the 1909 output. After telling of the activities of the various companies, including the shut-down of the Imperial Copper Co., the report on mining closes with a paragraph on the gold mines of Mohave county, which increased their production and added to their ore reserves during the year.

COCHISE COUNTY

The force at the Commonwealth mine, near Pearce, has been much enlarged in the past few weeks, since it was acquired by the Montana-Tonopah M. Co., and in the near future the erection of a 300-ton mill will necessitate the employment of many more men.

GILA COUNTY

(Special Correspondence.)—The following wire has jsut been received from W. A. Eaton, of Duluth, president of the Summit Copper Co., by his local attorneys: "Notify at once the directors of the Gibson Copper Co. of my intention to abandon the property, and that they can take possession before the expiration of thirty days." The Summit, formerly known as the Gibson mine, produced copper to the gross value of $1,250,000 under the management of the Gibson Copper Co. and held the almost unique position among copper mines of paying for itself from the start, the only capital invested, outside of some that was taken out of the mine, being $90. In June 1910 it was bonded to the Summit Copper Co., which worked it until October 1911. This company, at the time of closing down, was shipping chalcopyrite ore assaying 20% copper. The Summit officials have issued no statement since the mine was closed down, and there is much dissatisfaction among local shareholders, who claim that the funds of the company have not been properly accounted for and that Mr. Eaton and his associates did not take over the stock for which they had subscribed.

Assessment work for the present year has been nearly completed by the Warrior Copper Co. Spencer D. Wright, of Philadelphia, president of the company, has just made a visit to the property and states that nothing has yet been decided as to future policy. The option on control, held by the Warrior Development Co., a Duluth corporation, was relinquished a few months ago.

PINAL COUNTY

F. W. Dunkell, mining engineer and mine foreman for the Ray Con. company, was killed in a stope by a falling rock.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—The representatives of Bewick, Moreing & Co. are completing numerous surface improvements at the Plymouth Consolidated group. The laying of a line of water-pipe from the reservoir to mines will soon be in full swing. The properties lie in the Plymouth district. The California Con. M. Co. has secured a short extension on the time required to redeem the miners' liens on the Keystone mine, at Amador City, and the Wildman-Mahoney at Sutter Creek. It is stated in local mining circles that Amador capitalists will open and operate the Keystone, if the California Consolidated fails to assume control. The Keystone is credited with a production of about $17,000,000. The Bunker Hill continues a steady monthly disbursement of $7\frac{1}{2}$c. per share in dividends. It is understood that development below the 1950-ft. point is planned. At this level the vein is reported to be about 80 ft. wide. Elisha Hampton is superintendent. What appears to be an entirely new vein has been found on the 2800-ft. level of the Kennedy. It was tapped by the east cross-cut. The South Eureka company within a few weeks will establish connections between the South Eureka and Oneida workings. Unwatering of the Oneida shaft continues. In the main South Eureka workings good ore is being mined. The 60-stamp mill is operating steadily. W. H. Schmal is superintendent.

Jackson, December 9.

William J. McGee of San Francisco is trustee for the holders of liens on the California Con. M. Co. property, mentioned in the above despatch.

CALAVERAS COUNTY

Bishop & Co. have resumed operations at Vallecito, four miles from Murphy. Messrs. Lanyon, Martin, and Flormann are developing the Hercules Horseshoe property, formerly owned by Conliffe & Driver. At Douglas Flat a man named Adams is treating black sand with the cyanide process. Many individual miners are active, and there is much development in the East Belt district.

NEVADA COUNTY

(Special Correspondence.) — The Idaho-Maryland and Union Hill mines have ceased production because of the water shortage. At the Empire several men have been laid off, and development will be largely curtailed until rains set in. The company expects to keep the mill in action. The unusually dry season has seriously impaired the water resources of the Pacific Gas & Electric Co., and it is unlikely that sufficient water will be available until heavy rains set in.

The North Star Mines Co. has completed the installation of the electric pump in the Providence shaft. Together with two smaller machines, the big pump will drain the entire Champion group. The electric cables from the Colgate power-house to the Champion are in place. It is expected to have the pump in commission by Christmas. The water shortage in the Pacific Gas & Electric Co.'s reservoirs does not affect the Champion, as this company secures its supply from other sources. The Pittsburg is another unaffected mine. An effort is being made to raise sufficient money to resume operations at the Greystone mine near Snow Tent. It is planned to drive the adit about 700 ft. to tap the vein, giving backs of 450 ft. Surface showings are said to be encouraging. Local people chiefly are interested.

Nevada City, December 10.

The Midas mine at Randolph Flat, state advices from Grass Valley, has been bonded by J. W. Young, of Young & Young, a real estate firm of Sacramento. The property is owned by the Nevada County Midas M. Co. The mine will be unwatered, and a 5-stamp mill will be erected. Herbert James will be manager of the property.

Shasta County

(Special Correspondence.) Private advices from Boston state that the First National Copper Co.'s plan for the manufacture of sulphuric acid at Coram will not require stockholders to advance funds, as the company has about $600,000 in reserve. The First National owns the Balaklala mines and smelter, near Coram, and has been considering several plans for the resumption of activities. A large amount of Balaklala ore assays as high as 38% sulphur. Five stamps are being added to the 10-stamp mill of the Little Nellie mine, in the Iron Mountain district. It is expected to have the new battery in commission before the end of the year. Sinking the main shaft is under way, and much development work is being performed. J. F. Parthington is superintendent. Arrangements have been made for the resumption of activities at the Uncle Sam mine, eight miles from Kennett, in the Squaw Creek district. Five stamps will go into commission about the middle of December. Electric power will be used. The mine is controlled by the Standard M. Co., with Portland, Oregon, people principally interested. W. W. Bowers is superintendent. The management of the Victor mine, Harrison gulch, reports satisfactory conditions at the property. Good ore has been developed in the main workings and 20 stamps are dropping. Some work is going on at the Vulcan copper property, in which San Francisco people are interested. The intersection of a small body of high-grade ore recently was reported.

Redding, December 10.

Tuolumne County

The shaft at the Somerset mine, under bond to W. B. McCubbin and George Ash, will be sunk an additional 100 ft. to enable the more extensive development of the rich orebody uncovered while sinking the first 100 ft. The ore milled recently in the Spring gulch plant gave splendid returns, but no more will be hauled to that property for treatment, it being the intention to put up a mill of adequate size—probably 10 stamps—early in the coming year. It is now believed by W. J. Graham, superintendent of the property, that there will be no water in the ancient channel which the Gold Ship M. Co. has been expending so much money to open. Equipment to handle a heavy flow, which it was thought would surely be met, was recently erected, but the only water thus far comes in at another part of the mine.

Articles of incorporation of the Harvard Mine, Inc., organized under the laws of Massachusetts, were filed in this county last week. The capital stock is $100,000 common stock; par value $5. The 20,000 shares of stock are to be issued as follows: To be paid for in cash, 1000 shares; in real property, 14,000 shares; in personal property, 5000 shares. The incorporators are James R. Simpson, Edward H. Mason, W. B. Buckminster, and Kalman Haas.

The work of retimbering the Santa Ysabel shaft is about completed. A quantity of ore is to be taken out of the Mammoth mine at Jacksonville and milled, and if results are satisfactory the property will be developed. The shaft at the Starr King is being sunk another 100 ft. The new 5-stamp mill is pounding steadily, and it is said the results are gratifying. It is reported that a company is about to begin operations at the Columbus, situated about two miles north of Tuolumne, which has been idle for many years. The Clio mill is being overhauled and will be started as soon as possible. The two 5-stamp batteries recently added to the New Albany mill are now in operation with the original 10 stamps, and between 60 and 70 tons of excellent ore is crushed per 24 hours.

Tuolumne, December 9.

COLORADO

El Paso County

Late press reports state that the Golden Cycle mill, since the temporary shut-down of the United States R. & R. Co.'s mill, is treating over 1000 tons of ore per day. In case the cyanide plant will be overtaxed in treating the increased amount of ore, another Edwards roaster will be added to the equipment. The Portland company and the Golden Cycle are quoting the same rates.

The Golden Cycle M. Co. paid its regular monthly dividend of 2c. per share on December 1. The total dividends paid in 1911 amount to $1,410,000.

La Plata County

The Durango smelter of the A. S. & R. Co. has been closed for the winter. One of the main reasons for the shut-down was the recent floods, which washed out the railroads and cut off the ore-supply.

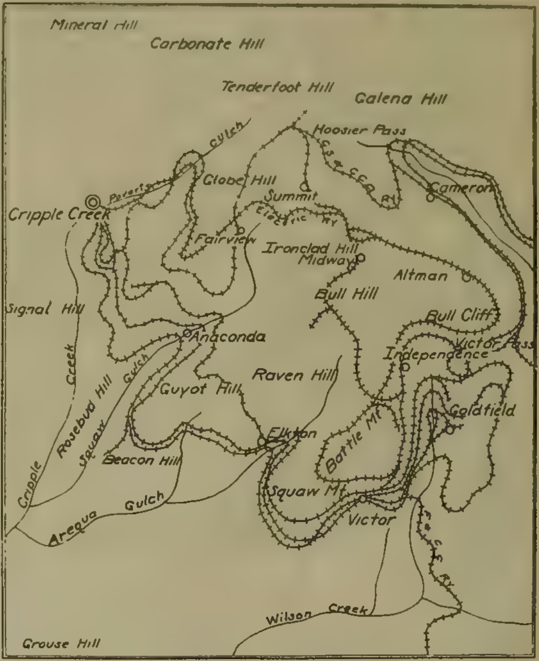
San Miguel County

The Liberty Bell mill is crushing 15,000 tons of ore per month with 80 stamps in operation.

Teller County (Cripple Creek)

The Union Leasing Co., operating the Gold Sovereign on Bull hill and the Husted shaft on Beacon hill, consigned 68 cars of ore to the valley plants during November. The ore yielded $8 to $45 per ton, the more valuable ore coming from Beacon hill. C. G. Jackson is superintendent for the company.

The Jerry Johnson, Ironclad hill, shipped 46 cars of ore during November. This amount was less than was expected, the shortage being due to delay in the construction of an electric compressor.



CRIPPLE CREEK DISTRICT.

The Colorado Mining & Investment Co. has found ore assaying over 7 oz. per ton in the Rice vein, 170 ft. below where Jones & Co. have been operating for some time.

The Granite company shipped 70 cars of milling-grade ore during November. The Western Investment Co. sent out 40 cars of ore from the Victor, Bull hill, and the Ophir, Raven hill, during November.

According to a statement by the management, the Stratton's Independence mine filled with water to an elevation of 8864 ft. in the shaft, when the pumps were stopped in 1907, owing to the cost of pumping and the refusal of adjoining properties to share the expense. It is asserted that the Stratton's Independence was really pumping for its neighbors as well as for itself. The mine's 900-ft. station is at an elevation of 8947 ft. above sea-level, and from the levels above the water about 1500 tons of ore per month was mined. The ore on the average assayed $26. Pumping was resumed last month and the lessees again started development at the 1050-ft. level.

IDAHO

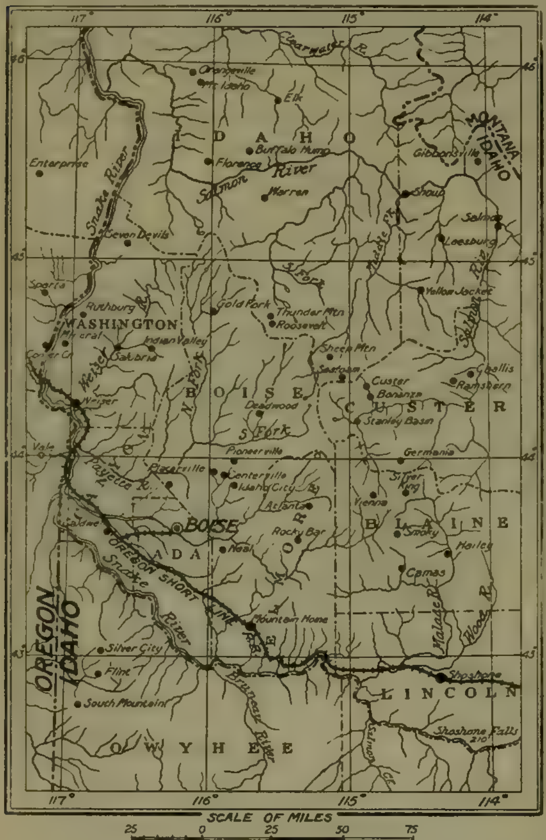
Bonner County

William Baptiese, of Lakeview, reports that capitalists of Cleveland and Pittsburg are planning to drive a 1500-ft. tunnel on the Vulcan mine at Lakeview.

Idaho County

(Special Correspondence.)—A rich find has been made on the Laufer & Davis property on Logan creek. A 4-in. streak of free-milling ore which assays an average of $2400 per ton, has been opened up at a depth of 100 ft. On the surface a series of open-cuts and shallow shafts yields rich pannings.

An adit is being driven on the Victor claim. It is now in 285 ft., and should cut the main vein of the system at a depth of over 200 ft. in another 100 ft. of distance. In the discovery shaft, at a depth of 30 ft., some fine specimens of native gold were obtained; the vein and feeders can be traced on the surface for several thousand feet. This property is situated on Profile creek.



SOUTHERN IDAHO.

The Eagle M. Co. again is operating the 10-stamp mill after a three weeks' shut-down owing to the freeze-up of the cyanide tanks.

Warren, December 9.

Lincoln County

Newspaper reports state positively that construction will be started at once on a branch railroad to connect the Prince Consolidated property with the Salt Lake Route station at Pioche. Much of the preliminary survey work has been done. The road is to be in commission, it is said, within two months.

Shoshone County

Five and a half feet of ore, of which more than 50% is of shipping grade, has been opened in the cross-cut on the 500-ft. level of the Marsh mine at Burke.

The Bunker Hill & Sullivan M. & C. Co., operating the Bunker Hill mine at Wardner, has disbursed $65,000 as its dividend for December, bringing the total to date to $13,159,650.

The Snowstorm M. Co. is having plans prepared for a new concentrator and leaching plant, according to recent newspaper reports. The capacity and cost proposed for the plant have not been announced. The Snowshoe mine is situated near Mullan.

MONTANA

Silverbow County

(Special Correspondence.) — According to the official figures, the Washoe smelter produced 15,700,000 lb. of copper during November, and the Great Falls smelter 5,150,000 lb., making a total production for the month of 20,850,000 lb. This was the smallest amount of copper turned out in any one month this year, the month of February coming next with 20,900,000 lb. In this respect it may be mentioned that, in the figures given, the production of the North Butte and the Tuolumne companies are included and both amount to about 2,500,000 lb. The only other producing company not included in the figures is the East Butte, and its output last month was about 900,000 lb. of copper.

According to information from a reliable authority, the proposed concentrator of the Boston & Corbin company will not be constructed until next spring, if at all, the whole matter hinging on the returns received from ore to be sent to different plants for treatment. There will be several carloads sent out and an effort will be made to ascertain exactly the kind of treatment which should be used. An interested party says that the money for the erection of the concentrator is in the treasury, but the directors feel that no false step should be taken in the way of expending the money.

The Little Annie of the Butte-Alex Scott company has been closed down. This mine was opened early in the summer and at once came into prominence through the discovery of some rich silver ore. Some shipments were made, and the result was so satisfactory that the company was believed to be on its way to a high state of prosperity. However, the directors did not feel justified in spending any money in sinking and opening up the orebody, so the mine was closed down. Regular shipments are being amintained to the East Butte smelter from the Alex Scott, although they do not amount to more than 30 tons per week.

Butte, December 9.

On December 8 the Pilot Butte cross-cut from the 1300-ft. level of the Black Rock shaft, in the North Butte section of this district, had penetrated 28 ft. in a large lode, mostly copper ore of commercial grade, and was not yet through the vein. The lode is believed to be the northwesterly extension of the Berlin vein of the North Butte company. No figures as to value have been disclosed, except that the ore is of commercial grade.

NEVADA

Esmeralda County

George Wingfield has released his option on the property held at Antelope Springs, of which the purchase price was to be $225,000. It is asserted that the terms of the option did not suit him.

Press reports state that there is renewed activity in the Cactus range district, 20 miles from Goldfield, and that three properties are making good showings. The ore is said to be similar to that of the Goldfield and Tonopah districts.

The Goldfield Con. M. Co. has declared a dividend of 30c. per share, payable January 31 to stockholders of record on December 31.

In addition to declaring the regular dividend of 30c. per share, the Goldfield Con. M. Co. has declared a special dividend of 20c. per share, payable on the same date. The company in the fiscal year ended October 31 earned about $400,000 in excess of dividend requirements. It is rumored that the company is seeking to buy another mine, although an early end to the Goldfield mine is not feared. The production for the fiscal year just ended is analyzed as follows:

Month 1910:	Tons.	Gross value.	Value recovered.	Net profit.	Net per ton.
November	24,956	$ 873,405.55	$ 817,756.13	$588,609.94	$23.60
December	25,550	746,761.00	709,069.86	488,708.00	19.13
Month—1911:					
January	27,692	798,177.24	742,980.28	552,626.95	20.32
February	23,675	973,730.78	913,684.43	719,325.04	30.38
March	25,714	1,119,951.75	1,064,068.54	846,283.13	32.91
April	28,253	1,061,496.53	1,010,073.91	796,151.64	28.18
May	29,450	962,110.35	909,441.12	679,537.16	23.07
June	28,540	923,472.87	874,180.20	646,830.48	22.67
July	29,253	848,429.44	802,117.06	582,021.68	19.89
August	30,580	910,477.60	862,661.80	634,658.42	20.75
September	26,766	676,383.20	636,888.00	444,366.25	16.60
October	30,626	860,153.81	819,858.02	616,141.87	20.12

Humboldt County

Preparation is being made for resuming development of the First National M. Co.'s and Mammoth National M. Co.'s properties in the National district.

Lyon County

The Empire property, including the old smelter building near the Yerington station, recently was sold at sheriff's sale. The principal stockholders in the company bought the property.

Reports from Yerington early in the week were to the effect that the new smelter at Thompson, Mason valley, would be blown in some time between December 15 and 20. The first shipment of copper ore from the Nevada-Douglas to the Thompson smelter was made December 1. This property is to deliver, according to a contract, 10,000 tons of ore per month to the new smelter.

In a statement to shareholders, W. Mont Ferry, president of the Yerington Central Copper Co., recently stated that unless a unanimous vote enabled the company to change its stock from non-assessable to assessable shares, the company would lose all its property at the suit of its creditors. The company owes on loans made by various stockholders $18,326 and to banks $46,200. No officials of the company have drawn salaries. It is believed the directors will not be able to sell the property. First mortgage bonds cannot be placed. The larger stockholders do not feel called upon to pay more than their share, pro rata, of the indebtedness. About $10,000 of indebtedness and interest must be paid this month, and the balance in February 1912. The property is considered valuable, and it is believed that some time it can be sold for enough to pay all indebtedness and yield a profit. Proxies are to be sent to Herbert M. Wells, secretary of the company, at Salt Lake City.

Nye County

The Berlin mine, which is reported to have produced $7,000,000 before the 1907 panic stopped development, is seeing renewed development, and the management believes that the present work will open up new orebodies. The tailing-dump is being treated at the Berlin mill with the cyanide process. The capacity of the mill is to be doubled in the near future.

The Shoshone Quicksilver Co. is preparing for active development at its property, at Ione, seven miles from Berlin. Only lack of railroad facilities is stopping active development in the North Bell M. Co.'s Richmond mine, according to late reports, as there is ore in sight. The nearest railroad point is Luning, about 50 miles from the property.

The shipments last week for the Tonopah district, according to a summary by the *Tonopah Miner*, amounted to 8376 tons, valued at $209,440.

Storey County

The Comstock mines last week, according to a summary made by the *Virginia Chronicle*, produced ore valued at $33,806. The Ophir made the largest production, with $21,349 to its credit. The Mexican produced ore valued at $7857, and the Crown Point ore valued at $4600.

White Pine County

There was a walk out of short duration recently of the men employed on the churn-drills on the Nevada Con. property at Copper Flat. The drillers were receiving $5, and the tool-dressers $4 for twelve hours on a nine-hour schedule of $4 and $3, and for a while objected to a ten-hour day on the same schedule.

In a report of the Ely Con. Copper Co. for the 11 months ended November 30, it is stated that the water, which gave some trouble in shaft-sinking, is now being handled with ease. Among other development, there was found near the 500-ft. level a vein between 5 and 6 ft. wide assaying on the average 3.84% copper and $1.10 gold and silver per ton. Westerly workings are in oxidized copper ore assaying nearly 6c. copper and $2 gold and silver per ton. The claims, about 370 acres, are valued at $10,326,997.

NEW MEXICO

Quay County

More than 100 claims have been filed during the past week, principally for the Bad Lands district, 13 miles east of Tucumcari. An abortive oil-boom was started in the district last summer, but now the mineral resources of the place are receiving renewed attention.

Socorro County

(Special Correspondence.)—The new power plant building for the Socorro mines is rapidly nearing completion. Some of the machinery for same has been delivered and considerably more is on the way. Ten of the Ernestine M. Co.'s new Allis-Chalmers stamps will be dropping this week and the erection of 10 more will be started. Mine developments continue showing up ore of a grade above the average in this camp. The bullion recovery for the last 10 days of November was 9480 oz.; four tons of concentrate was shipped in the period. The past week's ore reduction was 630 tons. The Treasure M. & R. Co. plant lately has had an abundance of water for power generation, aand the mine and mill have been operating at full capacity. About 70 tons is treated daily. The ore haulage crew will soon be equipped to transport between 80 and 100 tons per day from mine to mill, a distance of about three miles. Regular shipments are being made by the Oaks Company to the Deadwood mill from development on the Pacific, on which mine the adit was advanced 35 ft. during the week. A contract has been let by the Ann Arbor company for driving the main adit.

Mogollon, December 8.

OREGON

Benton County

(Special Correspondence.)—A general advance in the mineral output of the State and the development of mining into one of Oregon's leading industries, is the prediction of H. M. Parks, of the State Bureau of Mines, head of the Oregon Agricultural College School of Mines. A vast mineral wealth besides the gold, silver, and coal awaits capital and men to fit it for the needs of industry—such raw materials, for example, as soda, cement, and many other natural elements. Mr. Parks will shortly issue a bulletin from the Bureau of Mines showing the 1910 mineral output of the State to be worth $4,200,546, an increase of nearly $2,000,000 over the 1900 output. Gold, silver, granite, sandstone, limestone, clay, mineral water, copper, sand, gravel, lime, and gypsum are in the list of valuable mineral products of the past year.

Corvallis, December 9.

UTAH

BEAVER COUNTY

The Moscow M. & M. Co. has declared a dividend of 1c. per share, this being the second dividend. The first was paid September 15. There are 797,600 of the 1,000,000 shares issued. The company has been shipping about five cars of ore per month.

SAN JUAN COUNTY

The Bluff & Norwood company has 'brought in' the Galloway oil well in the San Juan district. Oil was found at a depth of about 1800 ft. in the Honaker sand. The company plans to erect a pump at once.

SUMMIT COUNTY

(Special Correspondence.)—Beggs & Miller, who are building a milling plant of 3 Wilfley tables and 24 MacQuisten tubes at Park City for the purpose of re-treating the tailing that has accumulated at the dry-concentration mill of the Grasselli Chemical Co., expect to have it ready to operate before the first of next year. This tailing consists of zinc and iron sulphide, lime, and silica. The first step in the process will be to pass the tailing over the tables for rough concentration; the middling resulting from this is to be treated in the MacQuisten tubes, by which the most of the lime will be eliminated and the iron content much reduced, leaving a tolerably clean concentrate that will run higher than 50% zinc. The lime passes out with the silica as tailing, and its separation from the zinc is important, because buyers of ores for zinc smelters regard the presence of lime as especially objectionable, and such ores as have been practically freed from lime find a ready market. This plant will have capacity to treat 35 tons per day.

Park City, December 11.

WASHINGTON

FERRY COUNTY

The Insurgent M. Co., owning the Insurgent claim at Republic, Washington, has just declared its fourth dividend of $2500, at the rate of 1¼c. per share. This brings the total of dividends paid by the company to date to $25,000, or 25% of the par value of its capital.

SPOKANE COUNTY

The Spokane Mining Men's Club, composed of operators in the four Northwestern States, has started a campaign for such reciprocal relations between the United States and Canada as will permit the free entry into this country of Canadian lead and zinc ore and products.

AUSTRALASIA

The Commonwealth Oil Corporation is operating at Newnes and in the neighborhood with a capital of $6,083,000, and the British Australian Oil Co. at Temi, near Murrurundi, in the Liverpool ranges, with a capital of $1,460,000, states the *Daily Consular Report*. Both are purely British-Australian ventures, financed and controlled from London. There are also Tasmanian ventures struggling valiantly, especially the Tasmanian Oil & Shale Co., at Latrobe, but they are said to be badly handicapped, owing to lack of capital. And without capital there is no hope of conducting successful shale oil mining and refining upon a commercial scale.

CANADA

BRITISH COLUMBIA

A. N. C. Treadgold is reported to have purchased all claims on Dominion creek, from Granville to Head creek. The placer ground extends for about 27 miles. The same report, from Dawson, states that he has acquired more than 100 claims on Hunker creek from the Hunker Development Co. The Treadgold company recently completed a four-mile conduit to supply water for hydraulic purposes from the Klondike river.

The Hedley G. M. Co. has declared its regular quarterly 3% dividend and an extra dividend of 7%. The strike of the coal miners has been settled, and the Granby Con. M. S. & P. Co. will resume operation at its Grand Forks smelter in the near future. The British Columbia Copper Co., Ltd., will resume development.

ONTARIO

According to an official statement by Ambrose T. Monell, managing director of the 'Big Dome' mine, there are two drifts at the 50-ft. level, one of which runs uniformly for 136 ft., assaying $28 per ton; the other, running parallel, assays $30, except for the last 20 or 30 ft., where it assays over $40. Below that level diamond-drilling has shown good ore, but the grade cannot at present be definitely announced. Under what is known as the 'golden stairway,' a diamond-drill put down 200 ft., showed high-grade ore. The diamond-drill cores, taken at points 1000 ft. apart and put down 200 to 750 ft., give varying results up to as high as $1000, but it is impossible to strike an average.

Press reports state that high-grade ore has been found at a depth of 200 ft. in No. 4 shaft of the McIntyre mine. The vein at that point is 24 ft. wide. The McIntyre mine is in the Porcupine district.

The Wettlaufer-Lorrain company of Cobalt has declared its regular quarterly dividend, payable January 5, of 2½%, and an extra dividend of 2½% payable the same date. The company's report showed that on November 27 there was $86,559 cash on hand; silver on hand and in transit, $99,677; total, $186,267. The liabilities were $30,050. The new mill is almost completed and should be in operation in a few weeks.

HAWAII

(Special Correspondence.)—Topographic surveys on the island of Hawaii have been begun by officers of the U. S. Geological Survey. The survey of Kauai has been completed and advance proofs of the map are now available. The final prints will not be ready for a few weeks longer. The scale of the map is 1 to 3160, and in style it follows closely those made on the mainland. The work has been under the charge of C. H. Birdseye, who has now gone to Washington but will return to the Islands in February. T. G. Gerdine, who has been inspecting the work in the Islands, announces that the survey of Maui will be begun in July.

Honolulu, December 1.

MEXICO

CHIHUAHUA

The Alvarado M. & M. Co. has acquired the Parral Power & Reduction Co.'s plant, a short distance from Parral, on the Parral y Durango railroad.

Messrs. Stallforth have given an option on the Sierra Madre property to an English syndicate. The price named is ₱100,000, states a report from Parral.

The Ginther interests have taken over the Refugio mine from the Refugio M. Co., on an option.

Important finds of gold ore are reported at the La Chamaquita and Las Palmas, Francisco Gomez y Socios properties. The vein yields ore assaying 4 to 5 oz. gold and 1½ kg. of silver.

Reports from Parral state that Pedro Romero and Everado Ortego have denounced ten *pertenencias* in the San Lorenzo district of Iturbide, naming their claims 'La Luz.' Isidoro Carbeo has denounced five *pertenencias* in the El Puerto del Arroyo Hondo, on the State line between Chihuahua and Sonora.

SONORA

The new reverberatory-furnace replacing and taking the name of the old No. 1 furnace of the Cananea Con. Copper Co. was placed in commission last week. This makes two new furnaces installed this year. Each is 17 by 100 ft. and has an arch in proportion. No. 1, however, is more strongly reinforced, and has a lighter steel-plate construction front, than the older No. 2 furnace.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press

Miners' Lien Priority

The president of a mining company purchased a stamp mill under a conditional sale contract and caused such mill to be erected and permanently affixed to the freehold at the mines of the company. Miners who performed work for the corporation owning the mines were entitled to liens on the stamp mill as the part of the freehold, the conditional agreement of purchase not being recorded was invalid to them where they had no notice of such condition.

Washburn *v.* Inter Mountain Mining Co., (Oregon) 109 Pacific, 382.

Who May Hold a Miners' Lien

Under the statute of Oregon a foreman at a mine whose business it is to see that the work of mining was done in different places, and who framed timbers and helped the men, took part in the erection of the mill and did other things generally to assist in the furtherance of the work, is not such an executive representative of the mining company as to preclude him from obtaining a miners' lien upon the property of the company for such services performed by him.

Washburn *v.* Inter-Mountain Mining Co., (Oregon) 109 Pacific, 382.

Mechanics' Lien on Mining Property—Filing

Where the mining property and all the improvements are in the hands of a receiver, and all the parties in interest are brought into court within four months after the date upon which material was last furnished or labor last performed under contract, this will be deemed a sufficient filing of the claim within the Oklahoma statutes and the court may adjust the rights of all lien-holders. And a statute authorizing mechanics' liens on improvements applies to a coal mine, as a coal mine is an improvement within the meaning of the law.

Peaceable Creek Coal Co. *v.* Jackson, (Oklahoma) 108 Pacific, 409.

Stock in Mining Corporations

The term "treasury stock" as used in the statute of Nevada which regulates the issuance by mining corporations of treasury and promotion stock and requires the stamping of certificates, means certain stock that is set aside for the actual development of the property, while "promotion stock" is that issued to those who may originally own the mining ground or rights connected therewith in consideration of their transferring the mining property to the mining company, but such stock as is issued to promoters for promoting the corporation of the company. But such statute had no application to any stock issued prior to April 15, 1909, when the statute went into effect.

State *v.* Manhattan Verde Co., (Nevada) 109 Pacific, 442.

Notice of Location of Mining Claim

The statute of Nevada does not require the notice of the location of a mining claim to be recorded. And a notice of location of such a claim, though not in strict compliance with the statute as a certificate of location, and therefore not evidence of the act of location, is admissible in support of a claim in adverse possession. The rule is that such a notice is not required to be strictly exact, and is not controlling, and that courses and distances given therein yield to the monuments erected on the ground. It is also the rule that the filing of a defective certificate of location, or the failure to file any certificate does not invalidate the claim. Neither does the fact that the end lines of a mining claim are not parallel invalidate the location, but only affects extralateral rights.

Gibson *v.* Hjul, (Colorado) 108 Pacific, 759.

Book Reviews

Any of the books noticed in these columns are for sale by or can be procured from, the Mining and Scientific Press

The Metric System. By A. D. Risteen. Pp. 196. The Hartford Steam Boiler & Inspection Co., Hartford, 1911. For sale by the *Mining and Scientific Press*. Price $1.25

Everyone who has had occasion to convert English weights and measures into their metric equivalents, and conversely, is familiar with the irritation produced by finding that the particular units required are not included in the tables at hand. But the tables in this handbook are so numerous that this annoyance will be reduced to its lowest terms. The book is of convenient pocket size and is well and strongly bound.

Electrical Mining Installation. By P. W. Freudemacher. Pp. 181. Ill. D. Van Nostrand Co., New York, 1911. For sale by the *Mining and Scientific Press*. Price $1.

This little handbook is especially intended for the use of colliery engineers and contractors, but also contains much that will be of service to the metal miner, who will be grateful for a brief presentation of the subject in its simplest terms. Some confusion may arise from the imprint of New York on the title page, for the author's references to "this country," and the legislative acts cited are evidently intended to apply to England.

The Design of Walls, Bins, and Grain Elevators. By Milo S. Ketchum. Pp. 556. Ill. Second edition, revised and enlarged. McGraw-Hill Book Co., New York, 1911. For sale by the *Mining and Scientific Press*. Price $4.

This book is one of the evidences of the high degree to which specialization has been carried in engineering. The somewhat bulky volume is entirely devoted to the analysis of the stresses due to granular materials, and their application to the design of structures for containing materials of this class. The admirable way in which this has been done is evidenced by the demand for a second edition of a work of such special interest. In the revision nearly 150 pages of new material has been added, and those portions of the book dealing with reinforced concrete have been rewritten. Though the discussion is chiefly of grain bins and grain elevators, engineers engaged in ore-dressing design and practice will find much that is of service to them.

Rock Drilling. By R. T. Dana and W. L. Saunders. Pp. 319. John Wiley & Sons, New York, 1911. For sale by the *Mining and Scientific Press*. Price $4.

This volume, compiled from data collected by the engineers of the Construction Service Co., is chiefly intended for civil engineers, most of the data bearing upon quarrying and river and harbor improvement work. The first three chapters, which deal with the general features of drilling, are of universal applicability, contain much that is new, and are well written and arranged. An exceedingly valuable feature of the book is the free use of diagrams and charts, in which a large volume of data is collated in a form which allows ready comprehension. Not so much can be said for the photographic illustrations, and it is difficult to perceive any significance for many of those used in chapter V. The accurate records of data upon many different kinds of work make the volume especially valuable; the 40 records of the cost of drilling given on pages 67 to 70, for example. These are not the usual bare figures, but are accompanied by all the other data necessary to obtain a proper conception of working conditions. The book will be of the greatest service to civil engineers, and mining engineers will find much that is useful in it. Fortunately the book-making has been done by professional publishers; too frequently volumes of this sort are privately printed, with the result that from poor arrangement of material the usefulness of the book is greatly decreased. The book, therefore, is a highly satisfactory one.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

L. D. **Ricketts** is in London.

W. J. **Loring** has gone to Burma.

Howard D. Smith is at Ely, Nevada.

R. **Gordon Walker** is in Mexico City.

H. S. **Denny** has left London for Mexico.

W. S. **Noyes** has returned to San Francisco.

Mark B. Kerr was in San Francisco this week.

R. S. **Rainsford** was in San Francisco December 10.

Dyke V. Keedy is in Texas on professional business.

James Douglas left London December 9 for New York.

Herbert P. Sawtell was in San Francisco on his way East.

T. G. **Gerdine** has returned to Sacramento from Honolulu.

J. **Malcolm Maclaren** left on December 14 for Valdez, Alaska.

R. T. **Bayliss** is expected in London from Mexico in January.

Z. **Cushing** was at Mazatlan, Mexico, and has gone to Honolulu.

Robert A. Bryce was in San Francisco, returning from Mexico City.

S. F. **Shaw** has removed from Los Angeles, California, to New York City.

Fred Searles, Jr., has been appointed geologist for the Goldfield Consolidated.

Gaston Claus will sail from New York for Havre on *La Provence*, December 21.

C. H. **Birdseye** passed through San Francisco traveling from Honolulu to Washington, D. C.

Robert H. Richards is spending a week at Hancock, Michigan, on professional business.

The address is wanted of M. J. **Silvia**, who before the earthquake and fire, lived in San Francisco.

C. W. **Goodale**, who stopped at Honolulu on his way home from Japan, arrived in San Francisco December 12.

Carl J. Stahl spoke to the mining men of Ouray on December 9 on the 'National Forests and the Prospector.'

George W. Schneider, professor at the Colorado School of Mines, visited Telluride and Ouray on December 8 and 9.

H. V. **Winchell** lectured before the Geological Club of the University of Minnesota, December 7, on 'Secondary Enrichment of Ore Deposits.'

George L. Mackenzie has resigned his position as senior examining engineer for the Tharsis Sulphur & Copper Co., Ltd., of Spain, and intends settling in California.

A. E. **Anderson**, of the E. I. Du Pont de Nemours Powder Co., delivered a practical talk on 'Recent Experiments in Explosives' to the mining men of Telluride on December 8.

O. **Bergstrom** has accepted the position of general manager for the Rea Consolidated Gold Mines, Ltd., and remains as consulting engineer for the Calaveras Copper Company.

Obituary

R. M. **Brereton**, a well known mining and civil engineer, died at his home at Woodstock, Oregon, on December 7, at the age of 78. Mr. Brereton was connected with the construction of the Calcutta-Bombay railroad from 1857 to 1870, and came to America in 1871. For a number of years he was identified with mining and irrigation enterprises in California and the Northwest, and was associated with the Jonathan Bourne mining interests in Oregon.

EDITORIAL

COLORADO citizens have an effective way of doing things, and elsewhere in this issue, Mr. Walter A. Koch describes the means taken by an earnest and progressive group of men to stimulate prospecting and the development of new mining areas in that State. We wish the Colorado Grubstake & Mining Company the fullest measure of success.

VERSATILITY is not the least of the characteristics of Mr. Thomas A. Edison, who has recently proposed to construct concrete houses at a cost of $1000 each, and provide them with concrete furniture for $200 additional. Presumably the settee used by the daughter of the house and her young man would be reinforced. But this is not all; Mr. Edison is about to devise a generic law which will take the place of the Sherman Act. Apparently, Mr. Edison considers himself the national 'Lady from Philadelphia.' Meanwhile we are still looking for the automobile which he was about to make so cheaply that none would be too poor to be able to afford one.

PLEAS for revision of the American mining law are becoming increasingly frequent, and there is a general feeling that the time is ripe for change. Committees from the American Mining Congress and the Mining and Metallurgical Society of America are giving the subject careful consideration, and it is expected that Congress will this year take at least preliminary steps toward revision. In Canada, as well as in the United States, the matter has been up, and an able committee has prepared a draft for a new law, which is soon to be submitted to Parliament. Any change made should take full cognizance of the past, and therefore the discussion of the mineral land laws of the United States by Dr. James Douglas, published on another page, is especially timely. As always, what Dr. Douglas has written is scholarly and well worth while. We commend it to our readers, reserving, for the present, our comment on the whole matter.

HONOLULU is at the cross-roads of the Pacific. Living at such a prominent meeting-place of lines of travel has its pleasures, but also imposes obligations. One of these, the duty of hospitality, the citizens of Honolulu take most seriously. To judge from the experience of a trans-Pacific traveler, life in Honolulu would seem to consist of one continuous round of gaiety. A Government engineer detailed for duty in the Islands complained humorously that he found no time for work. Evidently the tropics richly reward the skilled Anglo-Saxons who care to make them their home. There is no mining in Hawaii, though there is some quarrying, and just now especially interesting tunnel work is under way. Absence of any local mining engineers did not, however, prevent the Institute members returning from Japan from being received as among brothers. The Hawaiian Engineering Association arranged for them a visit by the Naval tug *Navajo* to Pearl Harbor, the new dry-dock, Fort Kamehameha, a sugar plantation and refinery, and a luncheon tendered by the Commercial Club of Honolulu. It was only the absence of mines that prevented the party from staying indefinitely.

IMPROVEMENT in the copper situation has been made much of during the past fortnight, and the present turn in the market is being hailed as marking the passing of the 'menace of accumulated stocks' and as ushering in an era of higher prices. There is no argument existing as to the conditions that have prevailed or as to the causes responsible for the conditions, but it is somewhat difficult to perceive which of these causes have been eliminated and what is to prevent a recurrence of the same conditions. If a reduced surplus is to make for higher prices, will not higher prices stimulate production to a point where accumulated stocks will once more constitute a heavy burden? Perhaps the underlying skepticism is most clearly shown in the share market, where under normal conditions the future is always forecast with remarkable accuracy and most quickly discounted. Notwithstanding the advent of a 14-cent copper market, advances in copper shares have been but nominal, in many cases there have been actual declines as compared with May last, when the metal was at the lowest figure for the year. The truth is that no small part of the difficulties apparent in the copper situation are not peculiar to copper. Business is generally depressed, and stable conditions must first be secured as a basis for increased prosperity.

POLITICAL conditions abroad have much improved during the week. The Moroccan situation is much easier, and the dispute between Russia and Persia is about to be amicably terminated. And in China an effective step toward peace has been taken in the presentation of a joint note by the United States, Great Britain, Germany, France, Russia, and Japan, pointing out the necessity for the restoration of stable conditions under some form of government. What this form will be, only those whose opinions are valueless are venturesome enough to prophesy as yet. The international relationships of China are extraordinary, and cannot be considered in the ordinary way. Such an action in the case of a civil disturbance in any other country would probably be regarded as an impertinence, but the foreign interests bound up with the material prosperity of China through the cohesive power of loans, put the matter in a different light. The Imperial Maritime Customs, the great source of revenue to the Peking government, has been practically under foreign supervision for years, and only recently has the Chinese Government obtained any large degree of control in its administration. Nations are remarkably like individuals, and if affairs in China are conducted in a way inimical to the financial interests of the great Powers, it is not improper that they should issue to themselves international letters of guardianship, though with proper foresight and the exhibition of diplomacy and tact it is to be hoped that such an outcome can be avoided. It is not too much to hope, then, that within a few months reasonably stable conditions in China can be restored. The critical problem is the securing of an adequate national revenue. This was formerly drawn from a variety of sources, such as tribute from the eighteen provinces, the salt gabelle, the maritime customs, and others. The total has long been barely sufficient to meet the current needs of the central Government, and the capital for national undertakings has been obtained through foreign loans, which have given rise to the present outbreak. Tribute from the provinces has been entirely ceased, and it is probable that no little difficulty will be experienced in securing its resumption. There appears to be a good deal of wrangling with regard to the form of State. The revolutionists, [illegible] to clear the way and [illegible] that the present [illegible] effect will be [illegible]. The [illegible] more [illegible] than [illegible] the gradual strengthening of the central Government [illegible] at best, be greatly set back by the outbreak [illegible] desirable but essential to the rapid, sound, and right development of the nation and the national resources. The problem of readjustment is also likely to be complicated by a famine, more widespread and distressing than that of last year, which threatens a large part of east central China during the winter and spring.

Merry Christmas

Christmas, appropriately enough, is a combination of pagan and Christian observances, thereby showing the universality of its appeal. The pagan element is kept discreetly in the background, much as New England spinsters have been known to modestly drape the 'limbs' of the piano. Nevertheless, it is always there, just as the pagan is an essential feature in the individual character. We are too civilized now-a-days, and we thereby lose much. Physically we cannot return to medieval conditions, nor is it even desirable that we should do so, but gain would accrue from some return to the mental atmosphere of the Middle Ages, and the lapsing of the stereotyped custom of gifts that too frequently are a source of but little pleasure to either recipient or giver. Joy is but a relative emotion, and may be less felt by the millionaire than by the humble miner who, in the content of mind resulting from an honest and honorable occupation, and with the hearty appetite derived from arduous though healthful labor, dines heartily off bacon, flapjacks, and coffee, while outside his cabin door stands his Christmas tree, powdered with real snow and lit with a thousand candles by the sun of Christmas day. Though its branches are but bare, we hope he may find its roots decked with the gold he seeks, and we wish him, and all our readers, a full measure of Christmas good cheer and a happy and prosperous New Year.

Foreign Trade and the Steel Corporation

The United States Steel Corporation has recently been discussed from numerous standpoints, but one of the most interesting contributions to current criticism is an article entitled 'A British View of the Steel Corporation' by Mr. T. Good, published in the *Atlantic Monthly* for December. The Corporation is a large institution, and we, who live close to it, labor under some difficulty in getting a general view. Mr. Good, from his vantage point of practical experience in the industry and residence in England, boldly sketches the outlines and fills in details, though, be it said, against a somewhat somber background. He gives high and deserved praise to the officers of the Corporation for having introduced economies in mining, transportation, and manufacturing, paid liberal wages and dividends, provided adequately for maintenance and for new construction of the highest type, and regulated prices and business. The old disturbing ups and downs of the steel business have disappeared, and Mr. Good points out what it is easy to forget, that while the Corporation refused to lower prices in 1907, it also prevented a runaway market in 1901 and 1902. The Steel Corporation has in fact been a magnificent experiment in the effect of regulation of prices. It has brought to our most important industry that benefit so much desired by business men, steady markets. It has made possible the planning of construction long in advance with definite knowledge of costs. Mr. Good echoes the usual American opinion that in the conduct of its business the Steel Corporation, while a 'trust', deserves a place among the 'good trusts.' None the less, he emphasizes strongly that even this 'good trust' has been bad for its home country, and in view of frequent discussion of a possible copper merger, his reasons have peculiar interest for miners and metallurgists.

Briefly, the British critic blames the United States Steel

Corporation with the admitted failure of Americans to capture that share of the foreign trade which seems naturally to belong to them. This failure is reported in the one particular direction in which success was most surely anticipated. From 1900 to 1910 the iron and steel exports from Great Britain increased from 3,213,000 tons to 4,594,000, those of Germany from 838,000 to 4,868,000, those of the United States from 1,154,000 to 1,535,000. At present steel plants in Germany and Great Britain are working nearly to capacity, while of our own about one-third capacity is idle. This is true despite the fact that many at least of the idle furnaces are large modern stacks that would seem able to produce at as low working cost as any. It will be recalled that immediately before the Steel Corporation was formed, American costs of manufacture of iron and steel were below European and that the export business of the United States was increasing by leaps and bounds. In the past ten years the cost of pig iron and steel in the United States has, admittedly, increased rapidly. Just how much, is not altogether certain, but it is not necessary to take as literal truth the gloomy figures presented by manufacturers at the tariff hearings, to be sure that the margin of 1900 has largely disappeared. American furnaces can not compete successfully for the foreign trade because their costs of manufacture, instead of being lower than those of competitors, are now higher, and it is pertinent to ask why.

Into the cost of iron and steel, as of other materials, three factors enter: fixed charges, materials, and labor. When the Steel Corporation was formed it was heavily capitalized. The common stock quite frankly represented the hopes of the promoters, and much at least of the preferred stock represented the crystallized hopes of those already in the business. The bonds and some of the preferred stock represented existing values. It will be remembered that the immediate occasion for the formation of the company was the threat of Mr. Andrew Carnegie to parallel the Pennsylvania railroad. Another strong factor was the growing conviction of the steadier business men that means must be found for eliminating such manufacturers as the late John W. Gates, whose antics (and no other word accurately describes them) were a constant menace to business. Mr. J. P. Morgan and his associates took the easy and simple method of buying everybody off. Each man was given his price and turned loose to his own devices. That extravagant prices were paid is well known, and he knows but little of the history of affairs who can not point to properties which cost their owners thousands but for which the Corporation paid millions. The managers of the new enterprise had, therefore, a difficult load from the first. It has been contended that since the birth of the Corporation surplus earnings have been so successfully reinvested in plants, ore, and lands, that there is now solid value back of all the outstanding securities. Even if true, this merely emphasizes the fact that selling prices have been loaded to permit any such accumulation of profits. At home the Corporation has been able to hold prices at a level that permitted this. Abroad, where prices have been fixed by cost of manufacture, it has been at a disadvantage and American trade has suffered. Since the bulk of the sales of the Corporation have been domestic, there can be no escape from the conclusion that whatever value there is now behind the common stock of the Steel Corporation, has been created by the American people by payments in addition to a fair return on the actual money invested.

Materials as well as money enter into the production of iron and steel. When the Corporation was founded it was well supplied with furnaces, but it had only a moderate hold in the Lake Superior iron-ore districts. The first move was to increase the ore reserve. This was done so successfully that for several years now the Corporation has dominated the Lake Superior region, which, in turn, has dominated the iron-ore situation in the United States. In the main, purchases were plainly with a view to obtaining ore rather than forestalling competition. An exception, possibly, was the case of the Great Northern lands which were leased upon terms extremely favorable to the owners. Notice has recently been given that this lease is to be terminated, and a review of its terms and the history of ore production under the lease, indicates that Steel Corporation officials, in signing it, were not only unduly optimistic as to future business conditions, but probably influenced by fear of competition. At the time it seemed a wise or at least a necessary move. Conditions have, however, changed. The Lake Superior ores no longer completely dominate the situation. The seaboard furnaces, which ten years ago seemed likely to be pushed off into the ocean, have found satisfactory ores abroad at prices that permit them to compete on equal terms. High-grade Swedish ore is now delivered to Atlantic ports at 8 cents per unit, equivalent to 9 cents at the furnace, while this year the basis price of lower-grade non-bessemer ore from Lake Superior districts, delivered to Ohio and Pittsburg furnaces, was but a trifle below 8 cents. The Maryland Steel Company has drawn 54 per cent ore from the new Cuban fields at a cost that equals only 5 cents per unit, and it is possible that even this price may be lowered. At the same time the Southern furnaces and Southern ores are much more highly regarded than they were ten years ago. The Corporation, therefore, has not obtained quite the dominance that was anticipated from its heavy investments in iron-ore land.

That the general cost of materials has gone up in the last ten years needs no argument, and materials used by the Steel Corporation have afforded no exception to the general rule. What, possibly, is not recognized, is that the artificial prices of iron and steel products, first fixed to cover promoters' profits, have reacted to raise the price of practically everything else. If railways pay a large price for steel rails and equipment, they must exact a large price for transportation; and the cost of freight, often absurdly multiplied, enters into the selling price of every article of general consumption. The Steel Corporation, manifestly, can not be loaded with the whole sins of the community, and has been victim as well as villain, but it is our largest business organization and its influence in the matter is far from negligible. The major influence, after all, has been psychological. The sight of the millions 'cleaned up' by those who sold properties to the Corporation or who obtained promoters' profits, the constant and frank statement of large current profits, set everyone thinking of the desirability of going and doing likewise. Demands for higher wages could not well be denied when the cost of living had admittedly increased and profits were palpably high. With a high interest charge and increasing cost of materials and labor, the managers of the Steel Corporation have drifted into the position where prices must be maintained, and they have been holding aloft a huge umbrella under whose protection has crowded a multitude of smaller concerns. We believe it is the general opinion of business men that the United States Steel Corporation has been managed with signal ability along lines of the truest business statesmanship. It has been a generous buyer, a liberal employer, and a fair competitor. Its public statements have been frank and full. Criticism is directed not at the conduct of the enterprise, but at its promotion. Its history and present difficulties emphasize the fact that, in business as in other relations, peace may cost more than it is worth.

Mine and Mill of the Brakpan Mines, Ltd.

By H. S. Gieser and C. A. Tupper

In this article the description of the mine is due to H. S. Gieser, while C. A. Tupper has contributed to the description of the mill. The property of the Brakpan Mines Ltd. is situated on the far east Rand, 21 miles from Johannesburg. It consists of deep-level claims opened by two 7-compartment shafts 4400 ft. apart in the direction of the dip. The No. 1, or north shaft, is 3100 ft. deep vertically; No. 2, or the south shaft, is 3700 ft. deep, at which point the reef was intersected. An incline with an average grade of 7½° connects the two, and from this six levels are driven in both directions. Underground haulage in the incline is effected by means of an endless rope.

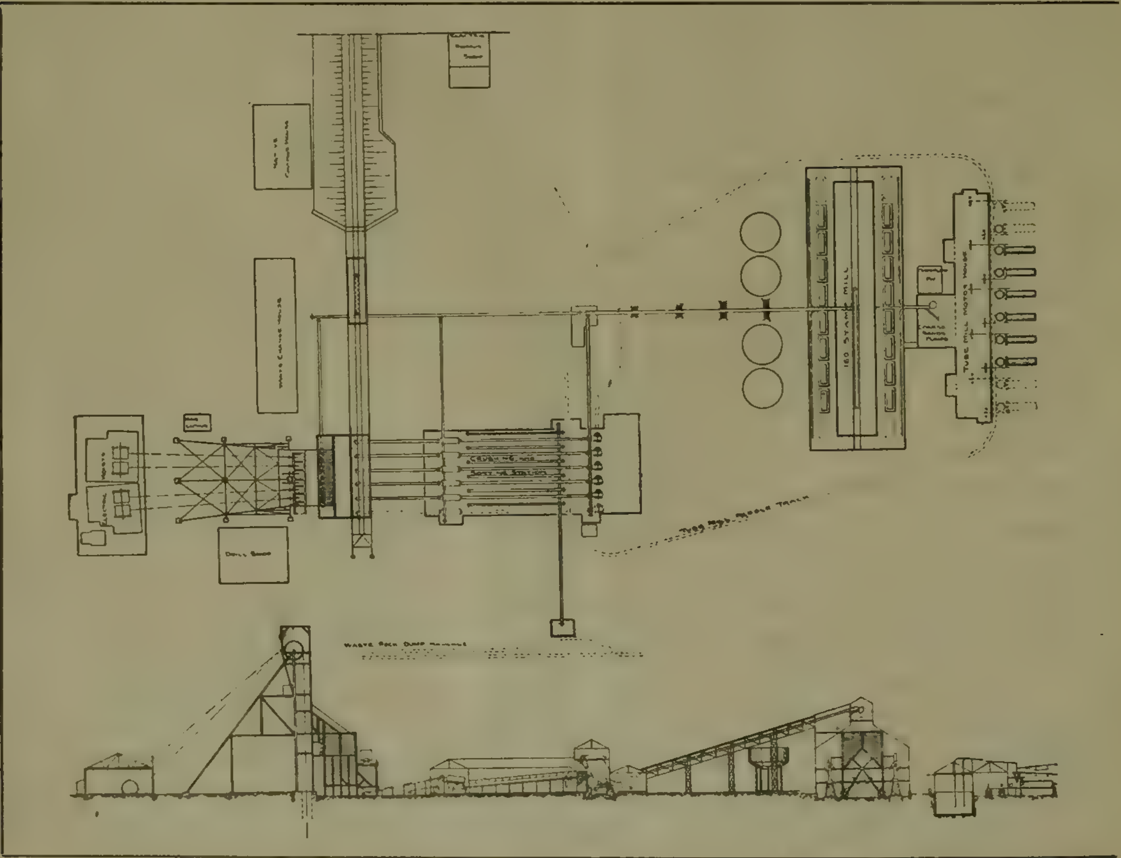
The electric power is purchased from the Victoria Falls & Transvaal Power Co., and is used throughout the plant, over 10,000 hp. being taken, distributed as follows: Main hoisting-engines, 4500 hp.; mine pumps, 1500 hp.; battery and tube-mills, 1950 hp.; reduction works pumping plant, 1000 hp. The remainder is used on the surface and for underground ventilation and haulage. All transmitting cables are paper-insulated, lead-covered, and armored, and are laid underground throughout, upward of 30,000 ft. having been placed. To a large extent they are laid on the ring system, thus preventing serious stoppage due to cable failure or damage. Power is metered to show the consumption for pumping, hoisting, milling, etc.; also, each pair of feeders is separately metered, enabling the supply to different departments to be closely checked.

The No. 2 shaft has 7 compartments, measuring 42 by 9 ft. over all. It is provided with a steel head-frame and is served by 2 electric hoists. One has parallel drums 11 ft. diameter and 8 ft. wide, and is grooved for 1½-in. rope. Tooth-clutches are provided for adjustment, also the standard type of liquid starter and automatic overhoisting prevention devices. The post brakes are applied by a dead weight relieved by air-operated cylinders with the ordinary cataract cylinder attachments. The second hoist, the main dimensions of which are the same as the other, is of the Ilgner system, with Ward-Leonard control, direct current, the motor generating-set being placed in a subdivision of the engine-room.

No. 1 shaft is equipped with a steel head-frame and a Ward-Leonard hoist similar to those erected at No. 2 shaft. All three hoists are 1500 hp. each and have a capacity of 100 tons per hour from a vertical depth of 3800 ft. The maximum hoisting speed is 3500 ft. per minute, and the average time for a complete trip is about two minutes.

The reduction plant has recently started operation, with 2,000,000 tons of 6.62 dwt. ore in reserve in the mine, where there is a stoping width of 55 in. Aside from pneumatic slime-agitation in Pachuca tanks, followed by vacuum filtration, with zinc-dust precipitation and subsequent filtration in Merrill presses, the features of interest include the following:

(1) Heavy stamps (2000-lb.), supplemented by eliminating screens at the back of the mortar-boxes; (2) multiplicity of service with the same centrifugal pumping units; (3) amalgamation following the tube-mill grinding only; (4) amplified and thorough classification, with simplified arrangements; (5) improved and simplified tube-mill feed; (6) sand treatment in accordance with the practice of separate collection, belt transfer, and the Blaisdell system of distribution in the treatment vats; (7) simple, direct, and efficient means of separating and conveying material; (8) aerial system of tailing disposal; (9) power consumption sep-



GENERAL ARRANGEMENT OF REDUCTION

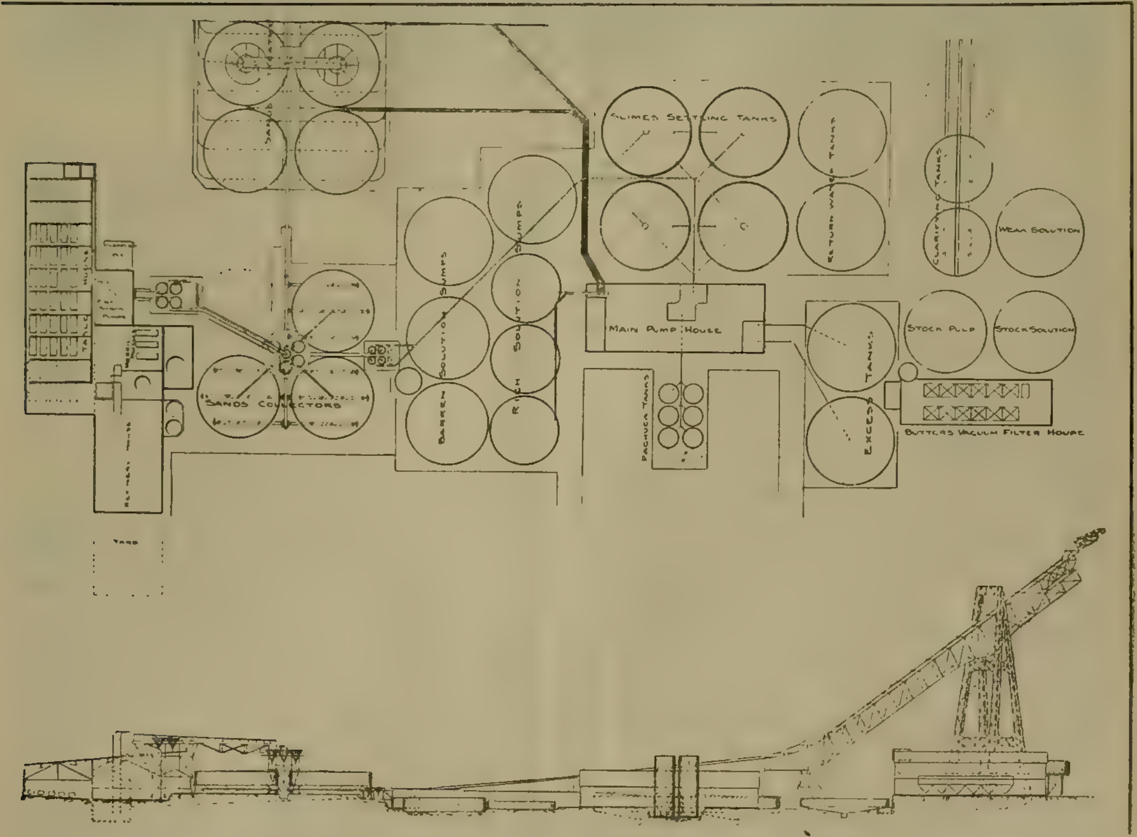
arately metered and kept relatively low throughout.

A surface tram runs from No. 1 shaft to No. 2, and delivery of ore, as hoisted, is all made at a point immediately adjacent to the latter. Here the fine ore from No. 2 is discharged into a hopper and thence to a conveyor to the mill, which is also fed from the fine-ore bin at No. 1.

PANORAMIC VIEW, BRAKPAN MINES PLANT.

The coarse ore from both shafts is dumped into a large holding bin. From this bin six parallel belts, five of which are in use, were provided for in the plans, to carry the material to the sorting and crushing plant, and each belt delivers its burden to a revolving trommel, whence the undersize falls to a feeder-belt of the mill-conveyor, and the reject passes to belts discharging to the crushers. From the latter, which are equipped with a dust removal system, the product is taken to the same mill conveyor carrying the fine ore from the shafts and the trommels. In the sorting shed are belts parallel with and slightly lower than the conveyors, upon which the waste rock is thrown, and these discharge at the end to a large belt-conveyor, running at right angles, which carries the waste to a bin, whence it can be hauled along the dump.

The main fine-ore conveyor, rising to the top of the mill, discharges on a transverse belt, extending the width of the 600-ton bin, which is provided with a tripper for evenly



PLANT, BRAKPAN MINES, LTD.

distributing the ore. From the bin the ore is delivered by suspended automatic feeders to 160 stamps, with heads 42 by $9\frac{1}{2}$ in. and stems $14\frac{1}{2}$ ft. by $4\frac{1}{2}$ in. The mortar-boxes are of the open-front type. The stamps weigh 2004 lb. each, of which 1076 lb. is in the head and shoe, and 928 lb. in the stem and tappets, and they are driven in groups of ten each. The stamps are arranged in two rows, with room at each end for an additional battery, the ultimate capacity of the mill to be 200 stamps.

The ore is crushed through a coarse eliminating-screen, at the back of the mortar-box, whence it is forced by two sand-gravel pumps (Robeson-Davidson) through pitch-lined launders to Caldecott diaphragm-cone classifiers or pulp thickeners. These deliver a product which contains only about 27% moisture. The spigot flow from the classifiers drops into steel hoppers, from each of which it passes to a Schmitt spiral tube-mill feeder. This is a feeder of a new type, originating on the Rand, which has already made a good record there. It is on the same general principle as the Pryce feeder, well known in South African practice, except that the pebbles for grinding in the mill may be fed in by belt, or in any continuous manner. It also permits lowering the classifier cone, and this enables the tube-mill to be erected with less allowance for head. Furthermore, the 'bayonet' joint of the older type is replaced by a plain flange. The feeder is lined with silex blocks, except in the outer ring or receiving drum, where a removable steel plate is used to prevent the sand from packing and retarding delivery of material to the spiral casing. The pebbles are selected in the sorting shed from pieces of a hard flinty substance forming part of the banket ore and are delivered in cars over a return track.

The plans of the mill, with 200 stamps erected, provide for 10 tube-mills, or one to every two batteries, but the initial installation consists of 6. These are $5\frac{1}{2}$ by 22-ft. Gates wet-grinding mills, 3 right-hand and 3 left-hand, made of heavy tank steel, with 6-in. silex lining. Manganese steel is used for the trunnion liners and ring liners of the feed end, and also for the discharge screen, these parts being the ones most subject to wear. In grinding, enough water is added to the contents to bring the moisture in the pulp up to 35%. Each machine is operated by spur gearing. This is placed at the outlet end to avoid the crowding together of the classifying, feeding, and driving arrangements at the head of the tube-mill. Each tube-mill discharges, through suitable launders, over five 5 by 12-ft. copper-plate tables, sloping 2.16 in. per foot. In the end of each table, and in the launder at the end of each set of 5 tables, is a cast-iron amalgam trap. The pulp from these plates flows to a sump, whence it is raised by Robeson-Davidson rotary pumps to return cone-classifiers, the overflow of which goes directly to the cyanide plant, while the spigot product is returned to two of the tube-mills for regrinding. The grinding machinery and accessories were erected under the supervision of Herbert Ainsworth, the South African representative of the Allis-Chalmers Co.

In the plans, allowance was made for four 60-ft. sand-collectors, three of which are now in service; and, by the interposition of suitable Caldecott cones, a relatively barren sand is delivered to them, the slime overflow being taken away through launders. Subsequently the remaining content of the sand is extracted as far as possible in 6 (of an eventual 10) treatment-vats, and the treated sand is discharged by hand into buckets, underneath the vats, of 22-cu. ft. capacity, holding about one ton, and automatically dumped by the Bleichert system of aerial sand haulage from the top of a cantilever (see illustrations), 210 ft. high, rising at an angle of 32°, driven by a 75-hp. motor. Adolf Bleichert & Co., of Leipzig and London, installed this system under a guarantee to dump sand at a cost not to exceed 3c. per ton. The buckets run on a monorail, are automatically attached to an endless rope, and can be dumped at any point on the circuit. The cantilever can be extended when the dump reaches the top.

The overflow from the sand collectors, and that from the cone-classifiers first above referred to, is re-treated in a third set of cones, the sand from which is returned to the collector cones. The slime is distributed to four settling-tanks and thence pumped to six Pachuca tanks, each 15 by 45 ft. After 4 hours agitation, the direction of the pump suction is reversed by by-passing and the valves in the pipe-line set so that the pulp flows to a stock-pulp tank. From the latter it is taken for treatment in a vacuum-filter plant of the Butters type. At this point there are placed the stock-solution tank, stock and surplus-pulp tanks, solution-storage tank, and others required in the system. There are two sets of Butters filter-boxes, each containing 6 sections of 28 leaves each, or a total of 336 leaves. Each leaf is 5 by 10 ft. A vacuum-pump draws the gold solution through the filter-frames.

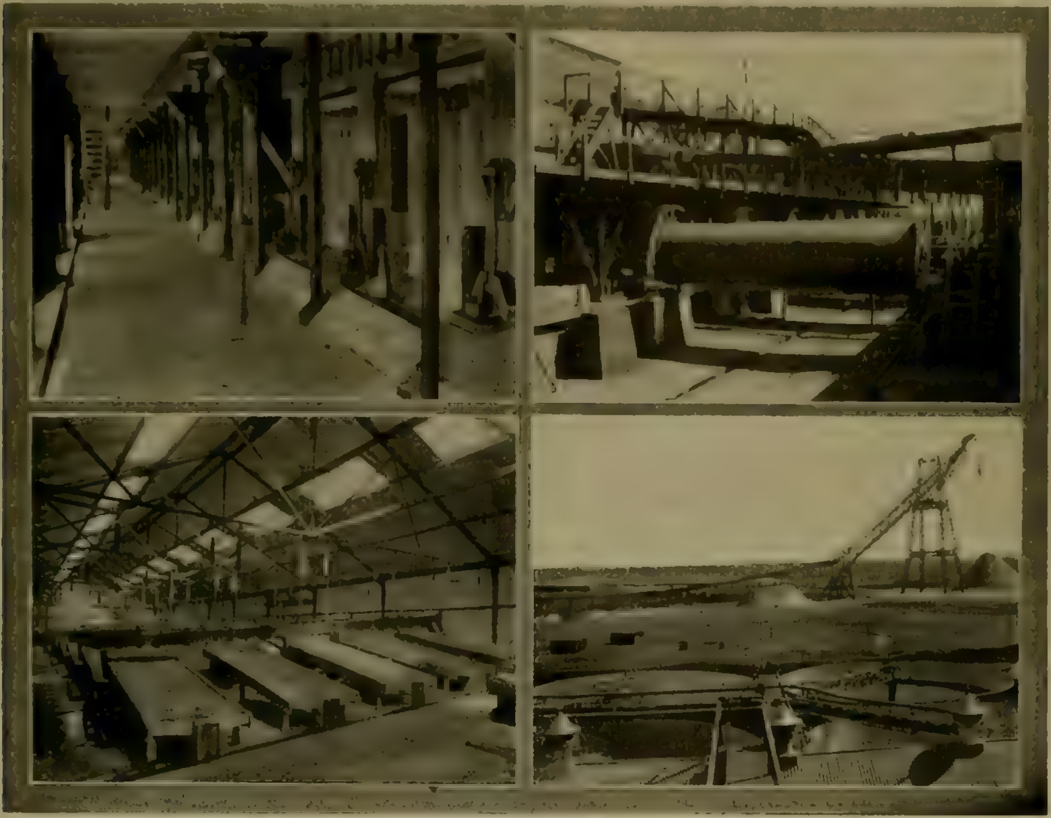
Two sand-filters, each used alternately, are provided for clarifying the solution from the Butters filter, which is then delivered to the gold-solution storage and afterward pumped to filter-presses in the refinery. As the solution is drawn off, zinc-dust emulsion is fed into it automatically and continuously. The filter-presses, of which there are three, each containing triangular frames, are of the type invented by C. W. Merrill, who first used the system when metallurgist for the Homestake mines, Lead, South Dakota. From these the gold-bearing zinc slime is conveyed to acid-vats and subjected to the customary treatment. Adjacent to the Merrill presses is the plant for recovering the gold from the amalgam and precipitate, and the apparatus for refining. The equipment includes, in part, a reverberatory-furnace capable of taking twenty No. 100 pots, and a calciner to take eight 3 by 2 by $\frac{1}{2}$-ft. trays. There are three barrels for black sand treatment, whence the product passes to a batea amalgamating-plate and 2 by 2 by $\frac{1}{2}$-ft. settling-bins. The amalgam from the batea is pressed in a couple of $4\frac{1}{2}$-in. presses, and sent finally to a set of standard Fraser & Chalmers retorts. It is a noteworthy feature that, in the construction and equipment of the entire plant for ore reduction, the estimates originally made by the engineer were closely approximated, an excess in any one direction having been balanced in another.

In June of this year, when over 2,000,000 tons of 'payable' ore and half as much lower-grade ore had been blocked out, with the levels 500 ft. apart and stoping well in progress on all except the 9th and 12th levels, the stamp-mill made a preliminary run of 18,133 tons, yielding 4310 oz. of fine gold, valued at £18,087, the low yield being due to the absorption by amalgamating-plates and in cyaniding usual to the starting of a new plant. The working costs, including all overhead burden and 1s. 6d. per ton milled for development, the same as for all figures given below, amounted to £20,936. An operating loss of £2849, therefore, resulted.

In the following month, July, the figures were as follows: 100 stamps and 3 tube-mills running; 27,906 tons of ore hoisted and 4626 tons taken from the dump, representing stoping and development; with waste sorted, 25,400 tons milled; fine gold recovered, 9594 oz., value £40,352, or 31s. 9d. per ton milled; working costs, 21s. 10d. per ton milled; profit, 9s. 11d. per ton milled. Owing to certain favoring conditions not likely to be duplicated in subsequent operations, this recovery was conservatively rated by the management as above normal. But in August the record again improved. The ore milled, with 100 stamps and as many of the tube-mills as required, running 25 days, was 35,051 tons; ore hoisted, 27,946 tons; ore from dump, 9401 tons; waste sorted; fine gold recovered, 12,149 oz., value £51,102, or 29s. 2d. per ton milled; costs, 17s. 5d. per ton milled; operating profit, 11s. 9d. per ton milled.

In September, with 100 stamps and 6 tube-mills in operation 28 days, 40,753 tons of ore was milled, as follows: ore hoisted, 38,173 tons; ore from dump, 9650; waste sorted; fine gold recovered, 13,139 oz., value £55,071, or 27s. per ton milled; operating costs, 16s. 10d. per ton milled; operating profit, 10s. 2d. per ton milled.

During October, with 100 stamps and 6 tube-mills in operation for 30 days, 42,089 tons of ore was milled, 43,176 tons having been hoisted, 6889 tons taken from the dump, and the waste sorted out. The fine gold recovered was 13,125 oz., valued at £55,070, or 26s. 2d. per ton milled. The operating costs were 16s. 7d. per ton, yielding a profit of 9s. 7d. per ton milled.



MORTAR BOXES. TUBE-MILLS.
PLATE HOUSE. TAILING STACKER.

The management of the Brakpan Mines, Ltd., is to be commended for the fact that, besides blocking out large ore reserves in advance of milling, it has apparently not attempted to make an impression of economy by niggardliness in expenditure. On the contrary, the construction and equipment all bears evidence of having been planned with a view to permanent investment, so far as any mining enterprise can be considered permanent. Building materials, for example, were mainly restricted to iron, steel, concrete, and brick. Furthermore, ample provision is made for repairs and maintenance, and for the welfare of employees, including a native compound and hospital, and the company bears its share in all work for the good of the district as a whole. It is also a member of the Consolidated Mines Selection Company's Recruiting Agency, and has been successful in obtaining a good grade of Kaffir labor. Among contributions made with other companies is one for the maintenance of the Miners' Phthisis Sanatorium.

For the excellent results already obtained credit is shared with F. L. Bosqui and W. L. Honnold, by their assistant, C. E. Knecht, J. F. Cook, consulting mechanical engineer, A. J. R. Atkins, mill superintendent, and especially the general manager, C. B. Brodigan, as well as others to whom supervision of the various details has been entrusted. When operating to its maximum capacity, as sufficient ore is mined, the plant will exceed the estimate of 60,000 tons per month originally made for it, particularly in so far as the stamps and tube-mills are concerned; and it is reasonable to believe, from the experience already had, that the remainder of the equipment will do its proportionate part.

The Colorado river discharges during an average year, into the Gulf of California 338,000,000 tons of mud and silt as suspended matter. In addition to this the dissolved substances in the water include 4,550,000 tons of sodium chloride, or common salt; 3,740,000 tons of sodium sulphate; 4,000,000 tons of lime; 2,400,000 tons of gypsum; and 4,800,000 tons of magnesium sulphate. In spite of all this dissolved material the Colorado at its mouth is not considered to be a stream of unusually high mineral content for that region of the country. The reason is that the river carries so enormous an amount of water that the dissolved salts constitute a comparatively small proportion of the total discharge. Other streams in the country contain dissolved salts in greater concentration; for example, Elm fork of the Red river, in Oklahoma, discharges nearly 1,300,000 tons of common salt annually. Although this amount is not so great as that discharged by the Colorado it is much greater in proportion to the size of the area drained. The discharge of salt from the Colorado is equal to 20 tons annually to each square mile drained by the river, but the salt in Elm fork of Red river is equal to 1680 tons per square mile of area drained. The same river discharges annually 177,000 tons of magnesium chloride, 168,000 tons of magnesium sulphate, 690,000 tons of gypsum, and 54,000 tons of lime. These quantities, too, are considerably greater than those carried in the Colorado in proportion to the size of the drainage area. The Belle Fourche river, at Belle Fourche, South Dakota, discharges 191,000 tons of gypsum, 79,000 tons of sodium sulphate, and 236,000 tons of magnesium sulphate. The mud and silt carried in suspension by this river amount to 1,100,000 tons. Milk river at Havre, Montana, discharges annually 41,000 tons of soda; Payette river, in Idaho, discharges 46,000 tons; Salt river at Roosevelt, Arizona, discharges 288,000 tons of salt and 170,000 tons of magnesium sulphate; and the Rio Grande 245,000 tons of lime and 386,000 tons of sodium sulphate.

The United States is the largest individual producer of lead in the world, with a total of 372,227 out of a world's output of 1,211,411 short tons.

The Mineral Land Laws of the United States

By James Douglas

*While the homestead laws continue to meet with popular approval, it is very generally recognized that the laws under which desert land, and those under which coal, mineral, timber, and stone lands can be secured, should be radically amended. These laws were all passed with the object of stimulating mining and quarrying, and encouraging the reclamation of the country's desert districts. Some of the measures erred in the direction of over-liberality, while others were framed to put, as it was hoped, the minerals as well as the land into the possession of the poor man, and prevent their being monopolized by wealthy corporations. But in every case the policy was to develop the natural resources as speedily as possible and induce population to enter. The policy, has succeeded so far beyond anticipation that if the legislators of a generation ago had been able to foresee the rapidity with which wealth would grow, and the national resources be proportionately used up, they might have hesitated to frame measures as generous as those which have attracted to the country the most enterprising spirits of all Europe, and to have afforded to men of magnificent powers of imagination and organization, aided by great wealth, the material for creating huge enterprises, which it is now found more difficult to control than it was to create.

In the colonies before the Revolution the title to the common minerals passed, under the common-law rule, to the owner of the soil, and the colonies, when they entered the Federation, retained control of these lands. But the mineral lands owned by the United States after the Revolution were disposed of under three statutes.

1. An Ordinance (May, 1785) entitled "An Ordinance for ascertaining the mode of disposing of lands in the Western Territory," which was of the vaguest character.
2. The Lode Law of 1866.
3. The General Mining Law of 1872, known as the law of the apex.

There was substantially no mining done in the United States till the purchase of Louisiana and the acquisition of the lead mines of Missouri, which had been one of the most alluring baits of Law's Mississippi scheme. As a result of the Louisiana purchase, a law was passed in 1807 to the effect that "the President of the United States shall be and is hereby authorized to lease any lead mine which has been or may hereafter be discovered in the Indian Territory for a period not exceeding five years." The leasing of mineral lands was entrusted to the War Department, but it did not impose on it a heavy burden till 1845, when, after the extinction of the Michigan Indian titles in 1843, active mining commenced in the native copper deposits of Lake Superior. For two years only, subsequently to 1845, the system of leasing was carried out. It was the system inherited from the mother country, but badly practised when applied on the large scale by inexperienced officials.

In his interesting address to the American Institute of Mining Engineers on 'A Century of Mining,' Abraham S. Hewitt† tells of the process by which the leasing system was supplanted by the out-and-out purchase system:

"For a few years the rents were paid with tolerable regularity, but after 1834, in consequence of the immense number of illegal entries of mineral land at the Wisconsin land office, the smelters and miners refused to make any further payments, and the Government was entirely unable to collect them. After much trouble and expense, it was, in 1847, finally concluded that the only way was to sell the mineral land, and do away with all reserves of lead or any other metal, since they had only been a source of continual embarrassment to the department.

"Meanwhile, by a forced construction (afterward declared invalid) of the same Act, hundreds of leases were granted to speculators in the Lake Superior copper region, which was from 1843 to 1846 the scene of wild and baseless excitement. The bubble burst during the latter year; the issue of permits and leases was suspended as illegal, and the Act of 1847, authorizing the sale of the mineral lands and a geological survey of the district, laid the foundation of a more substantial property."

It may be doubted whether reform of the working of the leasing system, instead of its abolition, would not have been a wiser course; but the radical step of alienating absolutely the mineral lands was recommended by President Polk on December 2, 1845, and enacted into law, and the copper lands of Michigan were offered for sale at $5 per acre, the price at which mineral lands have ever since been disposed of. The principal argument adduced by President Polk for the change of policy was the unprofitableness of leasing. He said:

"According to the official records, the amount of rents received by the Government for the years 1841, 1842, 1843, and 1844, was $6354.74, while the expense of the system during the same period, including salaries of the superintendents, agents, clerks, and incidental expenses, were $26,111.11, the income being less than one-fourth of the expense. To this pecuniary loss may be added the injury sustained by the public in consequence of the destruction of timber, and the careless and wasteful manner of working the mines."

But President Fillmore, in his annual message to Congress on December 2, 1849, referring to the application of the land laws to the newly-acquired territory of California, gives as the most logical reason for the out-and-out sale of the public lands, that "the relation of debtor and creditors between the citizens and the Government would be attended with many mischievous consequences." The public feeling in favor of actual ownership of land has always been strong.

The first mining excitement followed the first successful effort to mine the metallic copper of Lake Superior, and, as we have seen, the result was the adoption of the sale in preference to the lease system. The next modification of importance followed the rush for gold in California, then a remote area, newly acquired by conquest and subsequent treaty. To meet local exigencies, a mining code was framed by the miners, through methods curiously illustrative of the working of popular institutions.

When California was occupied by the United States the Mexican mining laws were in force, and till 1849 the conquered province remained under military rule. Colonel Mason, the governor, while still ignorant that the treaty of Guadaloupe Hidalgo had been signed on February 2, issued the following proclamation from Monterey on February 12, 1848:

"From and after this date the Mexican laws and customs now prevailing in California relative to the denouncement of mines are hereby abolished.

"The legality of the denouncements which have taken place, and the possession obtained under them since, till the occupation of the country by the United States forces, are questions which will be disposed of by the American Government after a definite treaty of peace shall have been established between the two Republics."

Without questioning the right of Colonel Mason to revoke arbitrarily the existing mining law, the miners obeyed, and framed rules and regulations, not only for regulating the conduct of mining, but for the mode of acquiring the mines themselves, although all of them were virtually trespassers on the public domain.

Hence arose the custom, afterward embodied in the United States statute, of allowing miners to create a mining district and constitute themselves into a legislative body, whose rules and regulations, if not contrary to either Federal or State or Territorial laws, have a binding obligation. These self-constituted legislators in California followed the Mexican code so far as it applied to discovery

---

*Excerpt from an address on 'The Industrial Progress of the United States,' delivered before the Royal Society of Arts, London, November 22.

†*Trans.* Amer. Inst. Min. Eng., V. 181.

and development, but they introduced into their mining code a principle which had no place in any modern mining statute. To them the ownership of the surface was subsidiary to that of the lode, or quartz vein, which might happen to crop out at any given spot. Therefore they conceded to the owner of the outcrop the right to follow his discovery to any depth, and under the 'dip, spur, and angle clause' of their amateur regulation, created extralateral rights and introduced the law of the apex, which came to be the distinguishing feature of the statutes passed in 1866 and 1872, and which has remained unaltered till today. This anomalous law of the apex was apparently copied from an old custom confined to the High Peak district of Derbyshire, and probably incorporated in the California mining code at the suggestion of some English miners. Judge Field, who was ultimately elevated to the Supreme Court of the United States, but who had been one of the pioneers of California—an *alcalde* before the admission of the State—a legislator in the first Assembly, and a State judge, thus graphically describes the process by which these mining regulations were framed by these early intelligent miners:

"The discovery of gold in California was followed, as is well known, by an immense immigration into the State, which increased its population within three or four years from a few thousand to several hundred thousand. The lands in which the precious metals were found belonged to the United States, and were unsurveyed and not open by law to occupation and settlement. Little was known of them further than that they were situated in the Sierra Nevada mountains. Into these mountains the emigrants in vast numbers penetrated, occupying the ravines, gulches, and canyons, and probing the earth in all directions for the precious metals. Wherever they went they carried with them that love of order and system and of fair dealing which are the prominent characteristics of our people. In every district which they occupied they framed certain rules for their government, by which the extent of the ground they could severally hold for mining was designated, their possessory right to such ground secured and enforced, and contests between them either avoided or determined. These rules bore a marked similarity, varying in several districts only according to the extent and character of the mines; distinct provision being made for different kinds of mining, such as placer mining, quartz mining, and mining in drifts and tunnels. *They all recognized discovery*, followed by appropriation, as the foundation of the possessor's title, and development by working as the condition of its retention. And they were so framed as to secure to all comers within practicable limits absolute equality of right and privilege in working the mines. Nothing but such equality would have been tolerated by the miners, who were emphatically the law-makers, as respects mining upon the public lands in the State. The first appropriator was everywhere held to have, within certain well defined limits, a better right than others to the claims taken up; and in all controversies, except as against the Government, he was regarded as the original owner, from whom title was to be traced. * * * These regulations and customs were appealed to in controversies in the State courts, and received their sanction; and properties to the value of many millions rested upon them. For eighteen years, from 1848 to 1866, the regulations and customs of miners, as enforced and molded by the courts and sanctioned by the legislation of the State, constituted the law governing property in mines and in water on the public mineral lands."

The Argonauts not only carried to the west coast the habits of self-government which were the heritage of the race, but carried them into practice with the same independence and originality as characterize most of the legislation of the colonists of Australia.

The rapid development of the Comstock Lode, after its discovery in 1859, rendered the framing of a Federal mining law a matter of necessity, and therefore in 1866 Congress enacted the first law under which a Federal title could be obtained to Federal mining land. The provisions of the Act are as vague as its title: "An Act granting the right of way to ditch and canal owners through the public lands, and for other purposes." Lindley says (I, p. 63):

"The title gives no clue to the scope of the Act. As a matter of fact, the title belonged to another Act which had passed the House, and for which the Mining Act was substituted in the Senate, without any attempt to change the title, and in this form passed both houses."

The Act provided:

"1. That all the mineral lands of the public domain should be free and open to exploration and occupation;

"2. The rights which had been acquired in these lands under a system of local rules, with the apparent acquiescence and sanction of the Government, should be recognized and confirmed;

"3. That titles to at least certain classes of mineral deposits or lands containing them might be ultimately obtained."

The Act, however, which is still in force is that passed in 1872 as "An Act to Promote the Development of the Mining Resources of the United States." The Act expresses decisively the liberality with which the country has disposed of its mineral lands, and the result has certainly justified its title and intent. The Preamble states:

"Be it enacted by the Senate and House of Representatives of the United States of America, in Congress assembled: 1. That all valuable mineral deposits in land belonging to the United States, both surveyed and unsurveyed, are hereby declared to be free and open to exploration and purchase, and the lands in which they are found to occupation and purchase, by citizens of the United States, and those who have declared their intention to become such, under regulations prescribed by law, and according to the local customs or rules of miners, in the several mining districts so far as the same are applicable and not inconsistent with the laws of the United States."

The extent of the mining claim is prescribed as follows:

"A mining claim located after the passage of this Act, whether located by one or more persons, may equal, but shall not exceed, one thousand five hundred feet in length along the vein or lode; but no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located. No claim shall extend more than three hundred feet on each side of the middle of the vein on the surface, nor shall any claim be limited, by any mining regulation, to less than twenty-five feet on each side of the middle of the vein at the surface, except where adverse rights existing at the passage of this Act shall render such limitation necessary. The end lines of each claim shall be parallel to each other."

The extralateral rights of the early California regulation are secured to the locator under the Federal law, under the third clause of the Act:

"That the locators of all mining locations heretofore made * * * shall have the exclusive right of possession and enjoyment of all the surface included within the lines of their locations and of all veins, lodes, or ledges, throughout their entire depth, the top or apex of which lies inside of such surface lines extended downward vertically, although such veins, lodes, or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side lines of the said surface locations; provided, that their right of possession to such outside parts of said veins or ledges shall be confined to such portions thereof as lie between the vertical planes drawn downward as aforesaid, through the end lines of their locations, so continued in their own direction that such planes will intersect such exterior parts of said veins or ledges. And provided, further, that nothing in this section shall authorize the locator or possessor of a vein or lode which extends, in its downward course, beyond the vertical lines of his claim, to enter upon the surface of a claim owned or possessed by another."

Whether granting these extralateral rights has advanced the progress of mining is a disputed question, but they have been the source of most protracted and costly litigation.

The Act prescribes the manner in which a mining claim must be monumented and recorded, and the amount of work which must be actually done upon it, either above or below ground per annum ($100 worth) in order to secure possessory rights. No rent or royalty is exacted by the Federal Government, but after $500 has been expended on the claim, the possessory title may be converted into an absolute patented title by payment of $5 per acre. The Act is admittedly defective in many of its provisions, but it would be foreign to my purpose to discuss its shortcomings. My object is to emphasize the motive which actuated the people, through their legislators, in throwing open all their lands, agricultural and mineral, not only to occupation, but to actual ownership by citizens or by anyone who has "declared his intention to become such." Under the Homestead Act the agricultural land is given freely; under the mining law no charge is made for the possessory title, and for a patent to a mining claim the trifling price of $5 per acre, hardly enough to meet the administration cost of the Land Department. Considering the incalculable hidden mineral wealth of the Western half of the continent, it is not to be wondered at if the active spirits of the world accepted the cordial invitation to share it on such liberal terms, and that it has been uncovered, developed, and marketed with such extraordinary speed, at extravagant profits to some, and that it has created spasms of speculative mania which have not had a healthy effect on public morals.

Mining companies are permitted the liberal allowance of 5000 acres, but if a company reaches its limit, the same shareholders simply organize another. Metal mining, therefore, on a large scale can be carried on without evasion of any law.

Most of the coal and iron is mined east of the Missouri, and possession therefore passed to the owners of the land. But the gold and silver, and most of the copper and lead, is produced in the Rocky Mountain States under the liberal Federal laws which we have described. The sum total in value for 1909, as given by the United States Geological Survey, is as follows:

Non-metallic products	$1,132,417,033
Metallic	753,427,290
Unclassified	300,000
	$1,886,144,323

The value of the metals in 1910 is given as $791,702,857.

Assuming the most modest estimate of actual profits on this large sum, we begin to appreciate the wealth that is accumulating in the country. Nor does this all fall to the lot of the shareholders of the large mining companies. If we take, for instance, the 2,000,000 acres of mineral lands which have been sold by the Federal Government, by far the largest proportion has been first located by prospectors and sold at often high figures. The poor man has been given the prospects, by the Federal Government, while the corporation has paid him the higher value of a promising though perhaps undeveloped holding. Comparatively little actual mining is done by the poor man. He avoids doing more than will give presumptive value to his claim, and even if it proves to be a claim which may develop into a mine, he obtains for it a high speculative return.

The Law of Co-ordination and the Cost of Delays

A surprising amount of the time of men and machines is spent, in almost any work of construction, waiting for something else to be done. The cause is improper co-ordination of work. While the law of co-ordination of work is not the first of the laws of management engineering, it is by no means the last. It may be seen from actual records how much waste time, delays waiting on some other construction operation may count into. Such a record is at hand in the latest report of the Isthmian Canal Commission. Besides giving the unit costs of all the major items of construction during the twelve months reported on, this report records the performance of several of the largest plant units employed. These records give the total time plant was under pay, the time consumed by delays of various sorts, and the output of work done per unit of time under pay and per unit of actual working time. A careful study of every item of these performance data will repay the labor.

From the records of delays it is seen that the total delays to plant and the delays due to 'waiting' were, in percentages of the total time the plant was under pay, as follows:

Purpose of plant:	Total delays, %	Delays waiting. %
Rock crushers, Porto Bello	27.34	7.10
Main mixing plant, Gatun	40.57	33.34
Auxiliary mixing plant, Gatun	40.57	37.86
Unloading cableways, Gatun	50.57	24.21
Unloading derricks, Gatun	50.92	26.24
Concrete placing cableways, Gatun	27.04	17.59
Rock crushers, Ancon	25.80	3.15
Sand unloading cranes, Balboa	29.41	26.14
Mixing cranes, Pedro Miguel	27.60	21.39
Mixing cranes, Miraflores	37.75	8.08
Concrete placing cranes, Pedro Miguel	32.56	23.15

Of the eleven plants recorded, only one was able to work more than three-quarters of the time it was under pay; two were not able to work half the time they were under pay. Delays of one sort or another consumed from 25.8 to 50.92% of the nominal working time of the plants recorded. Delays, waiting for some co-ordinate task to be performed, consumed from 3.15 to 37.86% of the nominal working time of these plants. In only three cases were delays waiting less than 10% of the time named, and in only four cases were they less than 20 per cent.

The vital significance of the figures quoted cannot be easily overlooked, but they nevertheless deserve emphasis. What has been the increased cost of concrete work at Panama, due to these delays? Probably no one can say exactly. No one, on the other hand, can doubt that it has been considerable. A cableway, or a derrick, or a concrete-mixer is not costing quite as much when waiting for work with steam up and the gang standing ready, as it is when actually carrying load, but the difference is not very great. Every stoppage of a mixer or cableway or any other tool under pay costs money and adds to the unit expense of production. It being true that delays increase the cost of production, then the converse is true that the elimination of delays decreases the cost of production. All delays cannot be eliminated. There will always be break-downs of machinery and stoppages from other unavoidable causes, and no series of construction operations can be so perfectly co-ordinated that there will not be some waiting of one on another. Good management, however, can reduce the number of delays due to almost any ordinary cause, and every reduction saves money.

The fact that is here shown to be true at Panama will be found to be true on almost any piece of construction work. Workmen and machines spend a considerable portion of their time waiting for something else to be done, or for materials with which to work. The various operations required are not in co-ordination. What are the causes of this lack of co-ordination? They are many; some of them are unavoidable, but most of them can be avoided entirely or in great measure. Lack of a carefully-drawn schedule of performance is one cause. There is no timetable to guide the performance of the various working units or to disclose when any unit is ahead of or behind time. Another cause is irregular arrival of materials and supplies to the workmen and machines. Failure to keep the plant in good repair, resulting in the break-down of a machine upon which workmen or other machines depend, is a third cause. Still another cause is improper quality of supplies, poor steel for the blacksmith, or poor coal for the boilers. The list of minor causes is much longer, but, like those named, they are ordinarily all susceptible of being in great measure eliminated.—*Engineering-Contracting.*

The Sinaloa Mining District

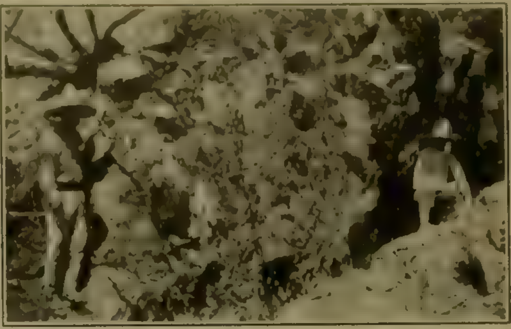
By G. L. Sheldon

The Sinaloa mining district is due south of the Fuerte and north of the Mocorito district, in the State of Sinaloa, Mexico. The county seat, Sinaloa, on the river of the same name, is an old town with a population of about 2000. Bamoa, a station on the Southern Pacific railroad Mexican system, about 14 miles south, and across the river, is the nearest railroad point. The western half of the district extends to the Gulf coast and is an agricultural area. The eastern half is in the foothills and Coast range section, extending to the Chihuahua State line, north and south from San Jose de Gracia.

STREET BOOTHS, SAN JOSE DE GRACIA.

At Bacubirito, 20 miles east of Sinaloa, the river makes a large bend, 6 to 8 miles long, and at the narrow neck, only about 300 yd. wide, the river bed, it is claimed, carries a good deal of placer gold. About twelve years ago considerable gold was taken from it, including numerous nuggets of good size, one of $4\frac{1}{2}$ lb. At the neck of a tunnel could be driven that would carry the water of the river during the low-water stage, and the bed below could be cleaned to bedrock. The tunnel would give a 70-ft. fall on the downstream side and generate a large amount of electric energy. A few years ago Messrs. Yard and Hughes did some work on the placer benches above the river, near Bacubirito, putting in a small pumping plant. Five years ago some Philadelphia people put up a small mill on a gold property near the river, between Bacubirito and Sinaloa. The San Jose de Gracia section is the principal one in the district that has received attention, because of the high gold content of its veins; this has been recently described in the *Mining and Scientific Press.*

Twelve to fifteen miles west and north of San Jose is an old silver district where several mines in past years have produced and shipped considerable high-grade silver ore. Ten years ago the San Jose mine was worked by an American, and some shipments of good ore were made, but the owner lacked capital to properly develop it. It is in a mountainous country. North and east of this, at Alisos, on San Jose creek, near its head, are several prospects carrying gold and silver. Thirty miles east of San Jose, near San Vicente on the river, during the past two years, a new discovery has been made. The vein is 30 to 40 ft. wide and shows a gold content of \$10 to \$50, with some copper; the vein can be traced several miles, and shows mineralization. Many locations have been made upon it, but so far it is but little developed. About ten miles above San Vicente, on the river near Torrogueno, Don Zarapo Lopez owns the Torrogueno gold property. This is 2000 ft., above the river in the andesite—a good 9-ft. quartz vein. Two years ago some Americans did some work upon it, but quit for want of funds, it is said. South from Torrogueno, near the divide between the districts of Sinaloa and Badirahuato, is the La Colorada mine, worked thirty years ago to a considerable extent. This is a 10 to 15-ft. vein carrying silver. Two years ago a waterspout completely covered the old works with débris, as it is in a small gulch. West of this and south down the river, on the east side, is a large limestone area which has many known prospects, mostly silver, with not sufficient development to demonstrate their value. In the vicinity of Bacubirito the veins contain mostly gold.



TORROGUENO VEIN, SINOLOA DISTRICT.

Northwest of Sinaloa, 12 or 15 miles, is Ocoroni, on the river of the same name, known above the Yecorato river. Four miles above this place is a lead-silver district which, while known for many years, has only received attention since the advent of the Southern Pacific railroad. Many claims have been located and considerable work done during the past year or two; for a distance of several miles there is a very good showing on a vein or veins, from 10 to 40 ft. wide, carrying 10 to 70% lead, good silver content, a little gold, and in some places zinc and copper. It was examined two years ago by an engineer who had several years' experience in the Coeur d'Alene in its early days, who thought the showing here was as good as that on the surface. It is only 20 miles by wagon-road from the station of Naranjos, on the Southern Pacific railroad, where it crosses the Ocoroni river. On account of its good transportation facilities and the urgent need of lead ores on the west coast for fluxing purposes, it is a promising lead district. Above it a few miles is an old silver-mining camp with ruins of old *haciendas*, where the ores were treated years ago. While the Sinaloa district is not as large as the Fuerte there is no doubt of its containing much good ore, and in time more than one producing mine will be opened.

SAN JOSE DE GRACIA MILL BEFORE ERECTION OF CYANIDE PLANT.

The San Jose de Gracia is probably the best small gold district in the State. The lower agricultural country is fully equal to the valley of the Fuerte, and with its rich silt soil probably surpasses it. There is abundance of water in the Sinaloa and Ocoroni rivers for irrigation purposes.

The world's production of zinc during 1910 was 883,419 short tons, and the consumption 882,573 short tons. In the United States the production was 269,184 short tons, and consumption 245,884 short tons.

Boyer Copper Deposits, Nevada

By Arthur Howe Carpenter

The Boyer property was located by Alva Boyer, a pioneer ranchman and prospector of Nevada. He has disposed of interests to others, but still retains the control. This deposit occurs near the contact of a flow of andesitic porphyry over an earlier mass of green andesite. The earlier mass is provisionally classified as 'melaphyre,' more in the sense of meaning black or dark porphyry, a use of the term proposed by Chamberlain and Salisbury. It is a dark greenish andesite with rather abundant white crystals of feldspar. Magnetite, augite, and olivine occur. The overlying eruptive was called an 'obscure trachyte' by Clarence King, whose Fortieth Parallel Survey passed over the property. Following the proposed scheme of classification, this might properly be called 'leucophyre.' It is not trachyte. It has a rough fracture, the ground-mass is even and uniform to the eye, and the only crystals certainly visible are clear tabular sanadine.

The contact lies flat, dipping about 20° to the northwest. The white porphyry is the base upon which the thick series of basalt flows make a long high table-land called Table mountain. These flows of basalt have the same dip as the contact, suggesting that the white andesite was intruded after the basalt flows, but the dip of these old lava beds is more probably due to faulting and folding. The mass of white porphyry outcrops for about four or five miles in an easterly direction, and the dark melaphyre outcrops below it for the same distance. There are a number of copper prospects along this contact and near it in addition to the Boyer group, which is near the west end, and some of these deposits near the eastern end might repay prospecting. Chalcopyrite and chalcocite intermingled occur, almost at the surface. However, on the Boyer, the deposits seem to be the strongest and most abundant. Near the eastern end of this white andesite belt the nickel and cobalt mines of Cottonwood canyon occur, which are described by F. L. Ransome on pp. 55 to 58 of Bulletin 414, U. S. Geological Survey. These mines attracted a great deal of attention thirty years ago by producing rich cobalt ores, which were shipped to Swansea. At the prices then paid, some of the ore brought over $1000 per ton. At either end these andesitic flows disappear against massive rhyolite hills and mountains, while several miles farther south a similar outcrop occurs with copper veins capped with pure hematite.

The main workings at present on the Boyer property are on Treasury Box hill, about 200 ft. below the contact and in the altered zone in the melaphyre. The copper was evidently deposited at the time of the eruption of the white andesite. The heat and steam accompanying this flow altered the upper two hundred feet of the underlying melaphyre, forming at the base of the altered zone a hard and impervious layer with a peculiar banded structure. This forms the foot-wall of the copper deposits, which lie in the 200 ft. of altered material above, and below the contact with the overlying andesite. In many places throughout the altered zone, small dikes of the white porphyry occur, shooting off from the main body. In places just above the contact, small iron-capped veins are seen coming up through the leucophyre. When followed these veins lead to massive chalcocite disseminated in a gangue of breccia, pieces of the pure black sulphides half as large as a man's hand having been occasionally found. Massive bornite, tenorite, and cuprite occur also, mixed with the two carbonates, melachite and azurite, making small rich deposits of ore. If followed, it is thought that these oreshoots will lead to the larger deposits that may lie at the contact and in the altered zone below it. At one place, from a deposit occurring at the surface (almost exactly at the contact), several large wagon-trains were loaded with rich copper sulphides and oxides, in 1861, and taken to Sacramento overland. The old shallow pits are still to be seen, surrounded with the piles of refuse, where was cobbed out the richer ore. Samples of these piles assay 29% copper. These rich ores carry 5 oz. of silver and traces of gold. Every other occurrence of copper ore on the property, when carefully assayed, seems to carry about 20c. gold per ton for every per cent of copper present.

The main work on Treasury Box hill was done in a bed of copper-bearing andesite about 100 ft. or more in thickness. The ore is chalcopyrite disseminated through the melaphyre, and the lower 30 ft. of the bed averages from samples obtained, wherever it has been opened, nearly 5% in copper and $1 in gold and traces of silver. Owing to lack of funds, it has been impossible to continue the development work as far as the contact, which dips in the direction the prospecting adits have been driven, but when this development work is done, interesting results may be obtained.

About a mile of the contact is included within the limits of the property, and throughout this distance it is possible to find ore in the altered zone in the melaphyre below the contact. At three other places besides on Treasury Box hill the surface indications are promising, and, in fact, at few of the well known copper properties of the West are the outcrops of copper-bearing rock more extensive. Large masses of carbonate ore exist assaying about 1.5% copper, and in places it is much richer.

The ground explored by the adit is badly faulted, so that it has not been possible to develop a continuous bed of ore, but it is thought that a bed of copper ore once existed over 100 ft. thick, 200 ft. wide, and, measured along the line of the dip, 500 ft. or more in length. Owing to the many faults, however, there are only blocks of ore lying at different levels, and not all of them have been opened. The dimensions given are simply the limits of the present exploratory work, and there is not so much ore actually developed. It is only possible ore. But there is reason to believe that the lower 30 to 50 ft. of each of these broken blocks will average over 4% copper. There is also reason to hope that the beds will continue down along the plane of the contact in the altered zone. The richer beds may be wider than this, but this is a matter of speculation. Naturally it is not thought that all of the altered zone beneath the contact is as rich in copper as this bed. The whole of it, however, seems to be copper-bearing, but most of it will be too low grade for profitable mining. Other beds will likely be found as rich and extensive as the one opened on Treasury Box hill, and the ore-bearing zone should continue as far down as the contact between the two porphyries and the beds of valuable ore prove strong and permanent. This ore zone lies so that several thousand feet of it, perhaps, underneath the white porphyry and back from the outcrop, could be prospected with churn-drills, though many of the holes farther back would have to go quite deep.

The ores are primary, and there is little or no secondary enrichment, nor has there been much chance for it. Large areas of the copper-bearing rock have been leached barren near the surface. The ground-water line does not seem to lie very deep now, however, and springs come to the surface in the contact and near it, and in places above it. In his general description of these properties Mr. Ransome refers to the occurrence of pyrite, but, so far as known to me, after a residence of nearly a year at the property, no pyrite occurs, all the sulphide ore consisting of chalcopyrite. This carries almost the theoretical content of copper, several pure specimens having been carefully analyzed. The general trend of the belt described by Ransome is the same as that described here, but it is not actually over 200 ft. wide.

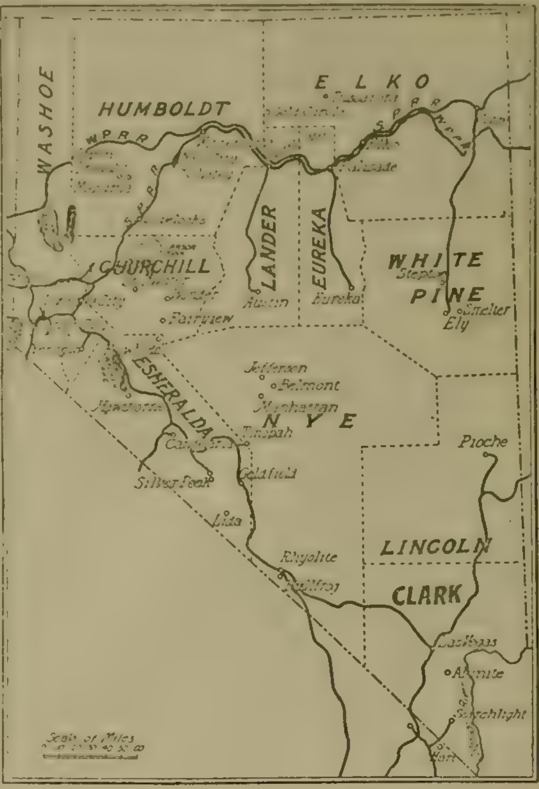
Chalcopyrite is hard to concentrate, as it slimes badly in crushing. Several concentration tests made with Wilfley tables, however, gave a recovery of 70 to 80% of concentrate assaying over 20% copper, which is high for such an ore. It is therefore apparent that no difficulties exist like those encountered at Yerington. The ore is an ideal one for oil flotation processes, and a test made with a laboratory machine gave the wonderful result of 92% recovery in concentrate assaying 30% copper.

There are over 1000 acres in the group [illegible] [illegible] in Dixie valley, two or three [illegible] [illegible] [illegible] sites are held. Plenty of water can be had in the flat or valley, and it is probable that [illegible] water can be developed. In the centre of the flat a number of springs come to the surface. In the next valley to the east, flowing artesian wells thirty years old exist. That valley is said to be 500 ft higher than Dixie valley, which is the lowest in Nevada, and, according to King, the point in front of the property is the lowest in the interior basin, so that water cannot get away. Everywhere in the centre of the flat water seems to stand permanently about 6 ft. below the surface. At the old borax plant, formerly operated there, they were not able to lower it below this point in a well, using a 4-in. triplex pump operated with a gasoline engine. The lower portion of this flat is occupied by the great Ossobb salt marsh, fully described by King. The whole valley is really a rock-bound lake, full of rock, silt, and clay of Quaternary times, and covered with the débris from the old lake floor. Water stands on the salt beds most of the year. The springs are fresh water. It is about 75 or 80 miles to either Battle Mountain or Winnemucca, both on the Southern Pacific railway. In going to either place there are no mountains or other barriers to cross. Winnemucca would probably make the better point for shipping and serving this section.

On Treasury Box hill about 500 ft. of work has been done, adits, drifts, raises, and winzes. Other parts of the group have received less attention. At one point about one-half mile north of the Treasury Box workings a shaft was put down into the melaphyre at the contact. They intended to drive from the bottom of this shaft back into the contact. This shaft cannot be explored now. It is supposed to be 170 ft. deep and passed through a bed of copper ore said to be 17 ft. thick, of oxides and carbonates. A sample taken from the ore piled on the dump assayed 15% copper with a little silver. The story among the local miners is that they actually drove toward the contact from the bottom of the shaft, but when they approached it, the ground got soft and, owing to the use of too few timbers, forty feet or more of the drift suddenly caved, becoming filled with decomposed rock, mud, and water. It is said that this water coming from the breast of the adit was greenish from copper salts, and that picks and shovels left standing in it became coated with metallic copper. An adit was then started farther down the hill to cut under the shaft and meet the contact lower. It was never finished, though about 800 ft. was driven. This could be cleaned out and driven through, but it was not laid out with any idea of future work and is on the wrong side of the hill, so that any ore developed would be inaccessible and costly to move. A shorter adit from the opposite side would cut the contact more quickly and develop more promising territory.

The property is a promising prospect. There is no large tonnage of ore blocked out at present. Probably 70,000 tons is all that can be counted as probable ore so far developed in the sulphide zone on Treasury Box hill, and much of this is low-grade concentrating ore. The adit through this zone averages 1.70% copper. This was driven at the time the porphyry copper mines were so fashionable, and this is a 'porphyry copper mine' in the sense that the gangue of the ore is an eruptive rock and the sulphides are disseminated through the rock. But it is chalcopyrite, not chalcocite, and while the grade compares well with the copper content of the ores at Ely and Bingham canyon, in America at least, no one has so far attempted to exploit primary ore deposits of this character. At present it is remote from railroads. However, local conditions are favorable for cheap mining operations, once a railroad reaches the district. There is reason to expect that the Southern Pacific company will build a line or 'cut-off' from Battle Mountain to Hazen through this valley. This will shorten the distance across Nevada by the present route 49.3 miles, but necessitates the construction of a long tunnel, about six miles. There would be no other mountain ranges to cross and an almost level grade can be had. The estimated cost of this construction is much less than the cost of the Lucin 'cut-off' across Salt Lake, and the distance saved would be much greater.

The copper belt of the Piute range of mountains is about ten miles long and a number of other prospects occur north or south. On one group a vein or deposit outcrops about 100 ft wide. An adit has been driven to cut this, but, so far, has only entered the foot wall. The breast of the adit is in decomposed rock, badly stained with iron oxide. It will cut the vein about 200 ft. below its outcrop, and, I believe, will open a valuable deposit. There are a number of veins or zones extending the whole length of the ten miles, easily noticeable from a distance out on the flat, on cloudy days, as dark bands along the mountains. These are siliceous irony outcrops, 50 to 100 ft. wide, and the zone in which they occur is 2000 or 3000 ft. wide. Whenever closely examined, copper sulphide, oxide, and carbonates are found, and it is likely that important deposits of copper will be discovered below. However, the ore of this region is chalcopyrite, and, until the secondary ores of Bingham, Ely, and the great Arizona 'porphyry' copper mines become scarcer, it is not likely that attention will be turned to these primary ores. But, sooner or later, the disseminated chalcopyrite ores that occur in large masses will attract attention, and it is from these deposits that future copper supplies of the world will be drawn. When that time comes, with the advent of a railroad, this region will become a copper producer of no mean importance.



MAP OF WESTERN NEVADA.

THE Straits Settlements Land Office returns show that during 1910 the area alienated for mining in Perak amounted to 10,464 acres. These figures show a considerable advance on those of the preceding year. There was some activity in mining in the Kinta district. In face, however, of the increased area alienated for mining in the year, the total area held under mining titles is said to have been reduced by about 3000 acres; the labor conditions have been enforced with some stringency, and there have been fairly numerous applications for the conversion of mining titles into agricultural.

Deterioration and Spontaneous Heating of Coal in Storage

By Horace C. Porter and F. K. Ovitz

[*]Not many years ago, coal was commonly regarded as an extremely unstable material, subject to very serious alteration and losses on exposure to the elements. The 1889 edition of Groves & Thorp's 'Chemical Technology of Fuels' says: "In some places coal is known to lose 50% of its heating value in six months." Other statements like this are to be found in recent literature, but probably the great majority of chemists and engineers today hold no such exaggerated ideas on the subject. There is, on the other hand, a well defined suspicion, in the minds of many, that sufficient loss of volatile matter and sufficient deterioration by oxidation does occur in coal to be of industrial importance; and for that reason the investigations described in this paper were undertaken, by the Bureau of Mines, to determine accurately the extent of the deterioration in different types of coal. First, a study was made in the laboratory of the loss of volatile matter from crushed coal during storage. The results of these experiments have been published in Technical Paper No. 2, Bureau of Mines, entitled 'The Escape of Gas from Coal,' and will therefore not be given here in detail. Suffice it to say that while several coals evolve methane in large volume, especially in the early period after mining, the coal suffered in one year a loss in calorific value from this cause of but 0.16% as a maximum. It seems, therefore, that the loss due to escape of volatile matter from coal has been greatly overestimated.

At the instance of the Navy Department, however, which is a purchaser of coal to the extent of two or three million dollars annually, and stores large lots in warm climates for long periods of time, more elaborate tests were undertaken to determine the total loss possible in high-grade coal by weathering. The extent of the saving to be accomplished by water submergence as compared to open-air storage was a point to be settled, and there had also arisen the question as to whether salt water possessed any peculiar advantage over fresh water for this purpose. Coal-storage problems have assumed importance during the past few years on account of the uncertainties of supply due to strikes and transportation difficulties. The naval coaling-stations, the Panama Railroad Co., the commercial coal-distributing companies of the Great Lakes, large coke and gas or power plants at a distance from the coalfields, and the railroads themselves, particularly those in the West, keep 50,000 to 500,000 tons in storage a large part of the time.

In brief outline, the tests by the Bureau were carried out as follows: Four kinds of coal were chosen: New River, on account of its large use by the Navy; Pocahontas, as a widely used steaming and coking coal in the Eastern section and as being also the principal fuel used in the Panama Canal work; Pittsburg coal, as a type of rich coking and gas coal; and Sheridan, Wyoming, sub-bituminous, or 'black lignite', a type much used in the West. Every test portion was sampled each time in duplicate. Moisture, ash, sulphur, and calorific value determinations were made on each sample, the last by means of the Mahler bomb calorimeter and a carefully calibrated Beckman thermometer. All the calorific values in the tables have been calculated to a comparable unit basis.

The results show in the case of the New River coal less than 1% loss of calorific value in one year by weathering in the open. There was found practically no loss in the submerged samples, and fresh water seemed to 'preserve the virtues' of the coal as well as salt water. There was almost no slacking of lump in the run-of-mine samples, and the crushed coal, in all cases, deteriorated more rapidly than run-of-mine. The Pocahontas run-of-mine, in a 120-ton pile on the Isthmus of Panama, lost during one year's outdoor weathering 0.4% in heating value, and suffered little or no physical deterioration of lumps. The Pittsburg gas coal, during six months outdoor exposure, suffered no loss whatever of calorific value, measurable by the calorimetric method used—not even in the upper surface layer of the bins.

The Wyoming coal lost as much as 5.3% in one of the bins during 2¾ years, and 3.5% even in the first three months. There was bad slacking and crumbling of the lumps on the surface of the piles, but where the surface was fully exposed to the weather this slacking did not penetrate more than 12 to 18 inches in the 2¾-year period.

No outdoor weathering tests have been made by the Bureau on coal of the Illinois type. Thorough tests, however, on this type have been reported by S. W. Parr, of the University of Illinois, and by A. Bement of Chicago, both of whom find from 1 to 3% calorific loss in a year by weathering. Mr. Bement reports a slacking of lumps (in tests on small supplies) of over 80% in one case and about 12% in another. It is probable that in this type, as in the Wyoming, the slacking in a large pile would not penetrate far from the surface.

Storage under water unquestionably preserves the heating value and the physical strength of coal. But it practically necessitates firing wet coal, and therefore means the evaporating in the furnace of an amount of moisture varying from 1 to 15%, according to the kind of coal. This factor is an important drawback to under-water storage with coals like the Illinois and Wyoming types, which mechanically retain 5 to 15% of water after draining, but in case of the high-grade Eastern coals, if firemen are permitted, as is ordinarily the case, to wet down their coal before firing, "so as to make," as they say, "a hotter fire," then the addition during storage of the 2 or 3% moisture which these coals retain would be of little consequence. Submergence storage is an absolute preventive of spontaneous combustion, and on that account alone its use may be justified with some coals, but merely for the sake of the saving to be secured by avoidance of weathering, there does not seem to be good ground for its use.

Losses in coal due to spontaneous heating are a much more serious matter. Oxidation, probably in the main an absorption of oxygen by the unsaturated chemical compounds in the coal substance, begins at ordinary temperature in any coal, attacking the surfaces of the particles, thus slowly developing heat. In a small mass of coal this slowly developed heat can readily dissipate itself by radiation, and no rise in temperature results. If radiation is restricted, as in a large pile densely packed, the temperature slowly rises. Now, the curve of oxidation rate, plotted against temperature, rises with great rapidity; and when the storage conditions are such as to allow a certain point (near 100°C.) to be passed, the rate of oxidation is great enough ordinarily so that the heat developed overbalances the heat radiated, and the temperature will rise to the ignition point if the air supply is adequate. The importance, therefore, can be seen of guarding against even moderate heating in the coal, either from internal spontaneous causes or by radiation from external sources. Increased loss of heating value and of volatile matter occurs at moderately increased temperatures, even though the ignition point is not reached.

The amount of surface exposed to oxidation in a given mass depends on the size of the particles and increases rapidly as the fineness approaches that of dust. Dust is therefore a dangerous thing in a coal pile, particularly if it is mixed with larger-sized coal which form air passages to the interior. Spontaneous combustion is brought about by slow oxidation in an air supply sufficient to support the oxidation but insufficient to carry away all the heat formed. There is a wide variation among coals in friability. In comparative rattler tests under certain standard conditions, Pocahontas, New River, and Cambria county, Pennsylvania, coals produced nearly twice as much dust (through ⅛-in. screen) as a sample from the Pittsburg bed. This is a large factor in spontaneous combustion. Mixed lump and fine, that is, run-of-mine, with a large percentage of dust, and piled so as to admit to the interior a limited supply of air, make ideal conditions for spontaneous heating.

---

[*] Presented, by permission of the Director, Bureau of Mines, at a joint meeting of the New York sections, Amer. Chem. Soc., Amer. Electrochem. Soc., and the Soc. of Chem. Ind., New York, November 10, 1911.

High volatile matter does not of itself increase the liability to spontaneous heating. A recent circular letter of inquiry on spontaneous combustion sent by the Bureau to more than 2000 large coal consumers of the United States has brought 1200 replies, of which 260 report instances of spontaneous combustion, 220 of them naming the coal. Of these 220, 95 referred to semi-bituminous low volatile coals of the Appalachian region, and 55 to Western and Middle Western coals. This result shows at least no falling behind on the part of the 'smokeless' type and no cause for placing special confidence in these coals for safety in storage.

A serious fire in cinder-filling under a manufacturing plant in Pittsburg was recently investigated by the Bureau, and all evidence pointed to spontaneous combustion as the cause, induced by external heat radiated from a furnace. The cinders contained 40% carbon. A similar fire occurred two years ago in cinder-filling under a smelting plant on Staten Island, in which case the cinders contained 33% carbon. Damage amounting to $20,000 was done. The cause was not definitely determined, but from the reports of the insurance adjusters, spontaneous heating appears to be the most plausible explanation. The volatile matter in the material could not have been a factor in these cases.

Pocahontas coal gives a great deal of trouble from spontaneous fires in the large storage piles at Panama. It is reported also by several large by-product coke concerns to be more troublesome in this respect than their high-volatile gas coals. The high-volatile coals of the West are, to be sure, usually liable to spontaneous heating, but they owe this property to chemical nature of the substances which compose the coal, rather than to the amount of volatile matter. Strange as it may seem, a high oxygen content in coal appears to parallel its avidity for oxygen and to promote, therefore, its tendency to spontaneous combustion.

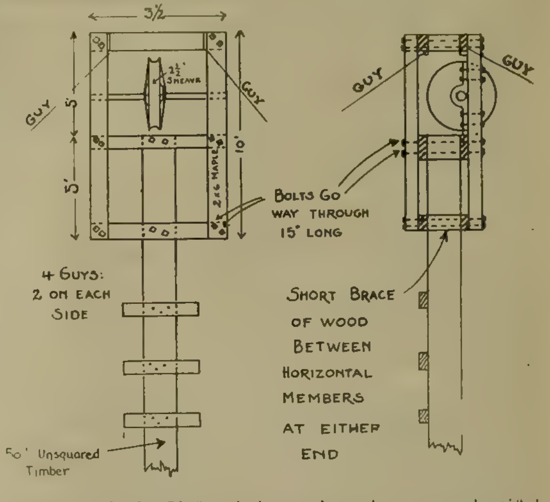
The influence of moisture and that of sulphur upon spontaneous heating of coal are mooted questions much discussed, not much actually investigated, and certainly not yet settled. Richters has shown that, in the laboratory, dry coal oxidizes more rapidly than moist, but the weight of opinion among practical users of coal is that moisture promotes spontaneous heating. The observation by the Bureau of many actual cases has not developed any instances where moisture could be proved to have had such an effect. Sulphur, on the other hand, has been shown by these investigations to have, in most cases, only a minor influence. In a number of actual cases, samples of the heated coal from areas where the heat was greatest have been analyzed, both for the total sulphur and that in the sulphate form. The difference between these—or, in other words, the unoxidized sulphur—was in no case less than 75% of the average total sulphur in the original. In other words, not more than 25% of the total sulphur has entered into any heat-producing reaction. The possibility remains, however, that all of the sulphur which was oxidized was concentrated in one pocket of moist flaky pyrite, and thus sufficient heat was developed in one spot to act as an igniter. On the other hand, a Boston company, using Dominion (Nova Scotia) coal of 3 to 4% sulphur, has much trouble with spontaneous fires in storage, but a number of samples taken by the Bureau from exposed piles of this coal in which heating had occurred showed that 90% of the sulphur was still unoxidized. Experiments in the laboratory, passing air over coal at 120°C. has developed enough heat to ignite the coal and no change was found in the form of the sulphur. While not entirely conclusive, these results point to a very minor contribution, if any, on the part of sulphur to spontaneous heating in coal.

Freshly mined coal, and even fresh surfaces exposed by crushing lump coal, exhibit a remarkable avidity for oxygen, but after a time become coated with oxidized material —'seasoned', as it were—so that the action of the air becomes much less vigorous. It is found in practice that if coal which has been stored for six weeks or two months and has even become already somewhat heated, be rehandled and thoroughly cooled by the air, spontaneous heating rarely begins again. A large power plant in New York crushes its coal to pass a 4-in. screen immediately after unloading from barges, the fine coal and dust, 50%, or more, being left in the coal to be stored. This freshly crushed coal is elevated to iron hopper-shaped bunkers directly over the boilers, and the air temperature in these often reaches 100°F. As the coal hangs on the sloping sides sometimes three or four months at a time, it seems hardly surprising that some of the bunkers are on fire practically all of the time.

With full appreciation of the fact that any or all of the following recommendations may under certain conditions be found impracticable, they are offered as being advisable precautions for safety in storing coal whenever their use does not involve an unreasonable expense: (1) Do not pile over 12 ft. deep, nor so that any point in the interior will be over 10 ft. from an air-cooled surface. (2) If possible, store only lump. (3) Keep dust out as much as possible; therefore reduce handling to a minimum. (4) Pile so that lump and fine are distributed as evenly as possible—not, as is often done, allowing lumps to roll down from a peak and form air passages at the bottom. (5) Rehandle and screen after two months. (6) Keep away external sources of heat, even though moderate in degree. (7) Allow six weeks' 'seasoning' after mining before storing. (8) Avoid alternate wetting and drying. (9) Avoid admission of air to interior of pile through interstices around foreign objects such as timbers or irregular brick-work; also through porous bottoms such as coarse cinders. (10) Do not try to ventilate by pipes, as often more harm is done than good.

Simple Sheave Stand

The accompanying sketch shows a simple sheave-stand for the hoisting-cable between engine-house and head-frame. It is much cheaper for a small plant to erect such a support on a single 50-ft. timber, where logs are plentiful, and to hold it in place by guy-wires, than to build the elaborate self-supporting structure of the four-post design. The bottom is set in a hole dug three or four feet deep, and the timber raised by block and tackle. This design is used in the Lake Superior iron region at a mine which hoists a three-ton skip from 700-ft. depth.



The Biggenden bismuth mine, Queensland, treated 478 tons of ore during the quarter ended September 30, yielding 10.67 tons of bismuth sulphide. The value of the metal content, after allowing for a 10% loss in the process of reduction, with bismuth at 7s. 6d. per pound, is £1043. The ore now being handled contains less arsenic than previously, thus giving a better product, and enabling a lower grade ore to be profitably treated.

Subsidizing Prospecting

By Walter A. Koch

The citizens of Colorado have resorted to an unusual but apparently sensible expedient to rehabilitate the State's metal-mining industries. They have sought to bring the mining industry in Colorado back to the prosperous plane of ten years ago by sending out into the hills prospectors, supported by public subscriptions, to search for new deposits of mineral. In the early part of this year the commercial organizations of Denver began an earnest inquiry into the causes of the decline in Colorado's metal production, and the consequent lessening of the number of men employed in the mines and mills; these circumstances having a most important bearing upon business conditions in Denver. Figures published by the State Bureau of Mines and the U. S. Geological Survey indicated that the production of metals in the State had decreased from a little over $50,000,000 in 1900 to $33,000,000 in 1910—a loss of about 33%. The gold output alone decreased from nearly $29,000,000 to $20,297,000 within the decade.

This condition forced itself so heavily upon the attention of the citizens of Denver and the State that public meetings were held to discuss means for rejuvenating the State's best known industry. Columns of newspaper comment were offered by mining men, journalists, and business men. While many theories as to the decline in metal production had been advanced, it was a generally accepted belief that it was due to the fact that during late years but little prospecting has been going on in the hills, and that mines in the development and even the producing stage have greatly lessened their exploration for new orebodies. This was attributed to the tightness of the money market, to the restrictions of the Forest Service, which were alleged to have had a deterrent effect upon prospecting within forest reserves, and to the undue exactions of the 'smelter trust' in ore treatment. At the same time the people of the State were hoping, and with great confidence, that a new mining district would be found. The daily newspapers teemed with stories suggesting that the mountains of the State harbored many still undiscovered Cripple Creeks. One of such, if developed, would bring the excitement that would furnish a great stimulus to industry in all parts of the State.

The Denver *Republican* advocated the idea of raising by popular subscription a fund sufficient to send prospecting parties out on a search for minerals, during the summer. The plan was accepted by the Denver Chamber of Commerce, coöperating with other commercial bodies, and funds for such a purpose were solicited. A 'Grubstake Committee' empowered to make contracts with prospectors and furnish the necessary supplies for the season, was appointed. Last May the movement was put under way. The season of prospecting under the auspices of the Denver Chamber of Commerce was to end on December 1. The committee, composed entirely of experienced mine operators and engineers, gave close attention to the work during the entire time. The prospectors were chosen with great care and were fully instructed as to what districts to prospect and how to proceed with locations and discovery work. It was intended to be a campaign of scientific surface prospecting. At the close of the season the committee carefully reviewed the work done, and in a report just issued it has pronounced the experiment a success, expressing at the same time the belief that much good to the State's mining industry would result. The following is taken from the committee report:

During the season 34 prospecting parties, comprising in all 53 men, were sent out on prospecting tours, with supplies furnished by the committee. The money raised for the campaign amounted to $9215. Of this amount, $7400 was expended in the work, at the rate of $250 per party or $160 per man. The committee was very fortunate in selecting the men, there having been few disappointments from this source. The number of locations made was 43, and on each location the usual discovery shafts were put down. In eleven of these, good ore was discovered in 10-ft. holes, the assays going as high as $1000 per ton. In the opinion of the committee, these are unusually good prospects, and easily warrant further development. The contracts with the prospectors provided that all locations were to be made jointly in the name of the Chamber of Commerce and the individual prospector; both being equal owners in the claims.

The committee, in a preliminary report, recommended the organization of a development company to exploit the claims considered to have sufficient mineral showing. As a result the Colorado Grubstake & Mining Co. was formed, with a capital of $250,000, shares $1 each, to assume charge of the development. The Chamber of Commerce is to receive $25,000 of the capital stock for 'fathering' the enterprise; the contributors to the grubstake fund are to receive full-paid stock at par value in amounts equal to their contributions, and the remainder will be sold at par to raise funds for development.

Without question, many Colorado citizens will subscribe for the stock, and it is not considered that there will be much difficulty in raising money. The provision is made that the entire proceeds of stock sales are to be expended in actual development, all officers in the company contributing, for the present, their services. The men identified with the management of the development company include Phillip Argall, Ernest LeNeve Foster, R. D. George, V. C. Alderson, G. Montague Butler, F. W. Traphagen, George W. Schneider, Thomas Tonge, and Henry C. Beeler.

The feeling generally prevails among leading mining men that the results of this attempt to stimulate metal mining activity have already justified the efforts put forth. The agitation has attracted capital to many legitimate and worthy enterprises, and mining activity throughout the State, due to this or other reasons, has been decidedly increased. All districts have felt an impetus from this Statewide attempt to promote Colorado's mining interests. Just what success will attend the efforts of the Colorado Grubstake & Mining Co. in operating the claims located by its prospectors remains to be seen, but the directors of that enterprise, in raising money for the work, are prepared to hold out the representation to intending purchasers of stock that they will get the fairest 'run for their money' that the mining industry can afford, so far as a venture of that kind is concerned.

Mining Possibilities Near Constantinople

On the railroad line Panderma-Balikessir-Sousourlok-Soma, for which the concession has recently been granted, about 71 kilometres distant from the harbor of Panderma, is found the antimony mine of Demir Kapou, near the village of the same name. The concession extends over an area of about three thousand acres and includes four veins of considerable strength. The region is not being worked at present, owing to a lack of capital.

Another mine on the Asiatic coast of the Sea of Marmara is the argentiferous lead mine of Kara-Dagh. It is situated in the *caza* of Bigha, about 40 kilometres distant from Kara-Bigha, which has excellent harbor facilities. This mine is said to be one of the best of its kind in Turkey. The former proprietor made attempts at exploitation at three points. Dodja, Kodja-Kavouchlar, and Gumuch-Acheka, but finally limited his efforts to the last named. This mine was successfully worked in former times, but was abandoned fifteen years ago, after the crumbling in of the earth, which destroyed the entire plant. It is thought, however, that the work might be taken up again and be carried at this point to a depth of 20 or 30 metres and for a length of 600 metres. The mine has several shafts and drifts. Transportation facilities to the place of embarkation at Kara-Bigha are not difficult and wagons carrying 750 kg., drawn by buffalo, make this trip in a day, at a charge of 50 piastres. The entire expenses to the ship, including lading and storage, amount to about 17 francs per ton.—*Levant Trade Review*.

Shifting a Bucket Dredge

A short description of the method adopted by the Stanthorpe Proprietary Dredging Co. in removing its bucket dredge at Emmaville, New South Wales, to another dredging site, given by a correspondent of the *Australian Mining Standard*, will prove of interest.

The distance the dredge had to be moved was about half a mile. There was a choice of three methods: (1) to dismantle the dredge and transport it piece by piece; (2) to arrive at a satisfactory arrangement with the Great Britain Co. to work through its ground, which lies between the other company's property; and (3) to shift the dredge as a whole, along dry land, by means of its own power. Of these, the second method might possibly have proved the most economical, but the third was adopted, and the fact that the method is unique is the excuse for the description.

Operations were started about July 15, 1911, and the dredge successfully reached the site at the beginning of November. Calking operations have been started, which will take about a fortnight to complete. The buckets and tumblers were removed from the dredge for separate transport, but otherwise the barge was left intact. A track was roughly prepared along the hillside for the dredge to travel along. Trenches were then dug some twenty yards ahead, and headers put in. Wire ropes, with a suitable arrangement of pulleys, were fastened to the gantry framing of the dredge, taken out and passed around and connected to the head logs, and thence back to the main hauling winch of the dredge. The barge itself was run on skids about 10 by 10-in. hardwood, placed approximately 2 ft. apart. When these were laid in position the pull was commenced, when, all going well, the dredge began to move. Great difficulties were encountered at first. The inclines from the dam to the road were very steep. Headers were not used at first, but trees and stumps were utilized instead, and in many cases were promptly uprooted. The haulage ropes also, at first, were much too light, and constantly broke at the critical time. The weight of the dredge is 250 tons, and the pull on the ropes was 60 tons. Progress for some time was very slow, but toward the end of the journey an average advance of 60 ft. per day was maintained. Trouble was experienced throughout the job by the tendency of the skids to shift to one side directly the weight came on them. The ground in some places also caused great delay, owing to its softness and consequent inability to bear a load.

The management claims that if the question of a further removal occurs again, the same method will be adopted, with the exception that many of the initial mistakes will be avoided, by the experience which has been rather dearly bought. An improvement on the method would be to lay a line of rails and mount the dredge on small wheels, when progress would be greatly facilitated and much work save in the moving of the heavy skids from length to length.

The cost of the work was about £800. The best method of moving, if terms had been agreed upon, would have been to work through the Britain ground. This could, at an outside estimate, have been done in a month, and, although a sluicing plant had previously treated the ground, a certain amount of tin would have been obtained from the dredge as it worked through. With regard to dismantling, it must have proved quicker than the present method, but the dredge is old, and some difficulty would have been experienced in putting it together again. It could, however, probably have been dismantled, removed, and rebuilt in three months. It is said that at first a contract was made to shift the dredge for £300 in three weeks, but the contractor had to relinquish the task, which was then taken up by the company's engineer.

Negotiations are proceeding between the Lieutenant-Governor of Papua and the Commonwealth Government for a loan of £80,000, to be spent in developing the gold mining industry of Woodlark island and the copper fields in the Astrolabe district.

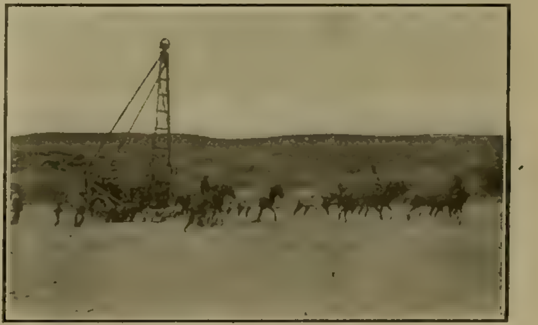
Tube Concentrator in the Coeur d'Alene

By W. A. Scott

The plant of 119 tube concentrators, built as an auxiliary to the Morning mill of the Federal Mining & Smelting Co., at Mullan, Idaho, has been in operation since May 15, 1911, and the results have been so satisfactory that the company is negotiating for the building of another unit of equal capacity to that now in operation. The original plant, as designed by O. B. Hoffstrand of the American Direct Concentrator Co., had an estimated capacity of 50 tons per day, but this has been exceeded. During the month of October the average was 61 tons per day, the month's output having been 200 tons of concentrate carrying 48 to 49% zinc. According to tests made in operating the mill it has been demonstrated that by keeping the flow surface in the tubes crowded, or fully covered, the grade of concentrate produced is higher than that obtained while running with lighter feed. The original practice was for some of the tubes to re-treat the middling of the other tubes, and this no doubt will be eventually the accepted practice after the present equipment has been doubled; but during the past three months all tubes have been given direct feed, with no re-treating of the middling, and this has resulted in raising the capacity of the present plant to 95 tons per day, giving a concentrate product of close to 300 tons per month that is estimated to sample 49% zinc. The object of this temporary practice is to recover as large a tonnage of zinc as possible at a sacrifice of the higher saving effected by the aid of reconcentration. The material treated consists of the middling and tailing from Wilfley tables and the tailing from vanners, containing zincblende, siderite, and silica, also a small percentage of galena that is mechanically associated with the blende. This flotation process effects a separation of the zinc sulphide from the siderite, the former floating on the surface of the water, the latter sinking and passing out with the gangue. The use of sulphuric acid in the process is found to be an aid, as it serves to cleanse the surfaces of the sulphide particles, making them more amenable to flotation; but the quantity of acid used does not exceed 2c. per ton treated. The operation of the plant, especially while some of the tubes were used in reconcentrating the middling of the others, has given results equivalent to those indicated by the original tests made by the General Engineering Co. before the mill was built. Mr. Hoffstrand, who designed the plant, has had general charge of its operations for the Federal company.

Travel Under Difficulties

The sandy deserts of the intermountain region present much difficulty to traction machinery, both because of the sinking of the driving wheels into the loose soil and the rapid wear of the driving machinery from the fine sand which arises. As is usual on the desert, resort is had to primitive means, and the accompanying illustration shows a traction drill being drawn by a string of horses across a sandy desert in southern Utah.



The Caylloma Silver Mines

By Fernando C. Fuchs

The Caylloma silver mines in southern Peru, discovered and worked on a large scale by the Spaniards, are in the Department of Arequipa, about 170 kilometres by trail from the Southern railway. Records in the possession of the British Institution of Mining and Metallurgy show that the production of these mines from 1668 to 1675 was 2,412,359 oz. of silver, while the Caylloma Silver Mining Co. produced, from 1890 to 1905, by amalgamation, operating a dry 30-stamp mill at San Ignacio, 1,779,135 oz. of bar silver and exported 3,753,143 oz. in the form of ore.

From 1906 the Sociedad Explotadora de Caylloma (British) introduced wet crushing, operating 30 stamps with classifiers, Buss concentrating and Luhrig slime tables, and ball-mills, utilizing water-power. The ores formerly ran 2.5 kg. per ton, though at the present time they are from 0.6 to 0.8 kg. per ton, the concentration being at the rate of 11 into 1, with a saving of 60%. Tests have been made for cyanidation, which it proposed to introduce. The ores are brought to the mill by tramway, and the concentrate shipped by mules and llamas to the railway.—*Peru Today.*

Danger From Steel Stacks

A steel smoke-stack danger, where the stack passes through a wood roof, is revealed by the statistics of fires in electric light and power stations in the *Quarterly* of the National Fire Protection Association. Out of eighteen fires in boiler plants, six of them were due to the steel-stacks being placed too near woodwork. As such a cause has probably been the source of fires in many boiler plants the details of construction at this point in the roof deserve consideration. It is self-evident that if a hot stack is close to woodwork, the latter is likely to become ignited. Even where some distance separates the stack from the woodwork, and the intervening space is covered by steel plates, enough heat may still be transmitted by the latter under exceptional circumstances to render such construction a source of danger. Another cause of trouble at this point has recently been suggested by the John C. Paige Insurance Agency of Boston, which has been investigating the subject. The difference in temperature between the portion of the stack above a roof and below it may be great enough, it is suggested, to cause some condensation of the acid products of combustion near the roof line, and these may cause a rapid corrosion of the stacks from the inside, so that eventually small holes will be eaten through it and afford an outlet for those minute sparks which are believed to cause some of the fires originating on boiler-house roofs. Whether or not this is a tenable theory, the fact remains, that there are good reasons for allowing a free air space entirely around one of these stacks and protecting it by a steel plate umbrella attached to the stack some distance above the roof opening and spreading out around the latter so as to protect it without touching the roof. The opening itself should have a cylindrical ring of sheet steel projecting above and below the roof.—*Engineering Record.*

Good iron deposits are known to exist in various parts of Siberia; the principal one in the Amur province is situated in the Little Hingan mountains, on the bank of the Samara river, and is estimated to contain about 350,000 tons of ore, averaging 50 to 70% iron. The principal known iron deposits in the Maritime province are near Nikolaievsk and St. Olga, on Olga bay. The former is estimated to contain 2,250,000 tons, averaging about 43%, and the latter about 1,850,000 tons of magnetite, averaging 56 to 61% iron. None of these deposits, however, is being worked, due principally to the lack of capital and the drawbacks to general mining conditions. An important zinc mine situated on the Tutiha river near St. Olga bay is at present being operated, the output in 1909 being about 9500 tons of ore.

A Source of Error in Metallurgical Tests

By George A. James

In grinding samples containing free gold in modern laboratory grinding apparatus, no matter what degree of fineness is obtained, or the amount of free gold contained, it is unusual to find metallic particles on the sieve. Native gold is almost always brittle enough to be reduced to the fineness of the gangue. This, of course, is the ideal condition for accurate assaying, but when this pulp is to be used for metallurgical experiments, it introduces a fatal source of error, and will give higher amalgamation or cyanide extraction than can be obtained from pulp produced by the tube-mills, or roller mills used in metallurgical plants, which have in a comparatively small degree this grinding and scouring action. Where samples are not ground finer than 40 mesh, by making a gradual reduction in size and sifting frequently, it will be found that this error is comparatively unimportant, but where samples are slimed for agitation test, with cyanide, the results are to be considered as unreliable, and should be checked up by samples prepared in tube-mills.

A Bangkok Custom

The Appeal Court has given judgment in an interesting test case dealing with the custom of Bangkok merchants in receipting the bills sent out with the collector. Originally, in the bankruptcy of Kee, Chiang & Co., Behn, Meyer & Co., Ltd., put in a promissory note on which over 880 taels were still due. The note bore a receipt on its face, and the Official Receiver refused to accept it on the ground that, according to the receipt on the face, it had been paid in full. Behn, Meyer & Co. appealed to the International Court against this decision, but the International Court upheld the Official Receiver's view. The case was then taken to the Appeal Court, Behn, Meyer & Co. asking for leave to call evidence of custom. This was granted, and E. C. East, A. N. Warrack, and E. Leth gave evidence as to Bangkok custom. The Appeal Court then gave judgment reversing the decision of the International Court, stating that in view of the fact that the promissory note remained in the hands of the payees, the fact that the note bore a receipt on its face made no difference.—*Bangkok Times.*

Queensland Gold Yield for October

The output of gold in Queensland for the month of October was 30,547 oz. fine, of the value of £129,755, a decrease, when compared with the corresponding month of last year, of 6014 oz. in weight and £25,546 in value. Charters Towers shows an increase of 939 oz., and the Rockhampton fields also recorded a small improvement. On the other hand, there were decreases at Cloncurry of 307 oz.; at Gympie, of 507 oz.; at Mount Morgan, of £4009; and at Ravenswood, of 87 oz.; while from the Etheridge field the falling off was 692 oz. The returns do not include the output of the Croydon field for October, as that was not available when they were made up. The dividends declared by gold mining companies for October totalled £12,387. The gold yield of the State for the expired ten months of the present year was 314,721 oz., of the value of £1,336,848, a decrease, compared with the corresponding period of last year, amounting to 47,929 oz. in quantity and £203,930 in value.

Since wages boards were introduced in Victoria in 1896 they have (according to an estimate prepared for the Department of Labor) increased the pay of workers coming under their jurisdiction by £4,477,489. This estimate has been arrived at by comparing the rates of pay in operation prior to the awards of the various wage boards with the average wage in force on December 31, 1910.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling and smelting

BAUXITE is infusible, even before the blowpipe, and in the manufacture of aluminum it is dissolved in a fused bath of cryolite. Ore containing so little as 27% Al is low grade, and probably would be unsalable under ordinary conditions.

THE fundamental requirement for the successful working of an ore deposit is that there should be a sufficient amount of ore recoverable to pay for the direct and indirect cost of its removal, and yet still leave a margin for profit. The cost of mining the ore is governed by a number of principles, which vary greatly according to the local conditions.

SOLID walls of either stone or concrete collect moisture on the inside, and not only keep the interior damp, but the floor and walls will become soiled and discolored. Weatherboarded plank on a steel framing has a low first cost, but has a high insurance rate. The best wall is reinforced concrete, using a thin curtain wall, and facing around windows and doors with buff brick secured by metal anchors.

PENNSYLVANIA was the first producer of coal, in 1814, and has been by far the largest producer in the United States, according to the United States Geological Survey, having now a record which surpasses all foreign countries except England and Germany. Pennsylvania's total production since the beginning of mining has been 4,432,071,767 short tons, or more than one-half of the total production of the United States.

A LOOSE PULLEY may be balanced in the following way: After it has been bored out ready for use, place it upon a smooth arbor that is solidly supported in place. Wind a cord around the hub, or the rim, according to the size of the pulley, and give the cord a long even pull, that unwinds it, setting the pulley in motion like a horizontal top. The inner end of the cord is not tied to the pulley, but left free, except that the cord crosses to hold it in place. When the pulley is perfectly balanced it will run a long time without 'chattering.'

TO MAKE rubber packing air and steam-tight, brush it over with a solution of powdered resin in ten times its weight of strong water of ammonia. This mixture when first made is unfit for use, but in three or four weeks it readily adheres to rubber as well as to wood or metal and becomes absolutely impervious to liquids. A good cement for joints in steam or water pipes, and which will set under water, is composed of 4 lb. paris white, ground; 10 lb. litharge, ground; ½ lb. yellow ochre, fine; ½ oz. hemp, cut short. Mix well with linseed oil to a stiff putty.

BY USING a steel framework for a building, much of the uncertainty as to its safety may be done away with. There is also a saving of head room and floor space, as the steel beams and columns are smaller than those of reinforced concrete. In a building of many stories a few inches to each story adds up to quite an item. The columns in the lower stories become so large that, as one writer has put it, the building resembles the Egyptian pyramids—most of the room is on the outside. Nor are engineers agreed as to how concrete sets when poured wet in large masses.

EUROPEAN countries have found workmen's compensation acts of little use, unless obligatory insurance guarantees the compensation awards to the injured workmen without overburdening the small employer. There are, therefore, found many forms of insurance plans in the different countries. Without going too deeply into the various plans, they can be divided into two classes, compulsory and voluntary, which, again, can be divided into sub-classes, (a) compulsory insurance in prescribed institutions, (b) compulsory insurance with choice of insurance institutions. Under the voluntary insurance there are: (c) private companies or mutual associations, with State institutions competing; (d) private companies or associations, without State institutions competing. In a general way, the following countries come under these four heads: (1) Compulsory insurance: (a) Norway, Luxemburg, Hungary, Austria, Germany, and New South Wales; (b) Italy, Netherlands, and Finland. (2) Voluntary insurance: (c) Sweden and France; (d) Belgium, Denmark, Great Britain and her colonies, Russia, and Spain.

DRY BATTERIES which have become exhausted can be re-charged by a very simple process. Remove the outer cardboard casing from each cell and drill six small holes in the zinc casing about 1 inch from the bottom. As four cells are generally used for ignition purposes in connection with an induction coil, get four small glass or stone jars an inch or so larger in diameter than the cells and about three-quarters their height. Dissolve about ½ oz. of powdered sal-ammoniac in each jar, in a sufficient quantity of water to bring it almost to the top of the jar when the cell is in it. Get four cells of gravity battery and put them in series with each other by connecting the zinc element of one cell to the copper element of another. Put each dry battery cell in the solution in its respective jar and connect the three binding posts of the zines together, and the three carbon posts also, by means of insulated copper wire. Then connect the zines to the zine and the carbons to the gravity element of the gravity batteries. Allow the cells to remain over night, and if they are of good reliable make they will be found in the morning to be almost as good as new. The process of recharging dry batteries can be repeated at least twice, and even three times, but, of course, after each successive re-charging their renewed life will be shorter than before. After the batteries have been re-charged the small holes, which were drilled in the casing, can be stopped by means of a strip of adhesive tape, covered with bicycle tire cement, and tightly wrapped around the zinc casing over the holes. The cells should be thoroughly dry and then may be replaced in their cardboard casing ready for use.

TO TEST for vanadium, the mineral may be digested with nitric acid. If hydrogen peroxide be added to the resulting liquid, a brown color will appear if vanadium is present. Some vanadium minerals are also attacked by hydrochloric acid and by sulphuric acid. To the solution resulting from the use of either acid, hydrogen peroxide may be added, and a brown solution will show the presence of vanadium, as when nitric acid is used. If either hydrochloric or sulphuric acid is used, metallic zinc may be added after hydrogen peroxide, and a bright blue color will be given by the reduction of vanadium compounds. The same effect can be obtained in a nitric-acid solution by adding sulphuric acid, evaporating to white fumes, diluting, and adding metallic zinc. If preferred, hydrochloric acid instead of sulphuric acid may be added to the nitric-acid solution, but in that case evaporation must be carried almost to dryness at least twice to get rid of the nitric acid. The liquid may then be diluted and more acid added, followed by zinc as described. At times the tests given above are not wholly satisfactory. In such cases, if the apparatus is at hand, pass hydrogen sulphide (H_2S) gas through a filtered solution made alkaline with ammonia until it is saturated. The solution will take a fine garnet or deep wine color if vanadium is present. Copper, if present, is precipitated as a sulphide and does not interfere with the test. If commercial iron sulphide for making hydrogen sulphide gas is not at hand, pyrrhotite, galena, or zincblende may be used with hydrochloric acid. The only accessories needed are two test tubes, one of which is closed with a cork in which is inserted a bent tube, the other end of which can be placed in the solution to be tested for vanadium.

Special Correspondence

JOHANNESBURG, TRANSVAAL

RANDFONTEIN MINES HEAD GOLD PRODUCERS FOR OCTOBER. —REPORT ANALYZED.—GELDENHUIS REPORT.

For the first time in its long history, the Randfontein mines headed the list of gold producers on the Rand in October with a declared output of 60,778 oz., valued at £258,169. This is an achievement upon which all who have taken a hand in the development of this property are to be congratulated, because it represents many years of labor, and, like other big concerns on the Rand, the Randfontein property lately has been subjected to much misrepresentation and abuse. It has certainly taken many years to bring the Randfontein property to its present stage of production, but, with its equipment totaling 1000 stamps and the accompanying tube-mills and cyanide-plant, it is now in a position to give a good account of itself. With an adequate supply of native labor it should be able for some time to come to put up a good fight for the position of largest producer on the Rand and likewise premier gold producer of the world. However, huge properties like the Randfontein, as has recently been shown by the East Rand Proprietary Mines affair, are subject to disappointments, as the larger the area the more liable to variations of grade, and no real importance need be attached to any fall of grade which is reported to have occurred in the northern section of the property. Seeing that the Randfontein property is a huge faulted outlier of the upper Witwatersrand and beds, no one can say with certainty what is likely to occur in depth, especially at the extreme southern end of the property. The fact that the shaft of the Randfontein Deep shows signs of approaching the reef, ought, if widths and value of the ore are maintained, be sufficient to place the permanency of the largest and most important portion of the Randfontein property beyond doubt, if any ever existed in the minds of those interested.

The Chamber of Mines' declaration of the October output as 708,644 oz., of a value of £3,010,130, perhaps did not come up to expectation, on the whole, yet the whole output of the East Rand Proprietary Mines was not declared, and nothing from Glynn's Extension in the Lydenburg district appeared, while no one was prepared for such a shortcoming as that displayed at Geldenhuis, notwithstanding that the gold held in reserve by this property was reduced from 1646 to 1020 oz. The total gold output of the Transvaal has been well established as above £3,000,000 per month, and with a slight improvement in the labor position the Rand itself could easily produce this amount. Perhaps as it is, the Rand will soon claim the honor of a gold output valued at £3,000,000, despite its labor troubles and the inability of the Victoria Falls Power Co. to meet the power requirements of the mines. The returns also show that the marked increase in the number of stamps dropped in September was due to the desire to avoid coming under the Sunday law, whereby it is proposed that all stamps coming into operation after September 30 shall not be allowed to work on Sundays. Even in the days of the old Transvaal Republic, when religious prejudice prevailed among the Boers to a greater extent than today, Sunday milling was allowed because it was considered a necessity, so that some surprise was expressed when such strong opposition was shown in the Union Parliament against Sunday milling which even the persuasive manner of the Minister of Mines could not remove. Only 9450 stamps on the Rand, 589 outside, making a grand total of 10,039, were operated during October, as against 9675 and 632, respectively, a total of 10,307, in September. There thus was an apparent reduction of 299 stamps in October, while in tube-mills there was a net decrease of only one for the month. The average daily yield for October was valued at £92,891, and it is necessary to go back six months to find a lower average daily output. The labor position, as far as the gold mines are concerned, is distinctly worse than during the other periods of the present year. Figures show that it continued to improve until April last, when the total number was 194,328, but in October it had fallen to 179,194, against 183,268 in January. The following table shows the companies producing over 20,000 oz. in October:

	Tons milled.	Yield, oz.	Value.
Randfontein	212,510	60,778	£258,169
Crown Mines	148,900	60,275	256,032
East Rand Proprietary	169,256	51,028	216,753
Robinson	51,700	27,278	115,870
Simmer & Jack	73,200	22,067	93,735
Geldenhuis	67,220	21,365	90,753
Rose Deep	61,000	20,668	87,792
Robinson Deep	53,200	20,213	85,859

The Gendenhuis property declared an estimated profit of £15,050 for October as compared with £18,900 in September, the official explanation being that the grade of ore mined has been below normal. It is added that steps have been taken to mine more in accordance with the average grade of available ore reserves. No explanation is given as to why, during the month of October, mining operations were not conducted so as to reflect the true value of the available ore reserves in the returns, and for well known reasons such an explanation no doubt would be interesting. The Geldenhuis property has just been placed under the control of an engineer who recommends concentration of underground operations so as to bring about a reduction in the average working cost per ton, and the adoption of this new system of working may, or may not, be the cause of the marked fall in grade and profits. This same engineer has recommended the adoption of a similar plan of concentrating the underground workings at the neighboring Nourse Mines, with the object of reducing the working cost per ton, and providing that, if after the experience at the Geldenhuis, this system of concentrating underground operations at the Nourse Mines is carried out, much interest will centre in the results, especially as regards the resulting grade and profits. It has hitherto been the general custom on the Rand to scatter the mining operations so as to make the grade fairly representative of the average of profitable ore reserves, which has naturally resulted in the average working cost per ton being higher than if concentrated mining were adopted. The advantages of this system are evident, as on the Rand grades vary quite perceptibly over limited areas, even if they always keep above the profitable or economic limit. The excellent and easy underground mining conditions on the Rand also lend themselves readily to this system of mining, in addition to the advantage of producing an ore approximating uniform grade on the whole. There can be no doubt that concentration of mining operations must result in lower average working costs on the Rand, but it will also produce varying monthly results and will call for a much higher and more varying gold reserve to be kept on hand. Whether this concentrated method of mining is one to be adopted must depend, of course, upon the prevailing circumstances of the

RANDFONTEIN CENTRAL MILL.

mine. The time, however, has not arrived when concentrated mining has become essential on the Rand. When the mines reach such a depth as to make it necessary, not only will concentrated, but wholesale mining, with its attendant advantages and disadvantages, be required.

LONDON

British Aggressiveness in Arizona Copper Co. Policy.—Encouraging Report of Great Cobar, Ltd.

A great scheme for the expansion of operations has been adopted by the shareholders of the Arizona Copper Co., a British corporation with headquarters in Edinburgh, and owning the Longfellow and Metcalf groups of mines near Clifton, Arizona. Operations started in 1882, but like many other copper ventures in that part of the world, the early days were anxious ones. During recent years the venture has been highly profitable, and, for the last completed year for which the accounts have been published, the profit was £250,000, sufficient to pay 50% dividend on the ordinary shares; the output of copper was 14,739 long tons, and the yield 2.15%; moreover there is no gold or silver content. It has been known for some years that there are enormous ore reserves averaging less than 2%, but their profitableness was a debatable point. Seeing, however, that other mines in that part of the world had demonstrated the possibility of beneficiating this class of ore at a profit, the Edinburgh people decided to take steps to investigate the chances in this direction for their mines. At first, with characteristic Scottish caution, they were inclined to spread the necessary expansion of the mine operations, the concentrator, and the smelter, over a series of years, without issuing any new capital, and their former manager, James Colquhoun, favored this plan for extension. But L. D. Ricketts, who was called in to advise, strongly urged the bolder course of making a clean sweep and providing immediately the best and most up-to-date plant possible. He showed that with a plant of similar type to that at Cananea a saving in expenses of a million dollars per year could be effected by the expenditure of $2,500,000, and that there was enough proved ore to yield 20,000 tons of metal for ten years, besides immense resources in the way of probable and possible ore, averaging not much less than 2%. Accordingly the directors and shareholders have accepted Mr. Ricketts' proposition, and the capital is to be raised by the issue of £500,000 debentures. A large part of these debentures are already subscribed and I feel sure that the rest will be forthcoming.

Mr. Ricketts' scheme involves the building of oil-burning reverberatory furnaces, the gases from which will be used for steam-raising and the generation of electric power. It is estimated that 2200 hp. can be obtained in this way, and that this will save £66,000 per annum in the fuel bill. The power will be sufficient for the metallurgical works and for the greater part of the requirements of drilling, hoisting, and hauling at the mines. The concentration plant is to be remodeled by the scrapping of No. 3 and No. 4 mills at Clifton and the enlargement of No. 6 at Morenci. The whole of the concentration, therefore, will be done at one spot. The capacity of the enlarged mill will be one million tons per year. Many improvements are required in the mines, and in the methods of hauling, so as to fit the new requirements. As regards the new smelter, it is fortunately possible to acquire a site not far from Clifton, large and level enough to provide the necessary room for efficient mixing and preparation of the ores. Altogether the scheme is one of prime importance, and its adoption is a good example of the untruthfulness of the jibe about British lack of enterprise.

The Great Cobar mine in New South Wales has had a checkered career since it was owned by an English company. On its flotation here in 1906, an enormous sum in cash (some £800,000) was paid to the local owners, who had made fortunes out of the ores in the zone of secondary enrichment. They evidently sold at the right time as far as they are concerned, for though the ore deposit has been proved to be persistent and of great extent, the content is nowadays only 2½% copper, contained in pyrite. The smelting problem has therefore been difficult, and the expense of flux, and the low content of the smelting charge has made for high costs. The designer of the new smelting plant made many mistakes, and the expenditure in getting matters put straight again has been great. H. C. Bellinger, formerly of Montana, has straightened out the metallurgy and improved the system of development. The most important step taken recently has been the purchase of the Cobar gold mine which yields a silicious ore containing 10 dwt. of gold. The Cobar gold mine was not a success financially while working on its own account, as the antimonial content had a deleterious effect. So the consolidation of the two interests was to the advantage of both parties. The Chesney copper mine has also been acquired. The company now appears to have passed its troubles and to be on a sounder commercial basis. The English public has been much perturbed during the past half year or so because the directors have not issued a report nor convened a meeting of shareholders. All sorts of rumors have been flying around in consequence. In order to be perfectly fair, it is best to give an abstract of the belated report now issued, covering the eighteen months ended June 30 last. During this time two stoppages of a month each were made, one due to the coal strike and the other to repairs in the main shaft. The operations have been hampered by labor troubles, and the costs have increased owing to the rise in the rate of wages. Capital has been spent in developing the Great Cobar, the Chesney copper mine, and the Cobar gold mine, and in building a concentrator at the Chesney, which will be in operation early next year. The company then should be able to maintain a regular output from all the mines and to produce a suitable smelting mixture. The Cobar gold mine promises to be an exceedingly useful factor in the situation, providing a silicious mixture for the pyritic ores of the other mines. The monthly outputs will be 26,000 tons from the Great Cobar, 13,000 from the Chesney (to be concentrated to 5000 tons) and 9000 from the Cobar gold mine. During the 18 months under review, 386,154 tons of ore was raised from the Great Cobar, 46,137 tons from the Chesney, and 43,697 tons from the Cobar gold, a total of 475,988 tons. The smelter treated this ore and also some of the accumulated stock and purchased material, the total amount being 606,791 tons. The production of the smelter was 9652 tons copper, 36,649 oz. gold, and 174,657 oz. silver. During the last 6 months of the 18, the assay of various ores were: Great Cobar, 0.98 dwt. gold, 0.429 oz. silver, and 2.508% copper; Chesney, 1.64 dwt. gold, 0.369 oz. silver, and 3.287%; Cobar gold, 0.5 oz. gold, 0.5 oz. silver, and 1.32% copper. On June 30 the reserves were: Great Cobar, 2,142,000 tons; Chesney, 602,000 tons; and Cobar gold, 344,000 tons. The total reserve at the first two has increased by 361,000 tons during the 18 months. The income during the period was £817,434, and the gross profit £102,354. Out of this £13,000 has been allowed for depreciation, £22,,886 has been devoted to the purchase of debentures, and £66,492 has been paid as interest on debentures. In October 1910, 50,000 new shares of £5 each were created; of these 15,000 were issued at par for cash, and 20,000 were issued as purchase price for the Cobar gold mine, so the issued capital now consists of £925,000 in shares, and there is £732,152 in debentures and debenture interest outstanding.

SILVERTON, COLORADO

Railroads Resume Service.—Iowa Tiger Leased.—Gold King Milling.—Sunnyside Acquires New Property.—Ledge Company Milling.—Congress Developing.

Railroad connection with the South was restored on December 7, and supplies of all kinds are being rushed to this district. An ample supply of foodstuff and coal will soon be on hand and all danger of any shortage is now removed. The weather for the past three weeks has been exceptionally fine for this season of the year and some properties will be able to resume operations this fall. The Iowa Tiger has been leased to Messrs. Otto Mears and Slattery, and the new lessees have a small force at work on the

Tiger mine. Development will be vigorously pushed during the winter, and the lessees hope to resume milling at full capacity in the spring. The railroad to Gladstone was promptly repaired and the lessees of the Gold King are milling. The tonnage will be increased as rapidly as possible and the mill may soon be at full capacity. Forty men are employed at present. The Sunnyside has taken a lease and bond on the property of the Quartz Mining & Milling Co. and will start development on a large scale at once. The Sunnyside continues its steady production. The Ledge is again milling at full capacity and has materially reduced the cost of mining by the installation of a double-drum electric hoist, which does the work of two steam hoists formerly used at this mine. The Congress mine is being unwatered and development will start within the week. The Gold Bug at Bear Creek has laid in supplies for the winter and will resume shipments in the spring. The Intersection has been leased for a period of five years and the milling capacity will be doubled by the addition of another battery of five stamps. The re-establishment of railroad communication and the continued good weather are sources of great encouragement to the operators of this district, but many plans will be delayed at least six months. The season of 1912 is looked forward to as one of vigorous development, and there is every reason to believe that 1913 will find this in the front rank of Colorado mining districts.

MINES AT BISBEE.

NEW YORK

Development in Miami District Merger.—Greene-Cananea May Pay 50 Cent Dividend.—New Producers Threaten Increased Copper Output. — Porphyry Notes.

The merger of the principal properties in the Miami district is 'marking time.' L. D. Ricketts, general manager of the Greene-Cananea, has just returned from Glasgow, where he went to report upon the properties of the Arizona Copper Co. Mr. Ricketts will represent the Cole-Ryan interests in the negotiations that will take place between the Live Oak, the Inspiration, and the Miami companies. The Cole-Ryan people, which Mr. Ricketts represents, have something more than a passing interest in Arizona Copper and are undoubtedly anxious to see this old producer properly equipped and turning out copper as it should, and no doubt will, do. The Raritan refinery, now a part of the International S. & R. Co., has for many years handled the copper of the Arizona Copper Co., while the metal has been sold by the United Metals Selling Co. It will be recalled that about a year ago the Cole-Ryan crowd made a strong effort to secure control of the Arizona Copper Co.; failing this, it is but natural and proper that they should be anxious to have Mr. Ricketts reconstruct the plant and repeat for the Scotchmen the splendid work that he did with the plant on the Greene Consolidated. Mr. Ricketts' work with the tumble-down plant that Mr. Greene left is bearing its first fruits. It is anticipated that the Greene-Cananea subsidiaries can make a distribution of profits the first of the year that will allow the Greene-Cananea to pay a dividend of 50c. Greene-Cananea is one of the properties that will stand ready to extend itself under the stimulus of higher prices in the metal market; with 14c. copper Greene-Cananea should make some records for itself, for the new plant, and for Mr. Ricketts, who built and rebuilt it. On the Live Oak, the last property to come under Mr. Ricketts' charge, and which was acquired while he was abroad, the churn-drills are at work and the data are being gathered for an accurate estimate of the ore, developed and partly developed. The reduction plant of the Miami is nearly all installed, the fifth unit of the concentrator is just being started up, and the sixth and last unit will be started in January, when production is expected to reach 3,000,000 lb. of copper monthly. It is anticipated that the Miami plant will be enlarged to care for the ores of all three properties if the contemplated merger is finally effected. It is stated from confidential sources, upon what appears to be good authority, that, while negotiations have not been discontinued, there is no real hope of the consolidation being made.

While it is the fashion of the moment to point with pride to the restricted output of the past month or two as being partly responsible for the betterment of the copper metal market, and to lay no emphasis on the prospects of the new producers, there are, nevertheless, several properties about to begin turning out copper. The Mason Valley smelter at Yerington, Nevada, has been completed and is just about to be blown in. The Mason Valley mine will turn out about 1,000,000 lb. of copper per month, and the smelter will have custom business from the Nevada-Douglas, which is to furnish 10,000 tons of ore per month, and will eventually handle ores from the Bluestone and several other as yet undeveloped properties in the immediate vicinity. The Mason Valley is owned by the Inspiration people. Another producer that is making preparations to 'come back' is the Shattuck-Arizona, which is about to build a small smelting plant, costing some $450,000, which will have two blast-furnaces, each of 400 tons capacity. The Shattuck-Arizona is one of the most promising of the newer mines at Bisbee, Arizona, and has the distinction of making some copper for a little less than nothing, if that be possible. In its first days of operation, it produced about 1,000,000 lb. of copper one month, when the precious metal content of the ore a little more than paid all expenses. Tuolumne, a neighbor of North Butte, has suspended dividends and has installed a large Nordberg hoist, in the meantime developing the ground and taking out only about 100 tons of ore per day. It is making preparations for greatly increased production, which will surely follow close upon the heels of the present advances in price of the metal. Pilot Butte, which is in turn a neighbor of the Tuolumne, has made a rich find in zinc. A part of the Pilot Butte ground lies near the Elm Orlu, W. A. Clark's mine, which is a heavy zinc producer, and it is thought the new find is important, as indicating a big zinc output for the Pilot Butte. With both Granby and British Columbia ready to begin operations on an enlarged scale, after a forced shut-down, to say nothing of the much-talked-of output of the porphyries, there will hardly be any runaway market for the metal. As 14-cent copper will prove a great stimulus to production, it may be confidently expected that during the next six months production figures will show that all curtailment hobbles have been thrown off, and every one will ride to beat the other fellows to the market.

Phelps, Dodge & Co. is forming a subsidiary mercantile company to take over all of the business of the company stores controlled by the various Phelps Dodge mining companies. The Phelps Dodge Mercantile Co. has been incorporated under the laws of the State of New York, with a capital of $400,000. The Phelps Dodge company has just declared its usual quarterly dividend of 2½%, and 2% extra, making the disbursement for the year total 12%, which is the same as was paid in 1909 and in 1910.

Henry Krumb has just completed his report upon the Inspiration, giving an estimate of ore reserves up to December 1. He figures developed ore reserves at 30,302,300 tons, with an average copper content of 1.95 per cent.

The Calumet & Hecla management is bending all its efforts toward a reduction of copper costs at various properties which it controls. One large cost item is being cut down by the use of one-man drills, and an order for 1000 drills was recently placed. Several of the lake mines, which have been unable to take out a profit for some time, are now, under closer management and with improved prices, expected to run ahead of the expense account by a fair margin.

It is somewhat monotonous to chronicle another reorganization of the Nevada Utah. It has been some years since anybody could follow the mazes of the various windings in and out of the corporate formation of the Nevada Utah, and another convolution more or less is mainly interesting only to shareholders, who will probably be called upon for an assessment in some form or other.

Never, since the days prior to the first discoveries at Tonopah and Goldfield, has interest in precious metal mining been at so low an ebb in the East. The flattening out of the excitement at Porcupine, and the continued unrest in Mexico, which lately seems to have become more serious, are two elements that are most important. Mexican mining properties are largely held in New York, but to enlist any new capital is out of the question under prevailing conditions, while trading in the shares and trading in properties are alike at a standstill.

A recent feature of the rooms of the American Society of Mechanical Engineers, in the Engineering building, New York, has been the exhibition of a portrait of the retiring presdent of the society, E. D. Meier. The portrait was painted by D. J. Strain and is the gift of members to the Society to commemorate Mr. Meier's seventieth birthday.

GLOBE, ARIZONA

CHURN-DRILL HOLE NO. 1 OF SOUTHWESTERN MIAMI DISCONTINUED.—DEVELOPMENT AND PRODUCTION NOTES.

Churn-drill hole No. 1, of the Southwestern Miami Development Co., has been discontinued at a depth of 1285 ft. without passing through the orebody, the bottom of the hole being in ore. On account of the great depth and the fact that the ground was caving badly near the bottom of the hole, it had to be abandoned. It is by far the deepest hole ever drilled in the Miami district. The drill will be moved to a location 400 ft. east of this hole and about 450 ft. from the nearest holes on Live Oak ground, some of which are known to have disclosed good ore. Hole No. 1 seems to have proved beyond doubt the continuation of the Live Oak orebody into Southwestern Miami ground, having disclosed a thickness of 175 ft. of chalcocite ore. Assay returns are not made public, as it is the policy of the management to withhold this information until more holes have been drilled, so that an estimate of tonnage can be made. Two churn-drills remain in operation on the ground of the Live Oak Development Co., one of the holes being now in ore. It is reported that the engineers' estimates differ as to the tonnage of ore developed, the Live Oak company claiming 19,000,000 averaging 2.11% copper, of which 15,000,000 will average 2.25%, while another estimate placed the figure at a total of 14,000,000 tons. It must be remembered, however, that the lower estimate was made by a prospective buyer. There as yet seems to be no reason to doubt that the official estimate of the Live Oak management was based on careful sampling, assaying, and computation, although there may be a difference of opinion as to what constitutes developed ore.

At the Superior & Boston, the cutting of the station on the twelfth level in the McGaw shaft is nearly completed and the cross-cut to the Great Eastern and Old Dominion veins will soon be continued. It is quite probable that diamond drilling will not be resumed, as the results obtained were not as satisfactory as the initial drilling led the management to expect. It was thought that the homogeneous diabase formation could be easily penetrated by the diamond drill, and slow progress was made for the first few days. Then numerous slips and small faults began to be encountered, forming alternate stretches of hard and soft material so that progress became very slow, and it was almost impossible to obtain a solid core. It will probably be three or four weeks before the cross-cut can reach the vein, and the disclosures then made will be of great importance to the Superior & Boston company. At the annual meeting of the stockholders, held at Globe on December 4, the following board of directors was elected: John H. Rice, William G. Rice, Norman W. Haire, John R. Pimlott, and James W. Harrington, the only change in the board being the election of James W. Harrington to succeed George R. Hill. The articles of incorporation were so amended that the board of directors may, at its discretion, increase its membership from five to nine.

W. H. Aldridge, managing director for the Inspiration Copper Co. has spent a couple of days at the mine, and returned to the East on December 6. Regarding the reported negotiations for consolidation of Miami, Inspiration, and Live Oak, he said: "I do not know whether the controlling interests in the properties will succeed in bringing about a consolidation. If a consolidation were effected it would be of great benefit to those interested in the district, as it would involve operations on a very much larger scale than at present, while, from the standpoint of the very many stockholders in the several companies, it would result in a large gain, because of the much lower cost of producing copper and correspondingly large increase of profits. The companies mentioned have developed over 65,000,000 tons of ore of a copper content averaging 2.17%, which would place the consolidated properties among the largest of the big porphyries. The beginning of these negotiations for consolidation will not change the policy of the Inspiration company regarding the present work in the experimental mill, the development of the mine and mill plans, or the providing of a water supply from Pinal creek."

The November output of the Old Dominion was 2,060,000 lb. of fine copper. Work is progressing satisfactorily, and 'A' shaft, which is the main working shaft, is being sunk to the eighteenth level. The work of clearing the Kingdon shaft, recently burned out, is under way, and the management has called for bids for a concrete lining for this shaft, instead of timbering. If bids are satisfactory as to cost, this shaft will be concreted for 1000 feet.

The fifth unit of the Miami concentrator started on December 1, and production should soon be at the rate of about 2,500,000 lb. of refined copper per month. Installation of machinery and equipment in the sixth and last unit is being effected, and this unit should be running early in January, bringing the monthly production of refined copper up to about 3,000,000 lb., based on the present rate of production.

H. F. Wendelborn, who is leasing on the Nevada vein on United Globe ground, is shipping 20 tons per month of ore reported to average about 14% copper. The ore is shipped to the Old Dominion smelter.

It is rumored that the Guggenheim interests have acquired control of the Ray Central. The report adds that a 1500-ton mill will be built.

General Mining News

ALASKA

KETCHIKAN

(Special Correspondence.)—The Mount Andrew and It mines, Kasaan bay, have suspended mining operations for the winter. About 700 tons of ore from the It mine is ready for shipment.

The high-grade orebody at the Rush & Brown mine has been discovered on the 200-ft. level. This property is being developed by the owners under the management and supervision of U. S. Rush.

The Princeton M. & M. Co., at Dolomi, has suspended operations until early next spring, when a 20-stamp mill will be erected.

A new orebody was uncovered on the Copper Center group and another large orebody was discovered on the Gopher property, formerly known as the Hydah group. The latter body is being prospected, and shows good ore at present. M. L. Polson is superintending the work, which will only consist of assessment work for the present year.

M. D. Ickis has returned from Dall island, where he had charge of the assessment work for the Ketchikan Marble Company.

The Gervis Bros., at Hollis, are taking out high-grade gold ore and cutting a winter trail to facilitate sledding the ore to tidewater during the winter.

The Lond De Van adit at George inlet is in about 1850 ft. It is expected to cut the vein at about 2500 ft. from the portal.

Ketchikan, December 11.

THE TANANA

Cooper & Stillman, of the Rexall quartz claims on Wolf creek, have sacked 15 tons of ore assaying about $100 per ton, says a report from Fairbanks.

Ground panning as high as $2.50 per square foot has been discovered on Flint creek in the Ruby district.

The vein on the Ryan Lode group, St. Patrick creek, has been traced by drills for 1200 ft. An adit will be driven from the base of the hill where it was discovered.

ARIZONA

GILA COUNTY

(Special Correspondence.)—At the Inspiration, the experimental mill is running steadily under the supervision of J. M. Callow. At the site of the proposed dam at Wheatfields, sixteen miles from the mine, test-pits sunk in the bed of Pinal creek disclosed bedrock about 12 ft. below the surface. Excavation is being made for a large steel warehouse near the mouth of the main adit. The gravel from the gulch near the mouth of the adit is being tested as to its suitability for the making of concrete. Development steadily continues at the Live Oak. Work at No. 2 shaft is at present confined to the cutting of a station at the 900-ft. level. The Miami Copper Co., with five of the six units of the mill in operation, is mining and milling 2500 tons of ore per day. The fifth unit is reported to be giving good results. Mill recovery is reported to be about 75% and production of refined copper is estimated to be at a rate of about 2,500,000 lb. per month.

The churn-drill of the Southwestern Miami Development Co. has been moved from No. 1 hole 400 ft. east to the location for hole No. 2, and drilling will begin at once. An assessment of $1 per share, payable January 15, has been levied on the 35,000 shares of outstanding stock. The New Keystone Copper Co. is operating one churn-drill on hole No. 41. Results are not made public.

At the Superior & Boston mine, on Copper hill, the cross-cut from the McGaw shaft., on the twelfth level, is being driven north toward the Great Eastern and the Old Dominion veins.

At the Five Points mine of the Manitou Copper Co., fifteen miles west of Globe, the 100-ft. Cracker Jim shaft is being unwatered with a small gasoline hoist, and the road to the property is being repaired. A larger hoist is about to be installed, and as soon as the shaft is unwatered it will be sunk 100 ft. deeper and a cross-cut driven to the Maverick vein. The Sleeping Beauty Copper Co. is employing six men on assessment work on its group of 20 claims nine miles west of Globe in the Sleeping Beauty range. The Orphan Copper Co. is doing assessment work on its 10 claims lying southeast of the New Keystone on the edge of the schist belt near a contact of the granite-porphyry and the schist. The Barney Copper Co. has completed assessment work on its group of 26 claims adjoining the Live Oak on the west.

Globe, December 14.

Advices from Boston state that the United Globe Mines earnings for 1911 will not be far from $200,000, an equivalent of 68c. per share on the 295 shares of the Old Dominion company issued. While a 50c. dividend may be declared, there is some doubt, owing to the recent fire in the Kingdon shaft. It is asserted that the Old Dominion has had a fire in the abandoned stopes of the upper workings for over a year. Since the Kingdon blaze, a second fire was discovered in the abandoned stopes.

PIMA COUNTY

Ore assaying 7% copper recently was discovered at the Copper Queen, state reports from Tucson.

PINAL COUNTY

The Ray Con. Copper Co. in November treated about 110,000 tons of ore in its mill, an increase of 15,000 tons over the preceding month. In concentrate there was produced about 2,600,000 lb. of copper, a proportionate increase. Shipment of concentrate to the El Paso smelter of the Guggenheim interests will be stopped January 1 in favor of the A. S. & R. smelter at Ray. The new smelter, however, will not be placed in commission until April 1, and the concentrate will be allowed to accumulate until then. At the Ray mill a saving of 70% of the 1.8% ore was obtained.

CALIFORNIA

AMADOR COUNTY

Recent newspaper reports state that the newly organized Keystone Mines Co. has taken over the McDonald interest in the Keystone mine. Carlton R. Downs of Sutter Creek is president of the company.

The annual report of the Lincoln Con. M. Co. for the year ended December 15 shows a balance on hand of $6540, after disbursements of $10,610. The south drift on the 800-ft. level is now 669 ft. from the main cross-cut, and the north drift has been extended 300 ft. The south drift penetrated ore in the last 200 ft., but not of commercial grade, taken as a whole. The old 1200-ft. level was cleaned out for about 300 ft. An assessment of 10c. per share was levied.

SAN BERNARDINO COUNTY

(Special Correspondence.)—The California Big Chief M. Co., made up of Providence, Rhode Island, people, has taken a bond on the Jumbo mine, situated in Hart district, from W. M. and L. W. Foster and P. McClusky, the original locators. The property is to be reopened and further developed under direction of F. E. Browne, the company's consulting engineer. The Jumbo has produced ore to the value of about $10,000 during the past five years, consisting of free-milling gold quartz. A stamp-mill is to be built if results of development should justify it. Mr. Browne started from Salt Lake City for Hart December 17.

Hart, December 17.

SISKIYOU COUNTY

(Special Correspondence.)—The Taylor Lake quartz mine, 12 miles from Etna, has been bonded by Chico capitalists from Harris Bros. & Co. Arrangements have been made for the placing of a crew at work. The Owl placer claim, on Orleans Bar, has passed into the hands of W. L. Clark and W. B. Grant, of Los Angeles. Repairing of the flume and other work is under way, and the handling of rich gravel will soon start. The Owl is situated on the high channel, and contains proved deposits of good gravel. The Wright family has purchased the Eastlick placer claim and is arranging for active operations. The Trail Creek M. Co. has completed the erection of a small mill. During the winter development work will be pushed, but no attempt will be made at production until spring sets in. A considerable quantity of milling ore is exposed. The holdings lie near Callahan. A recent test of 100 tons of ore from the Adaline Rocks mine was so satisfactory that the management has decided to build a 40-ton cyanide plant in the spring. A small mill was completed some months ago. Stanwood Murphy is superintendent. New owners of the Barendum & Rostetter quartz property, Plowman Valley district, are arranging for an active spring season. At the McKeen a cross-cut is being driven from the new shaft to intersect the vein.

Etna, December 15.

TUOLUMNE COUNTY

(Special Correspondence.)—A hoist and other machinery will be installed at once at the Morning Glory mine, near Confidence. The shaft is 80 ft. deep, the vein 4 ft. wide, and the assays range $40 to $80 per ton. This property has been called the Jim Lyons mine, and was bonded last September to Allen C. Redding for the reported price of $75,000.

One hundred cars of ore from the Rosedale mine, on Table mountain, yielded $704. The adit is 125 ft. long and has almost traversed the old subterranean channel, but is still being driven. It is now reported that the recent visit here of Oscar Galliee, who was at one time superintendent of the Soulsby mine, was for the purpose of rehabilitating their once noted property.

Men are again working at the Imperial group, the property having been bonded to Buick and Hutchinson, who are also the operators of the Clio. The crew at the latter is being increased and a large amount of development work is planned. M. D. Kelly is superintendent. The Jumper mill will soon be started.

Preparations are under way for reopening and operating the Nonpareil mine, which is held by P. George Gow. An interest in the Robinson quartz mine, an adjoining property, has just been purchased outright by Mr. Gow. The mill at the Gross mine, near Tuttletown, was started a few days ago, but is again idle on account of the water shortage. Work in the mine is progressing as usual.

Tuolumne, December 16.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—An 8-ft. streak of ore has been uncovered on the fourth level of the Smuggler mine on Brown mountain that assays 376 oz. silver and 32% lead per ton. Shipments have been started. B. C. Catren is manager. Work is again in progress on the Raymond adit on Griffith mountain. L. Hoery, owner of the Phonolite property, has resumed operations. Stoping has been started on a body of lead-zinc ore that is 18 in. wide. A company is now in process of organization. The Little Emma mine on Democrat mountain is the scene of an important discovery, a 4-in. streak of gray copper, assaying 835 oz. silver per ton, having been uncovered. E. L. Nubton is operating under lease. A body of 150-oz. silver ore 18 in. wide has been found in the Scepter mine. The discovery was made 2100 ft. from the portal of the adit. Ira Clapper is lessee.

Georgetown, December 16.

(Special Correspondence.)—A 6-in. streak of ore has been found in the Little Champion mine that mills 15 oz. gold per ton. George Hyland is owner. Work has been resumed on the Wyoming Valley adit. J. J. Hoban is manager. Work has been resumed on the Clara mine at Alice. A. P. Alberts is manager. A plant of machinery has just been installed at the Lamartine mine. Electric power will be purchased. John Lang is manager. The Metropolitan adit on Donaldson mountain has been driven 3400 ft. A vein is now being penetrated that is heavily mineralized. Driving is in progress on the Metropolitan vein. Thomas Coppard is manager. A body of ore 18 in. wide has been uncovered on the Oneida vein at Freeland that assays $45 per ton in gold, silver, and copper. John Owen is manager. A carload of ore is being shipped daily from the lease being operated on the Gem mine by Coe & Co. Net returns of $60 per ton are received.

Idaho Springs, December 16.

SAN MIGUEL COUNTY

In a recent report the Wild Boy M. & M. Co. stated that during the year the branch adit had been extended 85 ft. in 'solid formation.' The adit was cleaned out to a point 400 ft. beyond where a large cave-in occurred. A drift was driven 85 ft. on a new vein. Another claim was located, making a total of eight claims and a millsite. New rails and tools were purchased and the company was $228 in debt. In accordance with the by-laws, work was stopped. In 1912, it is hoped, a 10-stamp mill may be erected. W. M. Herrington is manager for the company, which has its principal office at Pueblo.

TELLER COUNTY

The ores formerly going to the plant of the U. S. R. & R. Co. have been diverted to the Golden Cycle (cyanide) plant for the present, and the following open rates announced, as compared to the Standard rate of the shut-down:

MAP OF COLORADO.

Per ton.	Freight and treatment.	Standard rate.
Up to $10	$4.00	$4.00
$10 " 15	5.25	4.50
15 " 20	6.00	5.00
20 " 25	6.50	5.50
25 " 30	7.00	6.00
30 " 40	7.50	6.50
40 " 60	8.50	7.00
60 " 100	8.75	8.00
100 " 150	9.75	....
150 " 200	10.75	....
200 " 250	12.75	....
Above 250	12.75	....

These rates show a considerable advance on ores carrying 1 oz. gold, the higher grades not mattering much, as they can go to the smelters and may, with the rejuvenation of the Portland mill, lead to a rate fight early in 1912.

Lessees on the Gold Dollar Con. M. Co.'s property and the company itself shipped a total of 1200 tons of ore last month.

It is rumored that the Granite Gold M. Co., of Cripple Creek, will pay a dividend of 1c. per share shortly before Christmas. The company, according to late newspaper reports, has not taken definite action, but has had a prosperous year.

IDAHO

Idaho County

L. K. Armstrong, of Spokane, acting for Eastern investors, has acquired a three-fifths interest in the Anaconda, Georgia, and New York groups of mining claims in the Ten Mile district, according to advices from Spokane, for $125,000. The three groups include 20 claims, partly developed. There is a 5-stamp mill on the Georgia group. The ore yields $14 to $16 per ton. The new owners will erect a modern ore-reduction plant.

Shoshone County

The Success M. Co. has announced a dividend of 1½c. per share, or $15,000 in all, payable the latter part of December, making a total of $75,000 for 1911. Mr. Samuels, president of the company, says the monthly dividend disbursement will be $10,000 in 1912. Prior to the financial flurry in 1907 the company paid four dividends, aggregating $60,000. Smelter returns for a car of silver-lead-copper ore, says a report from Spokane, shipped by the Caledonia company, operating at Wardner, showed 486 oz. silver, 16% copper, and nearly 50% lead. Rapid progress has been made in development work in the new main working-adit since the bad ground in the hanging wall of the Osborn fault was passed.

Robert Scheffels, president of the Jack Waite Mining Co., has announced in Spokane that a lower adit will be driven through the first orebody. The company is installing an 80-hp. gasoline engine, air-compressor, and other apparatus, after which a concentrator will be erected. The company has $25,000 worth of ore on the dump. Forty men are at work. Workmen are erecting a 150-ton concentrator and installing a 100-hp. gasoline engine at the Black Horse mine. The Bear Top M. Co. also is erecting a 60-hp. gasoline engine and additional machinery for air-compression. Two hundred and fifty tons of ore per month is now being mined by the company and the capacity will be largely increased by the improvements.

Jurors in the District Court at Wallace, after sixteen hours' deliberation, sustained the claim of the Pittsburg Lead M. Co. to apex rights and refused to grant damages to the owners of the Monarch claim. Stockholders of the Nipisic Mining Co., headed by F. E. Goodall, of Spokane, have provided a fund of $20,000 to develop the property which adjoins the Amazon-Manhattan on the east and is separated from the Hercules mine by one claim. E. P. Spalding, of Spokane, general manager for the Coeur d'Alene North Fork M. & S. Co., announced, on returning from an inspection of the property, that the Monarch mine, near Murray, contains two large ore-shoots in parallel veins on the 1400-ft. level. One occurs in the original Monarch vein and has been developed all the way from the surface.

MINNESOTA

This State received last year, as royalty on iron ore shipped from State land, $214,717, a reduction of $142,444 from the sum received the preceding year. The State owns 20 mines.

MONTANA

Lincoln County

(Special Correspondence.)—With the object of constructing a smelter at or near Libby, building a railroad, and to further develop the Snowshoe mine, the Montana Smelting Co. has been organized and has taken over the holdings here of the Pacific Coast Smelting, Refining & Mining Co. The latter company purchased the Snowshoe mine about a year ago and has been operating steadily since that time. E. H. Wilson, consulting engineer to the company, who has the work at the mine in charge, states that the proposed work involves the expenditure of about $2,000,000, and it is the company's desire to build the smelter at Libby, providing arrangements can be made with land owners so that the company can be assured of not being harrassed by damage suits after the plant is in operation. Mr. Wilson gives it as his opinion, however, that the ores in this part of the country will cause absolutely no damage to the valley, as there is no arsenic in them.

The work of sinking the shaft is still in progress at the mine and a station will soon be cut 150 ft. below the 450-ft. level. As soon as this station is cut, drifts will be run north and south and another 150 ft. of stoping ground will be opened.

Libby, December 14.

(Special Correspondence.)—Paul D. Pratt, mining engineer, returned Friday from the California-Montana Placer Mining Co.'s property on Libby creek, where he spent several days in laying out the pipe-line for the big hydraulic plant that is to be constructed. W. H. Graham, of San Francisco, who is at the head of the enterprise, expects to have the plant ready by April 1. The steam drilling-machine is now being operated, and prospecting will be carried on throughout the winter. E. M. Sanders is in charge of this work. The company has contracted for 880 acres of land on Libby creek.

In addition to the big plant which is being constructed by the California-Montana Placer Mining Co., two others will be in full operation, the Libby Placer Mining Co. and the Comet Placer Mining Co., both hydraulic properties.

Libby, December 17.

Silverbow County

(Special Correspondence.)—The Butte-Ballaklava company will reach the depth of 1600 ft. soon after the first of the year. The sinking of the shaft from the 1400 to the 1500-ft. level was completed a couple of weeks ago.

The Tuolumne surface plant is all in position and nothing remains now but the adding of a few finishing touches. As soon as everything is working smoothly the output of the mine will be increased to about 250 tons per day. At the same time sinking, which was discontinued after the shaft had reached a depth of 1800 ft., will be resumed and the shaft carried to a depth of 2000 feet.

The Anaconda mine will not be in operation until after the first of the year. When the re-timbering of the shaft was completed from the surface to the lowest level, a short time ago, it was thought that ore hoisting could be resumed after the shut-down of over two years, but other improvements and repairs were found necessary, and it will be probably the middle of January before work is started up.

The experiments now going on in the North Butte mine for the purpose of demonstrating the practicability of operating the drilling machines by electricity have reached the stage where it is stated that it is only a question of a few weeks when arrangements will be made to equip all the machines with electricity. Besides accomplishing at least twice the work in a given time the cost of operating will be considerably reduced.

Butte, December 16.

John Farson, E. A Clark, and Francis Hamilton, according to late reports, have constituted themselves a committee to receive deposits of La France Copper Co. bonds, interest on which has been defaulted since January 1, 1908. The company's funded debt amounts to $2,000,000, interest on which is guaranteed by the United Copper Co., which offered its notes in July 1908, due July 1, 1909, and later notes due January 1, 1911, for unpaid coupons of the La France company due January 1 and July 1, 1910. F. A. Heinze is quoted as being favorable to the action. The members of the committee are all of New York. The company's assets chiefly have been the Lexington mine, near Butte, and the concentrator at Basin, Jefferson county.

NEVADA

Clark County

A new leasing company is being organized to develop the Quintette property, states a recent report from Searchlight. It will be known as the Colorado & Nevada Leasing Co. H. G. House will be general manager for the company.

Esmeralda County

It is rumored that the Florence Goldfield M. Co. is to erect another mill in the near future. T. D. Lockhart, of the Florence Goldfield company, is reported to be considering the Homestake-King mill at Rhyolite.

Twelve leases have been granted by Jordan Bros. on property at Antelope Springs. Downer Bros, assayers of Goldfield, have taken a lease on adjoining property.

HUMBOLDT COUNTY

Shaft sinking was started last week at the Limerick property in Rochester canyon. The Champion group, Jackson mountains, owned by F. W. Ackerman and Ed. Christianson, will start shipping copper ore in the near future.

It is reported that in the spring a mill will be erected on the Wam Pah property, formerly known as the Indian Ike, near Black canyon. An adit has been started. The mine is owned by Wright, Sullivan & Hunter, states a recent report from Lovelock. H. H. Hunter is manager of the property.

LINCOLN COUNTY

Newspaper reports state that the cross-cut on the 300-ft. level of the Pioche Demijohn recently penetrated the manganese orebody explored on the 200-ft. level. Another manganese orebody was traversed for 15 ft. Shipment of ore is prevented only by lack of railroad connection. W. E. Bailey is superintendent of the property.

LYON COUNTY

Reports from Yerington state that the greatest deposit of native copper yet found in the district was discovered last week on the 600-ft. level of the Nevada Douglas mine. Lumps of copper 98% pure and weighing up to 500 lb. have been removed. South of this native copper a drift has penetrated sulphide ore assaying 6 to 17% copper.

NYE COUNTY

(Special Correspondence.)—Large quantities of lumber is arriving for the Associated mill, and it is expected to have the frame in place within a few weeks. Machinery, tanks, and other equipment is reported on the way. The War Eagle mill has about completed the crushing of a shipment of ore from the Jumping Jack, and is about to start on 170 tons from Union No. 9. About 1100 tons from the Poak-Steen-Cicala lease on Big Four was recently crushed. With the crushing of the Union No. 9 shipment the mill will close until several repairs can be completed. The Big Four M. Co. has closed a deal whereby it gains a controlling interest in the Gold Wedge company. The transaction places the Big Four in a commanding position in the district, as it already owns the rich Big Four and Joker properties. The Mineral Hill management reports mining good-grade ore in the east drift from the shaft. The lower adit is progressing at the rate of about 6 ft. per day. The White Caps lease sent 1000 sacks of high-grade ore to the Western Ore Purchasing plant at Millers. The shipment comprises about 40 tons, and is said to average $60 to $80 per ton. The Steffner Con. lease has its shaft down 150 ft., with sinking progressing steadily. The steam compressor and hoist will in future be electrically operated. At the 100-ft. level connections will be made with the old workings.

Manhattan, December 14.

D. D. Sullivan, of Globe, Arizona, Frank Dick and A. L. Hill, of Los Angeles, and R. E. Pruesser, of New York, are about to organize a company, says a Goldfield report, to develop the Albion Millett mine, near Millet, which they recently purchased. The company is to be known as the Albion Millett Gold Mining Company.

The Tonopah M. Co. has declared its regular quarterly dividend of 25% and an extra dividend of 15%, payable January 20. The Tonopah M. Co. in November made a profit of $172,316, from 14,799 tons of ore which assayed on the average $20.71 per ton. The Tonopah Belmont made a net profit of $156,460 from 7807 dry tons milled and 2730 tons sent to the smelter. The North Star M. Co. has levied an assessment of 2c. per share to place it on a producing basis. On the 500-ft. level of the West End Consolidated mine an improvement in the ore was noticed last week.

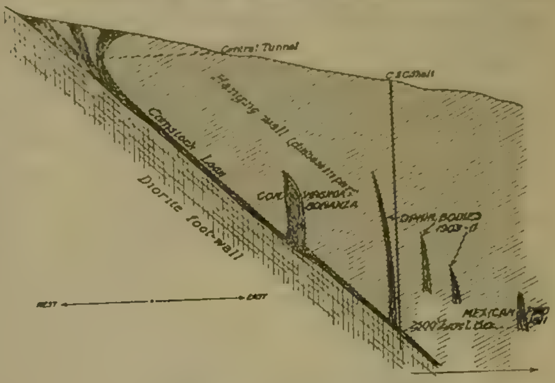
The production for the Tonopah district last week is thus summarized by the *Tonopah Miner:* The Tonopah M. Co. sent 3500 tons, the Belmont company 2450 tons, the Montana-Tonopah 1050 tons, the Tonopah Extension 980 tons, the West End 475 tons of ore and 325 tons of old tailing, making the total production for the week 8455 tons, the estimated value being $211,575.

A. S. Dingee, of Fort Worth, Texas, one of the stockholders who purchased the mine and mill of the Homestake-King company at Rhyolite, announced recently that by this action the stockholders who did not participate in the purchase are 'down and out' as far as the company is concerned. Economical operation that will pay for development will be attempted.

The Barcelona Mines Co. has been organized to develop six unpatented claims adjoining the old Barcelona mine, ten miles north of Manhattan. The company also has an option on the two unpatented claims of the Barcelona mine, owned by Eugene Locks. The company was formed through W. G. Lovie.

STOREY COUNTY

The production last week of the Comstock mines is summarized as follows by the *Virgina Chronicle:* The ore production from the Comstock mines, as reported today for the past week, shows a total of 1048 mine cars, giving a gross assay value of $24,528.86. The Mexican company output was a few cars saved here and there from development work. The production of the mines was as follows: Ophir, $18,525.78; Mexican, $3203.08; Crown Point, $2800; total, $24,528.86.



CROSS-SECTION OF COMSTOCK LODE.

The Mexican mill will be ready for a test run in the near future.

WASHOE COUNTY

Unusually rich lead sulphide ore was discovered last week in the Arkell mine, the Currie Wheeler shaft, and the McCart-Ball lease, all the property of the Nevada United company, states a recent report from Wedekind district.

WHITE PINE COUNTY

Construction work on the new Boston-Nevada mill in Spring valley will be started in the near future, and the machinery will be put in place on delivery. A few men are working in the mine, at Osceola. F. D. Goody is general manager for the company.

The water in the Giroux has been lowered to below the 1350-ft. level. The pumps on the 1200-ft. level are being tuned up for operation. Work is progressing satisfactorily on the railroad to connect the Morris No. 2 shaft with the concentrator. The hoisting plant is in place and the head-frame is partly erected.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Ernestine M. Co.'s first clean-up for December is being smelted. Last week 600 tons of ore was milled, producing 56 sacks of concentrate. Rich ore showing flakes of gold is coming from the new orebody, which is yielding a high-grade mill-ore for its entire width of 20 ft. The new 10-stamp battery is now in commission. The assembling of the De La Vergne high-compression oil-engines is progressing rapidly, under the supervision of an expert from the factory.

A total of 53 ft. of development was done during the week by the Oaks Company. Forty tons of ore was sent to the Deadwood mill.

More machinery for the Socorro Mines' new power plant was delivered during the week. The mill treated 1050 tons of ore the past seven days.

It is reported that the Cooney mine of the Mogollon G. & C. Co., above the adit level, has been leased for a period of two years, one of the conditions being that the lessees erect a small mill for reducing the ores.

The contract for driving on the vein at the 200-ft. level of the Trilby group has been completed.

Mogollon, December 15.

SOUTH DAKOTA

Lawrence County

(Special Correspondence.)—Fred Straub has taken a contract to complete the Black Hills smelter, at Galena, by February 1, and has a crew of men at work on the finishing touches. Owing to financial difficulties work was suspended for a time, but nearly all the machinery and material excepting electric motors is either at Galena or Deadwood. The motors have been ordered from the factory, for immediate delivery. The initial order for coke has been placed, 600 tons of Connelsville being the order given.

The Custer Peak M. Co. is retimbering the shaft down to the water-level, a distance of 80 ft. Below that point, to the bottom, 300 ft., the timber is believed to be in good shape. As soon as the new timbering is completed the shaft will be unwatered and development continued on the copper vein which gave encouraging results when opened two years ago.

John Hahne has leased the property of the Minna M. Co., at Galena, and will open it to ship ore to the smelter. The ground adjoins the Golden Crest property, and has a showing of porphyry ore assaying from $8 to $72 per ton.

The adit to connect the Glory Hole workings, on the Evans Consolidated ground, has been completed, and a most encouraging feature was the finding of 20 ft. of milling ore. A sample from the floor of the adit gave returns of $12 per ton, but it is not expected that the entire body will average this amount. Plans have been completed for the repairing of the Lexington Hill mill, recently bought by the Evans company, at a cost of $2500. It is hoped to have the plant, with 20 stamps, running early in the spring.

The New Reliance company has purchased ten stamps from T. R. Griffith, at Keystone, and will install them immediately in the mill at Annie creek. The mill has been running six months.

Deadwood, December 15.

UTAH

Juab County

In a statement to stockholders the Tintic Standard M. Co. announces that since the resumption of development last July, 555 ft. of work has been done, mostly by contract. Small orebodies, assaying from 11.8 oz. silver and $1.20 gold to 51% lead, 91 oz. silver, and $5 gold per ton were found. An assessment was levied for further development.

Salt Lake County

Rumors from Salt Lake City state that Yampa Smelting company of Bingham has discontinued shipping ore. Official confirmation of the report is lacking.

Utah County

The Hiawatha M. Co., capitalized at $100,000, with 1,000,000 shares, par value 10c. each, has been organized to develop property in the Provo district, including two unpatented lode claims, the Teddy and the Iona. Jesse Knight is president of the company, which has its main office at Provo.

WASHINGTON

Spokane County

Engineers and operators from districts throughout the Northwest, including the provinces of British Columbia and Alberta, and the Alaska and Yukon territories, will meet at Spokane, February 15 to 17, to organize an international mining congress. The Spokane Mining Men's Club, the Spokane Chamber of Commerce, and the Inland Empire Federation of Commercial Clubs will be hosts. The sessions are to take place in the State armory, where there also will be exhibits of ores and machinery. The committee in charge is composed of L. K. Armstrong, J. T. Omo, W. W. Gifford, J. C. Haas, and J. W. Turner of the mining club.

CANADA

Ontario

La Rose shareholders were hoping for a partial distribution of the company's surplus of something over $1,500,000, but no action was taken at the regular quarterly meeting, when the regular dividend of 2% was declared. Possibly the La Rose management has it in mind to do something with the various Porcupine ventures in which it is interested. The Temskaming shareholders have voiced some loud protests in regard to the purchase of a control of North Dome by the Temiskaming, but have been told in reply that North Dome is sure to develop into a profit-earner for the shareholders, if the board can be allowed to carry out its plans. Temiskaming, however, has been showing a steady decline in the market, rather indicating that present stockholders are far from approving the plans of the board and prefer getting out rather than waiting for dividends to come from the Porcupine property.

Yukon

Telegraphic despatches from Dawson state that a rush is on for the head of Sixty Mile river as the result of the discovery by John Matson of unusually rich ore. Matson is said to have panned 2½ oz. of gold from a bedrock space 5 by 8 ft. The creek on which the gold was discovered is 20 miles long and has several tributaries. The district is close to the Alaskan boundary.

MEXICO

Chihuahua

Press despatches state that the mines of the Cusihuiriachic district are quite active, although only two are shipping. These, the Promontorio and the Princessa, have a combined output of about 3000 tons of ore per month, the ore assaying 700 to 800 oz. of silver per ton.

The Cusi Con. M. Co. will start development on the Consolidada No. 2 property in the near future. The Consolidada No. 1 has been unwatered. The shaft is 340 ft. deep. As soon as a hoist can be erected shipping will be started. The same company already has started work at the Elisa mine.

Sonora

The Cananea company in November produced 5,750,000 lb. of copper, against 6,100,000 lb. in October. In the production is included the concentrate handled for the Ray Con. Copper Co. A new incline tramway is being installed at the Puertocitos property. At the Veta an ore-sorting apparatus, similar to that used at the Sierra de Cobre, is being placed.

The Catalina No. 2 shaft of the Calumet & Sonora M. Co., at Cananea, has been closed down indefinitely.

The Cajon mine, forty miles west of Noria, will start its cyanide plant and mill in the near future. The property recently was taken over by Colorado investors. The Mina Mexico smelter is working full blast and the mine is active. The Oputo M. Co. soon will start development work at the Waldorf, near Oputo, Moctezuma district.

NICARAGUA

(Special Correspondence.)—The first shipment of gold bullion to the United States from the Panama Mining Co.'s property in the Piz-Piz district was made November 5.

San Pedro, November 9.

COLOMBIA

C. J. London, of Philadelphia, is on his way to the properties of the Colombia Consolidated Goldfields, Inc., on the Cauca river, Republic of Colombia. The company's engineer has cabled that work with Keystone drill on the properties bears out the opinion previously expressed of the excellent gold content of the gravels.

Book Reviews

Any of the books noticed in these columns are for sale by or can be procured from, the Mining and Scientific Press

A Manual of American Mining Law. By A. H. Ricketts. Pp 186 ; xiv. Scientific Book Publishing Co., San Francisco, 1911. For sale by the *Mining and Scientific Press*. Price $4.25, postpaid.

Convenience of use is an important factor in the worth of a book, and Mr. Ricketts has evidently kept this factor in mind in preparing a volume to add to the already considerable number of handbooks of mining law, and has well indexed his material in addition. The book is exceedingly concise in its treatment of the subject, and might indeed almost be called a dictionary of citations. An interesting feature of the volume is the preface, written by Charles G. Yale, the son of the author of the first book dealing with American mining law.

Thermodynamics of the Steam Turbine. By C. H. Peabody. Pp. 282; ill. John Wiley & Sons, New York, 1911. For sale by the *Mining and Scientific Press*. Price $3.

Steam turbines have grown immensely in importance in recent years, especially with their widening application in naval engineering, and the extent to which this is true is well illustrated in the appearance of so specialized a volume as the one under review. The author, who is professor of naval architecture and marine engineering in the Massachusetts Institute of Technology, has prepared the work for the use of his own classes, but the scope of the work is somewhat wider than might be inferred from the title, and mechanical engineers engaged in the design of related types of engines will find much of interest in so complete a presentation of the subject.

Practical Gas and Oil Engine Handbook. By L. E. Brookes. Pp. 192; ill. Frederick J. Drake & Co., Chicago, 1911. For sale by the *Mining and Scientific Press*. Price $1.

This little volume, of pocket size, has been prepared to present in a lucid and practical manner, avoiding technicalities so far as possible, information regarding the operation and care of gas, gasoline, and kerosene engines. Mr. Brookes, who is already known as the author of works on the construction of gasoline motors and the construction and operation of automobiles, is well qualified for this task, and the many engineers who, without any special training, are called upon to operate gasoline and gas engines will be especially grateful for the concluding chapter, which discusses gas-engine troubles and presents briefly the more important features of the care and operation of engines of the explosion type.

Searchlights on Some American Industries. By James Cooke Mills. Pp. 299; ill. A. C. McClurg & Co., Chicago, 1911. For sale by the *Mining and Scientific Press*. Price $1.50 net.

The rapid growth of industry during recent years brings about such rapid and sweeping changes that the members of professions often find that unrelated lines of work develop so rapidly as to prevent 'keeping up' with them. The popular magazines and some weekly journals endeavor to meet this need by the publication of semi-technical articles dealing with various industries, but which from the nature of the circumstances under which they have been prepared, not infrequently are marred by errors of fact. Mr. Mills has endeavored to present a volume which, by care in its preparation, would be free from such defects. Just what has been the guiding principle in selecting topics for discussion is not perfectly obvious, but the treatment of those chosen is good, and the book is well illustrated. It is published at an opportune time, and will be useful as a gift book for engineers.

Notes on the Later Cenozoic History of the Mohave Desert Region in Southeastern California. By Charles L. Baker. University of California Publications, Bulletin of the Department of Geology. Vol. 6, No. 15, December 2, 1911. Pp. 50. Ill., insert. Berkeley, 1911.

Physical and Chemical Properties of the Petroleums of the San Joaquin Valley of California. By I. C. Allen and W. A. Jacobs. With a Chapter on Analyses of Natural Gas from the Oil Fields of Southern California. By G. A. Burrell. Bureau of Mines Bull. 19. Pp. 60. Ill., index. Washington, D. C., 1911.

Annual Report of the Smithsonian Institution, 1910. Pp. 688. Ill., insert map. Washington, D. C., 1911. This report is in its usual form of a brief review of the work of the Institution, including the report of the Secretary and the proceedings of the Regents, supplemented by some 500 pages of technical papers of much interest, chiefly long abstracts of important papers published in the proceedings of foreign scientific societies. Many of these are of the highest importance and of great general interest. It is unfortunate that they are included in what has the appearance of a dull report on business affairs; if this portion of the volume were published separately in more attractive form its usefulness would be greatly increased. The paper by C. E. Munroe upon the testing of explosives will have the greatest technical interest to mining engineers.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

E. H. Mead has gone to New York.

M. P. Boss is at Hotel Argonaut, San Francisco.

C. W. Merrill has returned to San Francisco from New York.

J. E. Spurr has become vice-president of the Tonopah Mining Company.

William Hawxhurst was recently at Salt Lake City and has returned to California.

Bayliss Clarke, superintendent of the Lightner mine, was in San Francisco this week.

F. Lynwood Garrison has gone to Arizona and will reach San Francisco about January 1.

Alexander Leggat recently left Butte for Patterson Creek, Idaho, on professional business.

S. T. Wellman is in the hospital at Redding on account of a broken leg. He is recovering as rapidly as could be expected.

W. J. Loring, who recently went to Burma to inspect the Burma Mines, Ltd., expects to return to London early in February.

Edmund Juessen has resigned as manager for the Pittsburg-Silver Peak, and will devote his whole time hereafter to consulting work.

George H. Garrey has discontinued private practice and accepted a position as geologist for the American Smelting & Refining Company.

George D. Dimmit has left the Goldfield Consolidated Mines Co. and is at present associated with Rex W. Dunlap & Co. at Phoenix, Arizona.

C. J. London has left New York on his way to the properties of the Colombia Consolidated Goldfields, Inc., in the Republic of Colombia.

W. P. Jennings, manager for the Grand Gulch M. Co., operating in Mohave county, Arizona, has returned from the property to Salt Lake City.

G. W. Heintz, general manager for the United States Smelting, Refining & Mining Co., has returned to Utah from a trip through Arizona and California.

James A. Force has been made consulting engineer for the German Gold & Uranium Mining Co., with offices at Philadelphia and Denver, the mine being at Quartz Hill, Gilpin county, Colorado.

W. W. Wishon has resigned the management of the Austin Manhattan Con. M. Co. at Austin, Nevada, and is spending the holidays at Butte, Montana, where he was formerly for many years.

Obituary

R. W. Hines, who died of pneumonia at El Paso on December 14, was born at Toledo in 1884, and had practised as a mining engineer in the mining districts of Sonora and Chihuahua, having lately been superintendent of the West Coast Mining & Smelting Co., leaving there to engage in [illegible] in El Paso. He was widely known throughout Mexico.

John B. Fleming, who died at Reno, December 17, from the effects of a fall, was a mechanical engineer well known in mining and metallurgical circles throughout the country. For many years he was chief constructing engineer for the Joshua Hendy Iron Works of San Francisco, and built the Silver King milling plant at Park City, Utah. Later he built the Nevada Consolidated mill at McGill, and the Goldfield Consolidated mill, Goldfield, Nevada, his latest achievement being the Nevada Hills mill. He was about 45 years of age; a kindly, generous, and lovable man. His ability as a mechanical engineer had won wide recognition.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press

Judicial Notice of Coal Veins

Judicial notice is taken of the different geological strata of coal in each county and of many other facts connected with coal mines and their operation. So judicial notice is taken of the fact that a detached stone 7½ ft. long, 3 ft. wide, and 18 in. thick, situated in the roof of an entry to a coal mine, can be carefully secured or taken down, as to hold otherwise would be ignoring the law of gravitation.

Princeton Coal Mining Co. v. Howell, (Indiana), 92 Northeastern, 122. June 1910.

Injury to Miner—Pleading

A complaint to recover damages for an injury to a miner by the falling rock from the roof of a mine entry was held sufficient where it alleged that the timbers which upheld the roof at the place where rock fell were weak, broken, and insufficient to sustain the roof, and that the owner and operator of the mine had knowledge of the defective and dangerous condition thereof, and for more than ten days prior to the day of the accident knew that the roof was liable to fall and injure the employees who were required to pass along such entry, and it was not necessary to aver that the defect complained of could be remedied, as the court takes judicial notice that a structure once made can be repaired.

Princeton Coal Mining Co. v. Howell, (Indiana), 92 Northeastern, 122. June 1910.

Statutory Duty of Mine Operator

The statute of Indiana (Burns' Ann. St. 1908, section 8580) requires the operator of a coal mine to make a dangerous place in a mine safe, and prohibits the employees from entering such a place until it is safe, but excepts such persons as are engaged in the work of making the place safe. By this statute the duty is imposed upon the mine boss or operator to see that all loose slate, coal, and rock overhead in entries where miners have to travel to and from work, shall be taken down or carefully secured, and until the place is made safe no person shall enter such unsafe place except for the purpose of making it safe. While this prohibition is general in its terms, yet the subsequent provision authorizing the mine boss to give permission for miners to return to work therein after the repairs are made, shows an intention to invest the mine boss with power in that particular, and there is no doubt of his authority and duty to order miners excluded from the unsafe place.

Princeton Coal Mining Co. v. Howell, (Indiana), 92 Northeastern, 122. June 1910.

Property Subject to Miners' Liens

The statute of Oregon provides that when two or more mines are owned by the same person or corporation and worked through a common shaft or tunnel, or at one mill, or other reduction works, then all such mines, and all roads, tramways, trails, flumes, ditches, or pipe-lines, buildings, structures, or superstructures used or owned in connection therewith, shall be taken and deemed as one mine. And in an action to enforce miners' liens the words "roads, tramways, flumes, ditches, or pipe-lines" were held to include such appurtenances though not situated upon the mine, and that the term "upon any mill-site or mill used, owned, or operated in connection with such mine," had reference to mill-sites or mills not situated on the mining property, so that a miners' lien notice need not state and it is not necessary to prove that the labor for which the lien is claimed was done on the mill or building on the mine.

Washburn v. Inter-Mountain Mining Co., (Oregon) 109 Pacific, 382.

Company Reports

THE BUNKER HILL & SULLIVAN M. & C. CO.

This company, during the year ended May 31, mined 438,290 tons of ore at a total cost of $[illegible], a lower total cost than has been attained for the past four years, notwithstanding the increased expenditure for hoisting, pumping, and higher prices of many materials and supplies. The lower grade of the ore and the continued low lead and silver prices brought the operating profit to about the same figures as for the preceding year. The profit for 1910-1911 was $1,110,315, as against $1,200,552 for 1909-1910. The highest profit was for 1906-1907, $2,627,778. While extensions to the plant and other improvements, together with cleaning up the remaining Federal M. & S. Co. litigation expense, caused heavy financial outlay, the net surplus for the year is $870,986, or $75,011 more than for the preceding year. The 438,290 tons of ore mined was valued at $3,307,393. The net smelter returns for the year amounted to $2,051,664. The concentrators treated 436,240 tons of ore, an average of about 1270 tons per 24 hours of actual operation. The tailing-mill treated, during 142.9 days of operation, 101,300 tons of tailing, at a cost of $14,009. Dividends paid during the year amounted to $1,062,750, as against $668,100 for 1909-1910. The dividend disbursements during the life of the company reach a total of $12,701,850. The development work exposed new ore in quantity exceeding the tonnage of the ore produced, and the material condition of the mines and property and the outlook for the future are reported excellent.

THE EL ORO MINING & RAILWAY CO., LTD.

This company during the year ended June 30 produced 360,294 tons of ore, which yielded bullion worth $2,389,349, or at a rate of $6.63 per ton. During the preceding year the output was 316,138 tons, which yielded bullion valued at $2,562,705, or at a rate of $8.10 per ton of ore. The recovery for the year just closed was 87%, against a recovery of 91% in 1910. The cost was reduced from $4.93 per ton, in 1910, to $3.90 per ton in 1911. For about the last three years the ore has been all-slimed and cyanided. A. F. Main, manager for the company, is making further improvements, and it was stated by R. T. Bayliss, chairman of the annual meeting, held in London, September 26, that these improvements may result in the treatment of ore yielding $4.50 per ton. Disturbances in Mexico reduced the profit from the railway from $124,254 in 1910 to $103,120 for the year just closed. The ore reserve on June 30 was estimated at 484,139 tons, averaging $9.10 per ton in gold and silver, against 441,639 tons averaging $9.50 per ton in the preceding year. This ore is in the San Rafael, San Patricio, and Descubridora veins. Work is being done also on the No. 4, or Victoria, vein in the Somera property, which it is believed will be an important source of production. There is an accumulation of tailing amounting to 450,000 tons, which on re-treatment, it is believed, will yield a net profit of $700,000, or $1.50 per ton. The Suchi Timber Co. had an output of 1,574,000 ft. per month and brought a net profit of $21,000.

The report shows a "total realized profit" of £216,430. Adding the amount brought forward from the last account, the report shows an "available profit" of £306,476. The sum of £11,532 has been set aside for the income tax on profits, and £13,059 for permanent improvement and railway construction during the year. For depreciation of equipment, £25,000 has been written off. Dividends No. 20 and 21, 1s. 6d. each, account for a distribution of £172,125, leaving a balance of £84,759. On June 30 the company had £178,000, in round numbers, in cash and short loans. Deducting unpaid dividends and other debts, there was £75,000 in cash in the treasury, against a balance of £84,759, and the company also had £21,925 worth of bullion in transit. The El Oro company's mine is 100 miles northwest of Mexico City.

Commercial Paragraphs

Constant Meese, president of Meese & Gottfried Co., has just returned to San Francisco after an extended trip along the Pacific Coast, made for the purpose of studying harbor and docking facilities. He was accompanied on the trip by W. C. Conant, manager of the San Francisco house; Mano A. Zan, northwest manager for the company; I. Boyd, manager of the Los Angeles branch; H. E. Gearon, manager of the Portland branch, and C. A. Magnuson, manager of the Seattle branch. The party spent some weeks making a careful survey of the waterfronts, all the way from Los Angeles to Vancouver, B. C., accessible to the various coast cities, the object being to prepare for the proper handling of the large increase in business which is coming to the different Coast ports on the opening of the Panama Canal. While in Seattle the party enjoyed meeting some twenty-five of its leading machinery men at the Arctic Club. The Meese & Gottfried Co. is one of the oldest and best known firms on the Coast engaged in manufacturing and dealing in transmission, elevating, conveying, and screening machinery, and with the opening of the Panama Canal it anticipates a wonderful increase in the demand for this class of machinery. The recent trip was taken with the object of making the engineers of the company thoroughly conversant with the improvements proposed for the different seaports to care for the rush of new business certain to come to the Pacific Coast.

The Broderick & Bascom Loggers & Supply Co. of Seattle was incorporated with $50,000 capital stock by Charles E. Bascom, John K. Broderick, John J. Broderick, and Joseph D. Bascom of St. Louis, and H. J. Bailey of Alton, Illinois, to conduct a special branch of the Broderick & Bascom Rope Co. of St. Louis business, and manufacture some specialties in Seattle, Washington. C. A. Stewart is president and manager of the Seattle corporation; H. J. Bailey is treasurer. L. G. Isaacson is vice-president and manager of the Aberdeen, Oregon, branch. They will handle all logger supplies and Broderick & Bascom wire rope in that section of the country.

Among recent orders for equipment received by the Dorr Cyanide Machinery Co. are eight duplex classifiers and eight thickeners for the new mill of the Tonopah-Belmont Development Co. at Tonopah, Nevada; a classifier and thickener for the Portland Gold Mining Co. of Colorado Springs, Colo.; and two classifiers and one thickener for the Katchkar Gold Mining Co., Perm Government, Russia. This will make three Dorr classifiers and four Dorr thickeners in use by this last company.

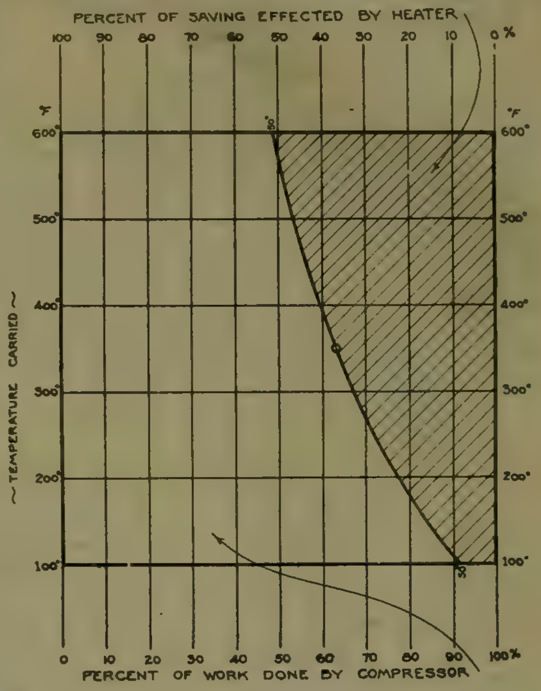
W. W. Merriam has been appointed the Mexico representative of the Oliver Continuous Filter Co. Before establishing a permanent office he will visit a number of mining camps in order to get a thorough knowledge of the Mexican situation. Engineers who are desirous of investigating the Oliver Filter can arrange for an appointment with Mr. Merriam by addressing the new offices, Rooms 704-5-6-7 Hooker & Lent building, San Francisco.

Charles E. Newmeyer, who for the past four years has been connected with the H. A. Riedel Investment Co. of Denver, Colo., has resigned to become vice-president of The W. A. Fisher Investment Co., with offices in the First National Bank building of that city. The W. A. Fisher Investment Co. is handling the financing of The Colorado-Highland Marble Co., with property in Pitkin county.

To take care of the rapidly increasing business, the Oliver Continuous Filter Co. has taken rooms 704-5-6-7 in the Hooker & Lent building. This building is in the heart of the machinery district, being at First and Market streets, directly across from the Mechanics' Fountain. The Oliver Continuous Filter Co. will be glad to welcome its many friends in the new offices.

C. E. Russell, formerly with the Traylor Engineering Co., has been appointed Assistant Sales Manager for the Hyatt Roller Bearing Co., of Harrison, New Jersey.

The Sterling Equipment Co. has recently placed on the market a portable compressed air reheater which has sufficient capacity to supply one drill, and automatically maintains the desired temperature of the air passing through it. This is accomplished by the burning of gasoline or kerosene directly in the compressed air as it is passing through the heaters. The fuel is injected into the combustion chamber in the required quantity by the current of air passing through so that the heating is automatically kept up while the tool is in operation and is discontinued when the tool is stopped. The mixture of fuel and air is ignited by an electric resistance coil or by a hot tube. It is stated that the only attention required is in the initial adjustment of the fuel valve to give the temperature desired. The heater marks a new departure and a distinct advance in the working out of one of the most important problems in connection with the employment of compressed air for general industrial purposes. The considerable increase of volume resulting from the heating or reheating of air after compression and transmission, and the slight fuel cost of such reheating are generally understood and many heaters have been devised for the purpose, but various objections have prevented their extensive adoption. Perhaps the most frequent deterrent has been in the intermittent character of air employment. Heaters which would give very good results when the current of air was flowing constantly through them, as in the driving of a pump, have not proved so satisfactory in connection with rock-drills or other intermittently operated tools. The economy resulting from the use of this reheater is shown in the accompanying efficiency chart.



—AIR ECONOMIZER CHART—
—STERLING EQUIPMENT CO.—

Catalogues Received

New York Engineering Co., 2 Rector street, New York. 'The Empire Tailing Elevator.' Illustrated. 6½ by 9¾ inches.

The Jeffrey Manufacturing Co., Columbus, Ohio. 'Jeffrey Power Transmission Machinery.' Catalogue No. 5. 142 pages. Illustrated. 6 by 9 in. This is a most complete catalogue, and besides full information about this company's product, contains technical information worth while. Typographically it is excellent, the illustrations and arrangement of tables, etc., showing much care.

EDITORIAL

TELEGRAPH, telephone, and cable companies will be put under the jurisdiction of the Interstate Commerce Commission, if the recommendations of that body be approved by Congress. The Commission has done effective work, and has used its authority wisely; the proposal seems an excellent one.

TORONTO is elated over the plan to make that city an ocean port by extensive harbor and canal improvements. This, the second largest city in Canada, is already an important railroad centre, and the proposal is an evidence of the notable growth of industry in the northland during the past decade.

CONVOCATION week is a notable feature of each year in the educational world. Washington, D. C., has been chosen as the place of meeting, and, beginning December 27, eleven sections of the American Association for the Advancement of Science, together with twenty-eight affiliated societies, have been in session.

GREAT BRITAIN is a good customer of the United States; over a billion dollars worth of goods having passed between the territory of the two countries during the ten months ended with October. Of this, the United States exported approximately two-thirds and imported one-third, a gratifying increase over previous years.

CAMP BIRD, though about to pass from the list of producing mines, will always be remembered by mining men as one of the most famous of its day. Much apocryphal history gradually becomes current regarding the great, whether men or mines, and we are fortunate in being able to present this week the story of the property by Mr. T. A. Rickard, who lucidly and interestingly relates events of which knowledge was born of participation.

CLOSER relations between Canadians and Americans in the Northwest are likely to be the result of the efforts of the members of the Spokane Mining Men's Club, now engaged in an endeavor to organize an international congress of mining men. All such meetings are necessarily productive of good, and the engineers of the Northwest show commendable energy and initiative which, we hope, will meet with a corresponding degree of success.

CONFERENCES of leaders are vastly more productive of results than public clamor, and the recent pourparlers between Mr. W. L. Fisher, Secretary of the Interior, and the Governors of a number of Western States, should be correspondingly effective. Mr. Fisher advocates the abandonment of the apex right, the abolition of power of attorney, and maintains that the essential requisite is the development of mineral resources. It begins to appear as though effective action regarding the mineral land laws would be taken at the present session of Congress.

EVEN Homer nodded at times, and technical journals are sometimes to be found 'asleep at the switch.' *The Mining Journal*, of London, for December 2 contains the following gem: "The largest dredger of the world has now been installed on one of the pits of the Ilse Mining Company, Limited, in Germany. Its buckets have a capacity of ½ cwt. each, and thirty-two buckets are emptied each week, representing an aggregate capacity of 960 cubic metres per hour. * * * This plant is stated to represent the extreme limit of usefulness for bucket chain dredges; not even brown coal pits have, so far, ever shown any scope for a higher capacity." Our German friends have a reputation for slowness combined with effective action, and their dredging achievement should add lustre to their renown.

COPPER producers had a merry Christmas indeed, with copper at 14¼ cents. What this means to some of the large enterprises is well exhibited in the report of Mr. Pope Yeatman upon the Braden Copper Company, where the estimate is made that each cent increase in the selling price of copper corresponds to an increase of 19.6 per cent in operating profit. Only a moderate further increase is desirable; high prices in the past have always been followed by periods of depression. The official figures of copper production for 1910, recently issued by the United States Geological Survey, give leading place to Arizona, with a production of 297,250,538 pounds, closely followed by Montana with 283,078,473 pounds, and Michigan with 221,462,984 pounds, these three States having furnished 74 per cent of the total output.

IN our 'Discussion' column this week, Mr. C. R. Gent contributes some observations upon the economy of 'cheap' labor. But, with due apologies to Mr. Gent, the problem is not quite according to his view, nor can it be so summarily concluded. Immediate success will not be the reward of dismissing all dollar a day men, and putting on eight-hour shifts at $3.50 per day, for a high-priced laborer can 'soldier' as well as an unskilled laborer can, with the added disadvantage that his time is costing the company more. The management of a company in the West, where exact figures have been kept over a long term of years, asserts unhesitatingly that the effective return per dollar of wage paid has decreased since the institution of shorter hours and higher pay. Doubtless many factors are concerned in this, but at any rate it is obvious that the results are not automatically beneficial. That a highly skilled workman can produce results impossible with unskilled labor is as unquestionable as that a lathe can do work impossible of accomplishment with hand tools. Whether it is more economical to buy and operate the lathe for work which can be done by hand tools, when the wage paid to the workmen is sufficiently low to allow comparison with lathe work, is a matter of business arithmetic. Obviously an individual solution must be obtained for each individual case, and it is hoped that its discussion may establish fundamental principles which will be of service to those called upon to manage enterprises under novel conditions of work.

PURCHASE of a controlling interest in the North Dome by the management of the Temiskaming Mining Company, of Cobalt, has resulted in open rebellion on the part of the Temiskaming shareholders, who are trying to unite to oust the officers who consummated the purchase. The Temiskaming has been paying a regular dividend, but about the time the announcement was made that the treasury surplus was to be used in the purchase of North Dome shares, announcement was also made that dividends would be suspended. Now, with the completion of the payments to be made and the development and equipment of the North Dome to be provided for, the Temiskaming shareholders look upon the suspension of dividends as wholly indefinite, and possibly permanent; wherefore the protest and a demand for a change in the management. Generally speaking, Porcupine is furnishing little of interest in the share market; there have been some sharp declines, as in Rea Consolidated, which sold at one time for $6.25 per share; recently it sold for $2.12½. What has so far been done in good faith in the effort to put legitimate mining enterprises on a sane and business basis, has been so vastly overshadowed by manipulation and by what is, at least from every appearance, downright misrepresentation, that the public at large has the impression that Porcupine is one gigantic paper promotion and stock-jobbing scheme. The 'flattening out' of Porcupine and the increasing gravity of the situation in Mexico leaves the East without a field in which precious-metal mining commands public interest.

Investment and Speculation

Human judgment is fallible, and it is hopeless to expect that the general public will ever be brought to make clear distinctions in matters which involve the exercise of judgment and technical knowledge, but it would seem as though the degree of confusion existing as to the distinction between investment and speculation, especially where mining enterprises are concerned, is entirely unnecessary. Yet the theoretical distinction is a simple one; investment is the placing of capital to secure income from its employment, while speculation is the investing of capital with a risk of loss in the hope of securing large gain. Obviously the one grades into the other, and the practical distinction may be at times difficult, yet in the majority of cases the reverse is true, and it is possible to at once say whether or not the enterprise in question involves any appreciable risk. The public prefers sweeping generalizations and regards the purchase of bonds as an investment and the buying of shares as speculation; the acquisition of a corner grocery as investment and the purchase of a gold mine where a ten-stamp mill is yielding good returns, as speculation. Yet it is clear, upon sober thought, that, for example, the expected growth of population in the neighborhood may fail to materialize and the profits of the grocery business may vanish, and that this is no more improbable than that the vein may be faulted or impoverished in depth. The element of risk is involved in both cases, and the degree of risk depends on the price paid and the degree of accuracy of the information available concerning the governing conditions of profitable operation. Similarly, the municipal bonds of a Chinese city at present would have but a speculative value, while the ordinary shares of a well established industrial enterprise are of stable value. Much is added to this confusion of mind by the popular writers upon financial matters, and in one of the popular magazines which maintains an investment department for the guidance of its readers, recently to a query as to the advisability of the purchase of shares in a well known gold mining company, the pious reply was made that the purchase of mining shares is speculation and the magazine in question never advised speculation. This would be amusing were it not seriously set forth for the guidance of investors, and were it not for the possibility that investors, duly warned of the pitfalls of mining finance, may be the more easily led into the devious ways of industrial speculation. Cant has always been unpopular, and is especially so in the twentieth century. And if generalizations are required, a sweeping one can be made: the investor who places his funds into any enterprise concerning which he has neither accurate first-hand information nor the advice of someone in whom unquestioning reliance can be put, is neither investing nor speculating, but 'plunging' in the most reckless manner. Guns and 'advice to subscribers' should be handled with caution, either may be loaded.

Two Famous Mines—II

By T. A. Rickard

In 1894 Thomas F. Walsh was running a little matte smelter at Silverton, and I had the pleasure of selling him pyritic ore from the Yankee Girl, at Red Mountain, for which mine I was then manager. Walsh badly needed siliceous material containing enough gold and silver to be a profitable portion of his smelting charge, to mix with the heavily pyritic ores he was receiving from Red Mountain. He examined and sampled a number of abandoned workings in the vicinity during 1895 and 1896. Among his enterprises was a small silver-lead mine called the Hidden Treasure, in Imogene basin. One day in the spring of 1895 I walked across the range from Red Mountain to Telluride and, missing the trail going to Savage basin, I found myself in Imogene basin. Seeing smoke arising, I went toward it and found a cabin in which dwelt the miners working in the Hidden Treasure. They shared their coffee and bacon with me and told me how best to go to Telluride. I was then a brassy shot from the future Camp Bird mine. At that time it lay undiscovered. Next year, in July 1896, Walsh, during one of his periodical visits to the Hidden Treasure, happening to see some pink spar in the talus at the foot of the cliff at the head of the 'basin' or mountain amphitheatre, told Andy Richardson, a worthy prospector in his employ, that the pink spar reminded him of Cripple Creek, where he had operated the Summit and Deerhorn, two mines belonging to W. S. Stratton and leased by him to Walsh. Here we have another link between the two great bonanzas. The pink spar was not fluorite such as characterizes the Cripple Creek ore; it was either rhodonite or rhodochrosite. Walsh told Richardson to have a look at the old 'tunnel'—the Gertrude—from which the spar appeared to have come. In the September following he examined these abandoned workings himself and broke some samples, which were sent to Ouray to be assayed. They contained several ounces of gold per ton. More samples were then taken and sent to Leadville for assay. Walsh was careful to keep the discovery quiet. He set to work to acquire the ground, buying abandoned claims on tax-titles, until he had consolidated a large property. He also located a claim called the Camp Bird next to the Gertrude and gave the name of this new claim to his consolidated property. In 1900 he owned 103 mining claims and 12 millsites, covering 941 acres altogether.

At that time Theodore Gross, through Charles S. Thomas, ex-Governor of Colorado, obtained permission for me to examine the mine on behalf of the Venture Corporation. I made a preliminary inspection in May 1900, the results being sufficiently satisfactory to warrant a detailed sampling, in which I was assisted by A. C. Beatty and F. H. Minard. John Hays Hammond, being then in Denver, came to see me and expressed an interest in the mine, but, learning that an option had been secured for my clients, he did not go to see it, as I undertook to introduce him to Frederick W. Baker, of the Venture Corporation, so that they might co-operate in the formation of an English company to exploit the mine. My examination was completed in July and showed $6,118,800 in reserve, the ore averaging 5 ft. wide and $48 per ton. Up to that time the cost had been $6.50 per ton. I appraised the mine at $6,000,000. At that date the mine had yielded $2,535,512 gross and a profit of $1,650,000. In August I went home to London. Mr. Walsh agreed to give the Venture Corporation a call on the mine for three months at $6,000,000. Messrs. Baker and Hammond set to work to raise the money. In September $6,500,000 was subscribed by Wernher, Beit & Co., J. B. Robinson, C. J. Hambro & Son, and other prominent London houses. In September (1900) a company was registered at Somerset House. The closing of the transaction was deferred until Hennen Jennings, with Mr. Hammond, could pay a visit to the mine on his way to California. Meanwhile F. W. Bradley had made an inspection and sampling, confirming my results most cordially. At the end of September Messrs. Jennings (representing Wernher, Beit & Co.) and Hammond reached Ouray. Mr. Hammond was ill, and abstained from making an examination. Mr. Jennings visited some of the neighboring mines and was intimidated by the poor showing in the bottom workings of the Tomboy, for this augured badly for persistence in depth at the Camp Bird. This was before the Tomboy acquired the Argentine. Mr. Jennings endorsed the correctness of my report, but decided that the mine was not worth the price. He cabled accordingly. The checks of the subscribers were returned to them. Walsh continued to operate the mine. Shortly afterward Mr. Jennings made him an offer, of $5,000,000, half cash and half shares. This was declined. Messrs. Hammond and Baker resumed negotiations, but it was not until April 1902 that they finally closed the deal. The company registered two years earlier then acquired the mine. In the meanwhile Walsh had extracted about $1,500,000 worth of ore from which he had made about $750,000 in profit.

LOOKING TOWARD OURAY FROM ABOVE THE CAMP BIRD MILL.

By the new deal Walsh was to receive $3,500,000 in cash and $500,000 in shares, making £801,163, and he was to obtain a further $2,000,000, or £400,000, in the form of a royalty of 25% on profits from ore not then considered sufficiently proved. He received the last part of this deferred payment before his death, in March 1910, so that he obtained a total of $6,000,000 for his mine. Obviously the second deal, except as to the deferment of $2,000,000, was no better than the first, for during the interval between the two deals Walsh extracted enough ore to yield him a profit of $750,000. Mr. Hammond was appointed consulting engineer and William J. Cox came from Aspen to take charge of operations. The mine did splendidly, paying 20% per annum on the 820,000 shares (of £1 each) issued. The nominal capital of the company, called the Camp Bird Limited, was £1,100,000.

In March 1906 a snowslide overwhelmed the mill and caused a conflagration, destroying the entire plant; but this was soon remedied by the erection of a better one. In depth the lode never looked promising (for geological reasons by no means obscure), and systematic exploration proved that the orebody did not persist, but the large extent of virgin ground above Walsh's workings westward proved most productive, as anticipated. The resources of the mine, however, showed signs of exhaustion in 1908 and an effort was made to acquire another property with the surplus that had accumulated. In 1909 an option on the La Blanca mine at Pachuca was obtained for $2,500,000, but the deal fell through; shortly afterward an option on an adjoining mine, the Santa Gertrudis, was obtained by Mr. Hammond from Don Carlos de Landero, for 9,000,000 pesos. The purchase was effected for the Camp Bird company, the commission paid to Mr. Hammond, who was then consulting engineer to the company, being $600,000 or £119,178, as was duly stated in the prospectus, issued in January, 1910. The Camp Bird company paid £922,131 for the Santa Gertrudis, receiving 1,155,815 fully paid shares in the Santa Gertrudis Co., Ltd., which was registered with a capital of £1,275,000. The examination of the Mexican mine was made by R. J. Frecheville, W. J. Cox, E. E. Chase, and F. J. Pope. The ore reserve was estimated at 462,826 tons, assuring a profit of £924,755 or $4,620,000. The orebody was stated to be 2500 ft. long (of which 1500 ft. was in Santa Gertrudis territory) and had been followed to a vertical depth of 1000 ft. The average width was 15 ft. and the average assay-value $23.25 per ton. At the time of purchase the mine was 1700 ft. deep, the bottom level being extended for half the length of the orebody. The estimates and allowances for ore only partly exposed were somewhat risky and the financial requirements compelled the Camp Bird company to stretch its resources, by issuing debentures, etc., but the mine has opened up well and placed the enterprise on an excellent footing. The new mill started to work in June, 1911. During the current year the Santa Gertrudis is expected to yield a profit of $1,000,000, and next year $1,750,000. The latest estimate of the ore reserve, by Hugh Rose, the manager, is 1,150,000 tons, from which a profit of £1,650,000 or $8,250,000 is expected.

Now we return to the parent mine, the Camp Bird. While steps were being taken to perpetuate the company the old mine was nearing its end. In May 1910 the ore reserve was estimated at 83,900 tons, to yield a profit of $1,420,000. During the ensuing year a profit of $1,095,000 was made, and $435,000 more remained. Thus new ore had been uncovered to the extent of $110,000. In the first four months (May to August) of the present fiscal year the mine yielded a profit of $400,000, and $230,000 was supposed to remain. On October 31 Mr. Cox telegraphed that the reserve, owing to further finds, assured $300,000 more profit. However, the end is now in sight, and unless something wholly unforeseen happens the mine will be finally exhausted during the current fiscal year, during which it will have yielded a profit of £150,000 or $750,000. Efforts have been made to acquire productive territory in the vicinity, but without success. In 1905 a bond was taken on the ground controlled by the Imogene Basin Gold Mines Co., and eventually the Camp Bird company acquired a large holding in compensation for the money spent in development, but no ore worthy of mention has been found. At the recent annual meeting on October 31, the chairman of the company, Arthur M. Grenfell, was able to boast that the Camp Bird had yielded gold to the value of £3,750,000 or $18,750,000, and up to April 30, 1911, the dividends have aggregated £1500,000 or $7,500,000, besides the £300,000 or $1,500,000 invested in the Santa Gertrudis. Adding the output and earnings under the former owner, the Camp Bird mine has yielded $22,785,500 gross, of which $11,400,000 has been profit. Thus the proportion of gain has been 50%, after paying for equipment. This is a superb record. In comparison with the Independence, it may be said that the original owner, Thomas F. Walsh, was a real mining operator, with previous experience at Leadville and Cripple Creek. He was a much abler man, in every way, than Stratton and managed the sale of his mine with conspicuous skill. That was one reason why the finance incidental to the formation of the company was not such as to cripple the mine or handicap the management. In John W. Benson the mine had an excellent superintendent under Walsh, and in William J. Cox it had an even more experienced manager under the company. Mr. Hammond remained consulting engineer until February 1911. For several years the supervision devolved on his former assistant, A. C. Beatty, who applied exceptional skill to the technical details. Among the directors is R. J. Frechville, a veteran among British mining engineers. Thus the Camp Bird did not lack for the best that experience and knowledge could contribute. The story of the mine is a credit to all concerned, and especially to the honorable and energetic man who first uncovered its hidden wealth.

Tin Production, Federated Malay States

By D. Milton Figart

The exports of tin and tin ore were the lowest since 1900, amounting to 43,863 tons, against 48,744 tons in 1909; the 1910 exports consisting of 9900 tons of block tin and 33,963 tons of tin in the form of ore. Higher prices, however, made the total value of the 1910 production greater than that of 1909, the approximate value at Singapore being $32,447,000 in 1910, and $31,711,440 in 1909. The average price per ton on the local market was $722.90 in 1910 and $648.81 in 1909. The number of men employed in the tin mines in 1910 was 170,361, compared with 184,699 in 1909. The Warden of Mines, in his annual report says:

"At the beginning of the year the better prices realized at the end of 1909 continued, though there was little in the statistical position to justify them, the visible supply at the end of January being larger than had been the case for several years. The tin-plate trade, which is said to consume two-fifths of the world's production, continued to flourish, the returns for the first seven months being beyond all record. In June, the visible supply was low, and there is no doubt that the drop in Federated Malay States production made itself felt on the market. In September there was a reaction, the demand dropping and the visible supply increasing. In October there were urgent demand for shipments to America, and speculators who had anticipated an increase in price had their operations assisted by the limited sources of supply and the increasing demand. In November the price continued to rise despite the rumor of the closing down of a number of tin-plate mills in America. In December the market remained fairly steady and the year closed with the statistical position good.

"The tin-plate tonnage has more than doubled since 1896, and though substitutes are talked of, nothing has so far appeared in a practicable and generally useful form which is likely to oust tin plate from its uses, and also, in this connection, it should be remembered that the decrease in tin exported from the Federated Malay States in 1910, as compared with 1909, practically amounts to 5000 tons, or nearly equivalent to 5% of the output from all countries."—*Daily Consular Report.*

The total production of sulphur in Sicily during the first six months of 1911 was 182,678 tons, against 185,825 tons during the corresponding period in 1910. On June 30, 1911, the total stocks of sulphur in Sicily were 527,965 tons, against 586,878 tons at the same date in 1910. The exports of sulphur during the first half of 1911 amounted to 287,410 tons, against 240,919 during the first half of 1910, an increase of 46,491 tons. In 1909 the production in the United States amounted to 274,000 tons, of which 239,000 tons, with a value of $4,432,000 was marketed. The exports that year amounted to 37,142 tons, with a value of $736,928, as against the 30,589 tons imported.

Disinfecting Miners' Dwellings

By W. H. Ross and R. C. Benner

The mining community is at a disadvantage in proper sanitary protection against disease. Miners form an essentially transient population, not alone from the nature of their calling, but also from a certain spirit of restlessness and a desire for new and better fields. The situation of the less well established towns is almost entirely dependent upon the ore deposits. At first everything is of a temporary nature, and sanitary conditions are entirely disregarded in the location of the houses. One family moves in when another moves out, with a total disregard of the state of health of the former occupants. This leads to the spreading of disease, which might be prevented in many cases by the proper use of disinfectants.

The principal agents which are efficient in the destruction of germs of all kinds are three: chemical disinfectants, heat, and light. Although the purposes for which chemical disinfectants are used are now generally understood, there is much popular misconception as to the value and limitations of the various commercial disinfectants. Most commercial preparations contain some true disinfectant, but often in such small amount that they are of little or no value for disinfecting purposes. In many cases this is due to the fact that they are produced by persons having little knowledge of sanitation, or of the principles of disinfection. With bacteria, as well as with animals, or the higher plants, a poison, to be effective, must be administered in excess of the limit of toxicity.

Many substances will prevent the development of bacteria, and as they may be used without destroying the tissues, they are therefore useful in preventing putrefaction or suppuration in the living body. Such substances, as boracic acid, salicylic acid, and others, when used for this purpose, are called antiseptics. A much smaller number of substances are more powerful in their action and are true disinfectants, that is, substances which will destroy the bacteria which are the cause of infection. The most important of these are formaldehyde, sulphur dioxide, carbolic acid, cresol, chloride of lime, and bichloride of mercury.

When disinfection is carried out by means of a gas, the process is called fumigation. Only two effective gaseous disinfectants are known: formaldehyde, and the sulphur dioxide formed by burning sulphur. It should be borne in mind that a sufficient concentration of the fumes of any disinfectant to kill the micro-organisms in the air must make the air entirely unfit to breathe. Consequently burning a small amount of sulphur on the stove; placing saucers of chloride of lime under the bed or about the room, or hanging up sheets dipped in some non-volatile disinfectant, are of little value. In the same way, medicated lamps or burning pastils are useless as disinfectants but simply act as deodorizers.

To thoroughly disinfect a room with sulphur, 3 to 5 lb. should be burned for each 1000 cu. ft. of space. This is best done by placing the powdered sulphur in an iron pot which is, in turn, placed in a vessel of water. This not only diminishes danger from fire, but also furnishes moisture to the air, thus making the gas more effective. Sulphur dioxide not only destroys the germs of infection, but is also fatal to animal life. It quickly kills rats, mice, roaches, fleas, mosquitoes, and all kinds of vermin. It is, for this reason, particularly suited for fumigating cellars, vaults, stables, outhouses, and similar places which are infected with vermin. Formaldehyde, which is such a powerful germ killer, is not poisonous to animal life, and in the strongest concentration of the gas has no effect on roaches, bugs, etc. Places infected with such diseases as plague, yellow fever, and malaria, which are carried about by different classes of vermin, should therefore be fumigated with sulphur.

Formaldehyde is a gas which is soluble in water to the extent of 40%, forming a solution known as formalin. It also occurs in the form of a powder and is then called paraformaldehyde. Whether obtained in the form of a liquid or solid, some means must be resorted to for the liberation of the gas. A great number of devices have been placed on the market for this purpose, some of which require expensive apparatus, while others are comparatively simple. In formaldehyde candles, of which there are many different kinds, the solid formaldehyde is almost always used, and the gas is set free, in most cases, by the heat of a burning paraffin candle. Repeated experiments by bacteriologists have shown that under ordinary conditions at least 2 oz. of solid formaldehyde are required to properly fumigate a space of 1000 cu. ft. Candles selling for 35c. each usually contain 1 oz. of formaldehyde, and two are required for a room 10 by 12 ft. A second method of fumigating with formaldehyde, and which is considered by many to be the most satisfactory and efficient method of fumigation known, consists in setting free the gas from formalin, the 40% solution of formaldehyde in water, by means of potassium permanganate. When using this method 1 lb. of formalin should be taken for each 1000 cu. ft. of space. This is placed in a metal pail of about 3 gal. capacity, which in turn is placed in a pan to guard against any possibility of the material boiling over upon the floor. One-half to three-quarters of a pound of potassum permanganate, in the form of crystals, is then added. In a short time a violent action will take place and the gas will be evolved with great rapidity.

A third method which is quite often used in setting free fodmaldehyde consists in heating the solution in a shallow metal pan on a stove, or over an alcohol lamp. When this is done properly, the method is as satisfactory as any other, and when the means for heating is available, it is more economical than either of the other methods referred to. Whatever method is used in fumigating, the same care should be taken to close all doors, windows, fireplaces, keyholes, and other openings as tightly as possible by stuffing with cloth or pasting over with paper, as otherwise the fumes will escape, particularly on a windy day, before the proper concentration of gas is reached. All articles should be spread out as much as possible or hung up on clotheslines in the middle of the room; window shades should be unrolled; cupboards and drawers should be opened; and mattresses should be so placed that both sides are exposed. Formaldehyde has considerable power of penetration, so that when the fumigation is carried out in the way recommended above, it is not usually necessary to open either mattresses or upholstered furniture, but when articles of this kind are to be fumigated, special care must be taken to make the room tight. The time that a room should remain closed while being fumigated is variously recommended as from six to twenty-four hours, although it is very probable that most of the organisms on exposed surfaces are killed during the first hour, if they are destroyed at all. The longer exposures are recommended so as to permit of ample time for the gas to penetrate into the interior of bedding and other articles requiring more than surface disinfection.

The principal disadvantages in the use of formaldehyde are that the gas has little value as a disinfectant when the temperature of the room is below 60°F., and that, in common with the fumes of sulphur, it is not effective if the air is dry, nor unless a sufficient concentration be maintained for a sufficient length of time. Its advantages are that when used properly it is the most efficient germicide known for disinfecting closed rooms and apartments; it is not poisonous or dangerous to work with; and it is not injurious to delicate fabrics, paints, or metals. In this respect it is practically the only disinfecting agent which may be used in the living apartments without danger of injury to objects of art or value.

A number of powerful disinfectants are not volatile and cannot be used for fumigating purposes, but are valuable for disinfecting solid substances which have been particularly exposed to infection. The most important of these are bichloride of mercury, carbolic acid, cresol, formalin, and chloride of lime, to name but a few.

Bichloride of mercury, or corrosive sublimate, is the most powerful disinfectant known. A single application of a solution containing one part of corrosive sublimate in 500 parts of water is sufficient to destroy the most resistant organisms in a few minutes. A solution of one-half this strength is the one most commonly used. It is especially suited for washing floors and articles of furniture, such as chairs and beds. This is often done as an additional safeguard even when the articles have already been fumigated. Corrosive sublimate tablets, so largely used for general purposes, contain about 50% of ammonium chloride, which renders them more readily soluble. The principal disadvantages in the use of corrosive sublimate are that it is a dangerous poison; it acts injuriously upon materials made of metals; and its power is destroyed by albuminous matter, so that it cannot be used for the disinfection of excreta or sputum.

Carbolic acid is very generally used as an antiseptic. A 5% solution of the crystallized acid in water acts as a disinfectant and is of wide application. A solution of this strength does not destroy metals or fabrics. Whenever possible, garments or implements to be thoroughly disinfected should remain in the 5% solution for about an hour, if cold, but when heated, a much shorter time will suffice.

Cresol, sometimes called crude carbolic acid, is derived from coal tar. It contains little or no carbolic acid, but consists of a mixture of three closely related compounds, all of which are superior to carbolic acid as disinfectants. A 2% solution of cresol is regarded as being a more efficient disinfectant than a 5% solution of carbolic acid, and is considerably cheaper. Like the latter, it does not destroy metals or fabrics and is applied in the same way. Many preparations have been placed on the market containing varying amounts of cresol. Some of the most efficient of these are known in the trade as creolin, lysol, and kreso. Directions are given on the labels for their use not only in washing woodwork, floors, and utensils, but also in disinfecting garbage, sputum, and excreta. They are also used to a large extent as antiseptics on cuts and wounds. As is well known, but not always practised, the disinfection of sputum is of particular importance in the case of consumptives. For this the cresol preparations are well suited. Bacteria are not able to rise from a moist surface, and only get into the air when in a dry state, hence the advisability of the use of sputum cups containing a liquid disinfectant.

Formalin is not only valuable in fumigating, but a solution of it in water may also be used for any of the purposes for which carbolic acid or cresol is recommended. A 5% solution of formalin is generally regarded as superior to carbolic acid of the same strength as a general disinfectant, but it is not commonly used as an antiseptic.

Chloride of lime has long been used for treating foul smelling cesspools and similar places. It is a powerful deodorant, and when properly mixed with the material it is intended to disinfect, it destroys not only the odor, but also the bacteria which give rise to it. Its cheapness makes it particularly suited for this purpose. As a general disinfectant, however, chloride of lime has no advantages over carbolic acid, cresol, or formalin, and has the disadvantages that it is destructive to metals and fabrics, and that it loses its strength on being exposed to the air.

The application of heat is the most reliable as well as the most economical of all methods of disinfection. It is for this reason that refuse, garbage, and all articles of little or no value should be destroyed by burning. It is not at all necessary, however, that articles should be burned in order to insure absolute destruction of any infection which they might contain, for it fortunately happens that germs of all kinds in washable articles may be completely destroyed with certainty by simply boiling in water. The germs of most of the common diseases, as diphtheria, cholera, typhoid fever, pneumonia, and tuberculosis, are instantly killed by boiling water, but linens and all articles of clothing which are disinfected in this way should be boiled for fifteen minutes or so in order to insure that all air spaces in the materials are heated to the temperature of the water. If it is desired to take extra precautions, a small amount of formalin, or one of the cresol preparations already referred to, may be added to the boiling water. It may be mentioned in this connection that the effectiveness of the chemical disinfectants when used for the purpose to which they are suited, is greatly increased by using the solution while hot.

Some bacteria, as for example those which produce blood poisoning, and which give rise to such diseases as anthrax and lockjaw, form what is called spores, and when in this state are so much more resistant that continued boiling for two hours, or even more, is necessary to destroy them. Steam, particularly when under pressure, is much quicker in its action than boiling water, and is the most valuable disinfecting agent we possess. Various appliances for disinfecting in this way have been devised and are used in all hospitals, quarantine stations, and other places where a great deal of disinfecting has to be done.

Under a pressure of 20 lb. to the square inch, steam has a temperature of 248°F., and will then destroy all living organisms in a few minutes. A substance so treated is said to be sterilized. Disinfection implies the destruction of all disease-producing germs without necessarily destroying all of the non-pathogenic bacteria which are so beneficial and so widespread in nature. A body which is sterilized is necessarily disinfected, but disinfecting processes do not always cause sterilization.

Disinfection with steam is particularly suited, with some exceptions, for bedding, clothing, and fabrics of all kinds. Among the articles which are injured in this way may be mentioned leather and rubber goods, furs, and skins of all kinds. Fumigating with formaldehyde is the best way for treating these. The disease germs which are most likely to occur in milk, or drinking water, are all of the non-spore bearing kind, and are therefore very easily gotten rid of by simply heating to boiling. Many are even killed when maintained for a short time at a temperature considerably below the boiling point. Milk heated in this way is said to be pasteurized.

Light is the great natural disinfectant. None of the pathogenic bacteria are able to develop in sunlight, or even ordinary daylight, but thrive best in dark damp places. It is for this reason that well-lighted rooms are so frequently and wisely recommended. The time required for light to cause the death of any particular class of bacteria cannot be stated definitely, as this depends upon the intensity of the light, and the thickness of the stratum containing them. It is for this reason that the time required for sunlight to kill the germs of tuberculosis, which are more resistant to disinfectants in general than the germs of most of the other common diseases, is variously stated to be from a few minutes to several days.

THE Province of Batum, Russia, is rich in all kinds of mineral wealth, although little advantage has yet been taken of its resources. Coal of good quality is found within a short distance of the sea, and antimony and copper in the mountains. The mining industry has been developed slowly because of the lack of transportation facilities and the high prices demanded by the owners of promising locations. A company organized in 1900 and financed by American and English capitalists for the development of copper properties near Batum is perhaps the most important enterprise of its kind in the country. Over $8,000,000 is said to be invested in this company's plant, which has now reached a stage where it is able to pay working expenses and a small profit. The present output is 500 tons per day, but the company intends ultimately to increase its capacity to 1500 or 2000 tons per day. The output is all sold in Russia, where it commands a good price, as the duty on copper imported into Russia is $2.575 per 36.1 lb. The development of this plant is largely in the hands of Americans.

DURING 1910, 15,868 oz. of gold, valued at $307,929, was exported from the Federated Malay States, against 14,864.61 oz. in 1909. Exports of wolfram ore reached $26,623.

The Rogers Concrete Drop-Shaft, Iron River, Michigan

By P. B. McDonald

The Rogers concrete drop-shaft recently sunk at Iron River, Michigan, by the Foundation Company of New York presents several interesting features. It was put down through 140 ft. of shifting overburden on the edge of a swamp, and was sealed to the solid rock without having pumped any water; the water was held back by compressed air in which 50 'sand hogs' did the work of excavation. Just before reaching hard rock, several feet of brecciated rock was found which was not firm enough to seal to, and which had to be removed by expensive labor; this and the fact that it dipped at an angle of 40°, considerably complicated what would otherwise have been a relatively expeditious job. Also, the shaft got out of plumb during sinking, and it was not possible to entirely throw it back into line, so that after the air-pressure was removed one wall had to be chipped an amount varying from 18 inches down.

SURFACE EQUIPMENT, ROGERS CONCRETE DROP-SHAFT.

Steel dividers and guides were put in, making two skipways, a cage-way, and a compartment for pipes, ladders, and a counterweight; the steelwork was supported by brackets fastened to the concrete by bolts.

The sinking of concrete drop-shafts, using compressed air for holding back water and quicksand, was introduced by the Cleveland-Cliffs Iron Co., some four years ago, for several shafts on the Swanzy range south of Negaunee. Attention had been attracted to the process by the success attained by its use in bridge-pier and tunnel work. The method has since been utilized a number of times, both on the Michigan and Minnesota ranges, and its adoption has followed the growing tendency toward exploration of deep, drift-covered deposits by churn and diamond-drilling. Orebodies discovered under heavy overburden by drilling, demand permanent, water-tight shafts for hoisting purposes, and the recent impetus given to diamond-drilling has encouraged the practice of sinking concrete shafts.

The Munro Iron Mining Co. had proved a large orebody by diamond-drilling at the Rogers mine, four miles east of Iron River, and it was desired to sink a shaft in the foot-wall through 140 ft. of glacial gravel, sand, quicksand, and boulders. None of the operating mines of the district are within three miles of the site chosen, so that the overburden gave promise of containing considerable water, especially as a swamp overlies a portion of the orebody.

A timber shaft might have been attempted, but it was known that a mine nearby had been trying to put down a timber shaft for over a year and was having a difficult time. Also, when finished, a timber shaft would let in a large quantity of water, and might give trouble in keeping plumb. Thus the Maas timber shaft on the Marquette range got out of line so badly, and let in so much water, that after several years' use it was filled with sand, and a large concrete shaft sunk around it. Teal lake, not far distant, from which the city of Negaunee obtains its water-supply, had begun to lower materially, so that it was thought the lake was draining into the Maas mine; since the concrete shaft was finished the level of the lake has risen. It is to be understood that it is the thick overburden, with its tendency to shift and conduct large quantities of water, that presents the more difficult part of sinking and maintaining shafts in the Lake Superior region; that portion of a shaft in the solid rock makes relatively easy sinking as compared to the work in wet soil where the excavation is constantly getting out of plumb, and water and quicksand come in in such quantity as at times to force the abandonment of the work. For this reason a concrete shaft is very satisfactory, if the orebody warrants the initial cost, for it is practically water-tight. The Rogers shaft cost approximately $500 per foot; a timber shaft might have been cheaper, or it might have cost more.

The Rogers shaft was started about the middle of February and was sealed to rock about the middle of July. The total time taken was five months; three months were spent on the first 125 ft., during which no compressed air was used, and two months on the last 15 ft. with compressed air at a pressure of from 38 to 45 ft. per square inch as the sinking progressed deeper. The first stage of the work, with no compressed air, went along very rapidly, and consisted simply of dredging dirt with a clam-shell and derrick from the interior of the shaft, so that the concrete casing sank by its own weight, more concrete being added at the surface in 5-ft. sections as needed. During these three months the shaft was kept full of water (to the level of ground-water, about 30 ft. from the surface) which helped wash the dirt from under the cutting edge of the casing, so that the clam-shells could work to better advantage. The bottom or 'cutting' edge of the shaft was pointed and encased in a steel plate for better forcing its way through the overburden. The weight of the heavy concrete walls was sufficient to drive the shaft down as the earth was dredged out from the interior. Vertical and horizontal reinforcements were used in the concrete, both of 1-in. steel, and placed near the outside and inside edges, about 18 in. apart.

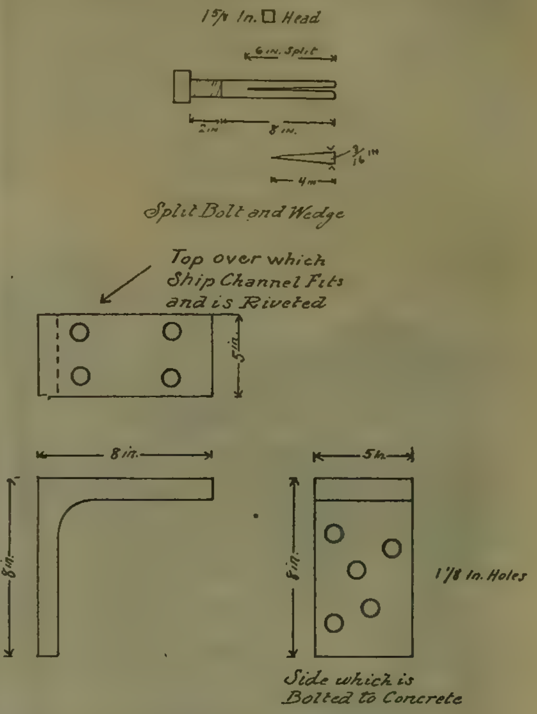
CROSS-SECTION OF SHAFT. DIVIDER SHOWN ABOVE.

The second stage of the work, with compressed-air pressure, held in the shaft by a 6-ft. timber and concrete deck placed across the opening, was made necessary because boulders and hardpan were encountered, requiring men to work with pick and shovel under the cutting edge. The deck was set in notches left in the concrete, and the men and earth were 'locked' in and out through a cylindrical steel chamber placed over a hole cut in the deck. The lock was provided with two doors, one opening into the interior of the shaft where the pressure was, and the other opening into the atmosphere; both doors were, of course, never open at the same time. It was necessary for the men to spend several minutes in the steel chamber in coming out and going in, during which the air was let in or out very gradually, in order to accustom themselves to the difference in pressure, and there was always danger of the occurrence of air bubbles in the blood, causing a painful form of paralysis known as 'the bends.' Consequently there is some danger in connection with working under pressure, and men used to the work had to be brought in, about half of whom were negroes. Each man worked two 40-minute shifts per 24 hr. and received $4; the consumption of energy from 40 minutes in 40 pounds of air is about the same as from an ordinary half-day's work, and no one with a weak heart is allowed to undergo the pressure.



DETAILS OF CONSTRUCTION.

It was estimated that the pressure tending to lift up the timber and concrete deck at 45 lb. per square inch was 700 tons. If through some defect in the apparatus the air-pressure was suddenly lowered, the shaft would immediately have filled with water and sand, and the men probably drowned. For this reason the deck and air-lock were put in with considerable care, and a reliable type, the so-called 'hurricane-inlet' pattern, of air-compressor adopted.

When the rock was reached it was necessary to cut out the soft, oxidized upper layer in order to seal the shaft to hard, compact rock. When this was finally done the Foundation company's contract was finished and the air-pressure was taken off. The shaft had to be delivered by them water-tight, ready for the mining company to begin sinking with rock-drills, and unless the bottom had been properly sealed to firm foundation the shaft would not be water-tight in the bottom. No water had been pumped, so that the level of ground-water of the surrounding country was unchanged, and about 100 ft. head of water was on the shaft. In this respect the method is markedly different from ordinary sinking, in which the level of ground water is lowered by the pumping necessary to enable men to work in the shaft. With the compressed air method, instead of seeking to drain the surrounding country and lower the level of ground water, the water is held back by air of a pressure in pounds per square inch approximately of one-half the number of feet head of water outside. When the casing has been bottomed in solid ground and sinking in rock is commenced, the water can be pumped to better advantage, as it cannot come in so fast. However, the soft rock must be removed from the rock surface while the air is still on, or otherwise the miners will be drowned out by a rush of water when drilling is commenced in rock.

INTERIOR OF SHAFT FROM BELOW.

Putting in the steel dividers after the casing had been sealed to rock was a job requiring careful attention. In the first place, despite the two 6-in. offsets, one wall of the shaft had to be chipped off considerably to make it plumb for guides. It was decided to use 8-in. ship channels for dividers and to support them on steel brackets. To fasten the brackets to the walls, two holes were drilled with an air-hammer drill and the bracket bolted with two bolts, which were driven in on wedges to expand their ends; melted lead was then poured into the holes to make a firm joint.

Gold and Silver Production of Canada

By S. Dushman

The gold production of Canada is mainly derived from the Yukon and British Columbia. The exhaustion of the richer gravels of the Yukon has led to a diminished but much steadier exploitation of the placer deposits. The production from this territory in 1910 was $4,550,000. The future production will probably increase annually, owing to the mining being put on a more stable basis, due to the reduction of costs and the advent of large companies. Large companies are carrying on extensive operations for dredging and hydraulic mining for the purpose of working over the old tailings and large deposits of low-grade gravel.

The gold production of British Columbia was $5,432,000 in 1910, most of it being from auriferous copper pyrite in the Nelson and Rossland districts. It is a question whether electrolytic methods of treating these ores would not be found to be more economical than the present metallurgical methods. In the treatment of the auriferous gravels of the placer deposits it is very likely that some process of electrolytic amalgamation might also be found to yield better results than the ordinary amalgamation methods. The remarks of E. E. Carey are worth while quoting in this connection. "In the near future we may look for a greatly increased production of gold, due to the application of electrochemical methods in mining and milling operations. Were electro-amalgamation and electro-cyanidation today in general use in other mills now in operation, the gross output of gold would be increased 25%. The great increase in the future supply of gold, however, will come from vast low grade deposits which cannot now be mined.

That the gold resources of the Yukon and British Columbia have only been skimmed, as it were, is evident from the fact that the mountain ranges of this territory in which gold deposits have been found so far form the northern extremity of the western or Cordilleran belt, which, extending from South America to Alaska, is recognized as one of the greatest mining regions of the world, noted principally for its wealth in gold, silver, copper, and lead." In both Mexico and the United States this mountain range has yielded about $3,000,000 per mile of its length, and it is only reasonable to expect that Canada, which possesses over 1300 miles of this range, will yield enormous amounts of the precious metals in the future. The resources of placer gold in the Klondike alone have been estimated at $100,000,000. Up to the present probably not one-twentieth of this vast area has been prospected in detail.

About 90% of the silver produced in Canada in 1910 was derived from the rich silver deposits of Cobalt, Ontario, the rest being derived from British Columbia. Since the discovery of the Cobalt deposits, in 1904, the production of Canada has grown rapidly; in 1910 this country produced 32,000,000 oz., or 13.3% of the world's total production.

Fine silver is produced only at Trail, B. C. as a by-product in the lead-refining process. In Ontario ores from the Cobalt district are at present being treated at three metallurgical works operated by the following companies: The Canadian Copper Co., at Copper Cliff, Ont.; The Deloro Mining & Reduction Co., at Deloro, Ont.; The Coniagas Reduction Co., at Thorold, Ont. Silver bullion of fineness varying from 850 to 998.2 is produced at the works, other products being white arsenic, and in the case of the Coniagas plant, nickel and cobalt oxides. In each case residues carrying silver, arsenic, cobalt, and nickel are either shipped to the United States or held in reserve for further refining. In 1909 about 52% of the total silver production was recovered in Canada as fine metal or bullion.

The ores of the Cobalt district are extremely complex, and the problem of treating these ores economically is still awaiting a solution. Under present conditions one of the pressing needs for the further promoting of mining and metallurgical activity in northern Ontario is the devising of suitable methods for the treatment of the Cobalt silver ores. Only about 30% of the ore shipped from Cobalt in 1909 was treated in metallurgical works in Canada, most of this being high-grade silver ores, and the rest was shipped to a number of large companies operating in the United States. With respect to the content of nickel, cobalt, and arsenic in the ores, the mining companies are paid only for a small portion of the cobalt content, and nothing for the nickel and arsenic; in fact, in certain cases, the latter two are penalized.

In the solution of these problems there is undoubtedly a field for the electrochemist and electrometallurgist. Not only is there an abundance of mineral wealth in the Cobalt region itself, but even in the districts farther north, deposits of the most varied nature have been unearthed. Iron, copper, molybdenum, silver, gold, and even small diamonds have been discovered in the lone land south of Hudson's Bay. The whole of the Temiskaming region appears to be a vast mineral deposit where the richest ores and minerals of the earth have been thrown together in the past ages, in a most haphazard and extraordinary manner, so that one knows not what to expect in the future. Added to this is the fact that there are abundant waterfalls throughout the whole region. The facilities for transportation are being increased as fast as the country demands them; the government of Ontario has constructed a direct line to open up the agricultural and mining districts of the north of the province and is operating it by a commission. All these considerations serve to emphasize the fact that the hopes which are entertained for the electrochemical future of northern Ontario are not without some warrant.—*Applied Science.*

Manganese Mining in British India

By Herbert A. Carter

Manganese ore, as is fairly well known, is principally used in steel metallurgy, and the manganese market is regulated by the requirements of the iron and steel trades, which consume at least nine-tenths of the world's output of the ore. A period of great prosperity in the steel industry (1905-7) led to a much larger demand for manganese ore, just at a period when the Russian output, the most important source of supply, was reduced by the political disturbances in that country. Prices, as a result, rose quickly, which developed prospecting in India and elsewhere, and led to the discovery and working of new deposits of the ore, together with a much larger output from the mines then in existence.

Manganese mining commenced in British India in 1892, and the yearly output from the mines since that date has steadily increased, with the exception of slight fallings off in 1898, 1902, and 1904, to a maximum of 916,770 metric tons in 1907, so that it is possible India produces more manganese ore at present than Russia. The production of the United States, though large, is chiefly made up of manganiferous iron ores. Production in India up to 1900 was confined to the Vizagapatam district, in the Madras presidency, but in that year a beginning was made in the Central Provinces, however, and since 1902 the mines in the Central Provinces have provided the bulk of the Indian output. The industry opened out in the State of Ihabua, central India, in 1903, in the Sandur State, Madras, and in the Belgaum district, Bombay, in 1905, in the Pauch Wahals district, Bombay, in Mysore State, the Portuguese territory of Goa, and the Singbham district, Bengal, in 1906; in the Las Bela State, Beluchistan, in 1907, and in the Gahgpur State, Bengal, in 1908. Between the years 1905 and 1907 the manganese production of India rose from 250,000 to a maximum of 916,770 metric tons. Prices for first-grade ore rose from a minimum of 8¾d. per unit at the end of 1904, to 16 and 18d. in the early part of 1907, but in February 1908 quickly fell to 10d., and have since changed but little from 9½d. This fall in prices was due to the financial crisis of 1907, which lessened steel production in the autumn of that year; the great demand then for the ore was curtailed, and large stocks of ore, which for the time being were unsalable, helped also to depress the market. Manganese mining in India during 1908 was limited to those mines which had made contracts during the time prices were high, and although the steel trade became good again in 1909, the demand continues below the available supply.

Manganese ores are to be found in many widely separated districts of India, and almost all the deposits which are of economic importance are found in Archean rocks. Some deposits of a superficial character are found in laterite. Manganese ore was at one time made use of in the manufacture of chlorine and bleaching powder from pyrolusite. For this the ore must contain at least 70% of manganese peroxide, and small quantities of pyrolusite are also employed for various lesser chemical and manufacturing purposes. By manganese dioxide is meant the commercial powder.

The manganese ore deposits in India can be divided into three divisions in accordance with their origin. The first are those derived from a distinct series of igneous Archean rocks, rich in manganese, by processes of decomposition of a secondary nature, and like replacement, acting within the zone of weathering. This division is represented by the deposits formed in the Vizagapatam district. Second, those derived from manganese, the source of which is very probably the same series of igneous manganiferous rocks referred to, already precipitated from solution as hydrated oxide contemporaneously with the decomposition of the enclosing strata which now compose the subdivision of the Archean group known as the 'Dharwars'. After the consolidation of the series of sediments, the rocks were subjected to more or less severe metamorphism, with the result that an important change in the character of the ore-bands, as a rule, occurred, the manganese oxide combining with the intermixed or interstratified clay, or sand, commonly present, with the formation of manganiferous silicates (especially spessartite, a manganese-alumina garnet, and rhodonite). By later chemical alteration, thought to have taken place at considerable depth before the action of denudation brought the series within the zone of weathering, manganese ores (oxides) were largely reformed, but recent outcrop oxidation has also contributed in most cases to the surface enrichment of the orebodies. This division comprises all the important Indian deposits, including those of the Central Provinces which do not come under the headings of the first or third divisions. Third, those derived from manganese compounds disseminated in small proportions throughout the Dharwar series, as a rule, and concentrated by superficial replacement, and segregation of the manganese in the decomposed outcrops, and in masses of laterite, formed on the outcrops of the underlying rocks, usually Dharwars. This division includes the deposits of Sandur, Mysore, Goa, and other localities. In a limited number of instances the manganese is most likely of composite origin, being in part derived from original sedimentary deposits and partly enriched by superficial replacement by means of percolating waters carrying manganese in solution.

There is no difference in the character and mode of occurrence of the deposits divided into the three genetic divisions. The first class is of irregular shape and size, strewn in soft decomposed rock, and as a rule outcropping on level ground. The second class forms regular beds interstratified in metamorphic rocks, usually schists and quartzite with a steep dip, and very frequently forming a background for ridges which stand out above the plain; though this is not the case when the enclosed strata are mostly soft schists. The third class, as a rule, forms the crest of small hills, or is found irregularly as segregations, and concretions, in laterite and subsoil.

As to the resources of India in manganese ore, many millions of tons of oxide exist obtainable by the present open-cut methods, but a general lack of development work in depth prevents any exact estimate being made. Though enormous, the amount is not inexhaustible, and within the next decade or two those best fitted to speak on the subject consider it will be necessary to make use of much second-class ore, crushing and concentrating by mechanical means, and also to consider the adoption of underground work in the larger and more persistent types of deposits. The depths to which salable oxidized ore extends in these deposits is, however, as yet unproved, but it could be ascertained by the aid of diamond-drilling. It is, in fact, possible that a general exhaustion of the oxidized ores may ultimately force metallurgists to utilize the unoxidized silicate ores, carrying 30 to 40% manganese, but this is not a matter which need disturb the present generation.

The deposits in India are worked by open-cut methods with coolie labor, usually under a contract. The ore is pried out with crowbars, or drilled and blasted, a certain amount of deadwork being necessary in the country rock which encloses the deposit. In boulder ore, concretionary ore in clay, and subsoil the material is simply excavated or turned over, and the lumps of ore picked out by hand. The ore quarried is broken where necessary to a convenient size for handling, and separated from admixed rock, or low-grade mineral, by sorting and cleaning with small hammers. The waste goes to the dump, while the ore is carried away on the heads of women and children, and piled into rectangular heaps which are then measured, and the tonnage calculated from the cubical contents (15 to 20 cu. ft. per ton, according to the specific gravity and mechanical condition of the ore). In some of the large mines situated on hills the transport to the stacking ground is facilitated by the use of aerial rope-ways, and gravity inclines, and chutes are at times used. The total mining costs vary greatly, being as low as Rupees 1 to R1-8-0 per ton in the mines of the Central Provinces, and as high as R6 in some of the Vizagapatam mines, and in some of the small irregular deposits of Goa and Mysore. The royalty payable in British India is 2½% on the selling value of the dressed ore at the mine, and the rate per ton has varied between 1 anna and 4 annas, according to manganese prices. In native States a fixed royalty of 4 or 6 annas per ton is usually charged.

When an analytical chemist is employed at the mines, the stacks of ore are sampled and analyzed separately, in order to control the grade of the ore and to meet the requirements of the contracts on which it is sold. The manganese content must not be let fall to a point which will entitle the buyers to reject the consignment, and for the same reason the injurious impurities (silica and phosphorus) must be kept within the limit allowed. After the measurement and sampling of the stacks, the ore, commonly composed chiefly of a mixture of the manganese minerals, psilomelane and braunite or pyrolusite, is carried to the railway by bullock carts which hold half to three-quarters of a ton, or by light steam tramways in trains of 25 or 30 cars, each holding one to two tons. Carting costs 2 to 4 annas per ton per mile, while the tramway service costs about 6 pice. The ports from which the ore is exported are, in order of importance, Bombay, Vizagapatam, Marmagoa, and Calcutta. With Vizagapatam deposits the railway freight to the port costs about R1-4-0, while the Sandur and Mysore ores pay about R5-12-0, and the Central Provinces ores (via Bombay) R8, and (via Calcutta) R10. At the ports the ore is stacked for shipment; which is usually in consignments of 1000 tons and upward. The charges at the port are R1-4-0 to R1-8-0 per ton, and about the same cost is incurred at the port of destination. The freight to English ports, and ports on the Continent is usually about R12 per ton, and about R13-8-0 in the United States. Central Provinces ore, via Bombay, costs about R27 delivered c.i.f. at English and Continental ports, while Vizagapatam ore costs about R28-8-0. The average cost at which the Indian ores can be placed upon the market will bear favorable comparison with the cost of the Russian and Brazilian ores, and they compete with them. On reaching the ports of destination, the ore is unloaded into railway cars, occasionally into lighters, the weight is determined, and the ore delivered at the works.

Manganese ore is sold on contracts made between the producer and consumer, or an ore-broker who occupies the position of a middleman. The price obtainable varies widely, according to the market rate per unit of manganese. Thus a 50% ore realizes at times when the metal is at 9d. per unit, £1 17s. 6d., or R28-2-0 per ton; the same ore when manganese stood at 16d. per unit, would have realized £3 6s. 8d., or R50 per ton. The permissible amount of silica and phosphorus is arranged for in the contract, as well as the manganese basis on which the ore is to be paid for, with provision for deductions for excess amounts, and the right to refuse ore of above fixed maximum limits. The limit of free silica is generally 8 or 10%, and that of phosphorus 0.10 or 0.12%, though ores with twice this amount of phosphorus meet with a sale at lower prices. They are principally employed in smelting sulphury iron ores. A rejection limit for the manganese is named in addition, and the iron content is paid for in some instances, but not in others. Ore that contains too large a proportion, say above 15%, of fine ore is objected to by purchasers. The composition of the ore, and accordingly the price to be paid for the consignment according to the conditions of the contract, is fixed by an official sample drawn at the port of loading, or of destination, by persons who represent the buyer and seller acting jointly, or by an independent firm of samplers and assayers. In either instance a number of sealed portions of the samples are analyzed on behalf of both parties, and the mean of agreeing results is accepted. The moisture which is found is deducted from the weights, and the analysis, as a rule, reported on the dried sample. The great bulk of the manganese ore marketed is smelted in blast-furnaces for the production of ferro-manganese and spiegeleisen, which typically contain 80 and 20%, respectively, of manganese, the other constituents of importance being iron, carbon, silicon, and phosphorus.

Manganese forms several oxides, the most important of which are manganese oxide, MnO, trimanganese tetroxide, Mn_3O_4, manganese sesquioxide, Mn_2O_3, manganese dioxide, MnO_2, manganese trioxide, MnO_3, and manganese heptoxide, Mn_2O_7. It is difficult to prepare a pure hydrated manganese dioxide owing to the readiness with which it loses oxygen, leaving residues of the type $xMnO\,yMnO_2$. Manganese salts can be detected by the amethyst color they impart to a borax bead, and by the green mass formed when they are fused with a mixture of sodium carbonate and potassium nitrate. Manganese may be estimated quantitatively by precipitation as carbonate, this salt being then converted into the oxide, Mn_3O_4, by ignition, or by precipitation as hydrated dioxide by means of ammonia and bromine water, followed by ignition to Mn_3O_4. The valuation of pyrolusite is generally carried out by means of a distillation with hydrochloric acid, the liberated chlorine passing through a solution of potassium iodide, and the amount of iodide liberated being ascertained by titration with sodium thiosulphate.

Manganese steel is very strong, hard, and extremely ductile; it contains about 12% of manganese and 1.50 of carbon, although the presence of 1.50% of manganese makes steel relatively brittle, and while a further addition at first increases this brittleness, so that steel containing between 4 and 5.5% can be pulverized under the hammer, yet a further increase gives the remarkable result of good ductility, accompanied by hardness, a combination of properties which was not possessed by any other known substance when this remarkable alloy known as manganese steel was discovered. Its ductility, to which it owes its value, is profoundly affected by the rate of cooling. It is used largely for objects which need both hardness and ductility, such as rock-crushing machinery, railway crossings, mine-car wheels, and safes. No process softens manganese steel rapidly, and this very fact that it is unalterably hard has limited its use because of the great difficulty of cutting it to shape, which has in general to be done with emery wheels instead of the usual iron-cutting tools, another defect in its relatively low elastic limit.

In the manufacture of steel the manganese alloy is added at the conclusion of the process, just before the metal is cast into ingot molds. This effects the following: (1) the reduction of the small amounts of iron oxide present in the molten metal; (2) addition of the manganese needed in the finished steel (about ½% on an average); (3) formation of blow-holes minimized, reduction of the sulphur content, and production of a fluid slag.

Some of the carbon needed in the finished steel is contained in the manganese alloy added, while the balance is added as charcoal, or in some other form that is convenient. The quantity of manganese added as alloy averages about 1% of the steel. A special steel which is called manganese steel contains 13% of manganese, as a rule, and is very hard and tough. Other alloys of manganese which are made are silicon-spiegel and manganese-bronze. Manganese bronze is employed for ships' propellors, as it is very tough and strong, and is not liable to corrosion by sea-water. It is composed of copper, manganese, aluminum, and zinc.

Manganese steel is made by Hadfield's Steel Foundry Co., Ltd., Sheffield, England, the Edgar Allen American Manganese Steel Co. of Chicago, and the Taylor Iron & Steel Co., Highbridge, New Jersey. It is specially suitable for certain wearing parts of grinding and elevating, as well as crushing machinery, as its wear-resisting properties are extraordinary. Manganese in small quantities has little influence on the character of the metal. When the quantity of manganese rises to 2.5%, the strength and ductility diminish, and the hardness increases, the influence reaching a maximum with about 6% of manganese. With larger quantities strength and ductility increase. It casts well, the castings being free from blow-holes, and forges well at a moderate temperature, and manganese steels are remarkable by not being susceptible to magnetization.

An Old Treasure Town

By [illegible]

[illegible]

RUINS OF SPANISH SMELTING PLANTS

the lode vein which extends for several miles across the country, and the mine soon became a great producer, yielding almost fabulous amounts of silver; indeed, it is yet on record that during the great bonanza in the eighteenth century [illegible] one million dollars was taken out in less than eight years. Several great plants were built to treat the ore, and are the largest of their kind that I have ever seen. Two of them are still in a fair state of preservation, of one only the foundations remain, while a fourth has entirely disappeared, with the exception of a ruined stone arch thickly overgrown with cactus. I will add that the stones from the last two were carried away by the natives to build the modern town.

These reduction plants merit description, as they are excellent examples of early Spanish architecture in Mexico. They are constructed entirely of stone, and each one covers about ten acres; from without they present the appearance of a great square fort, with one or two massive gateways, and almost no windows in the outer wall. Clearly they were built for defence, as the outer walls are about three feet thick. Within the enclosure all around the wall are [illegible] of buildings, while the central part consists of a great yard or patio, where the ore was treated. There are abundant remains of mercury tanks and ditches, and old [illegible] cut from a single block of stone, while the ruins of a dozen adobe furnaces testify that smelting was also practised there. The long rows of columns and arches which give the great rooms and halls the appearance of a monastery are especially notable. These columns were placed down the centre of the big rooms and were necessary to support the roof, as the rooms were far too wide to be spanned by single beams.

[illegible]

METHOD OF TRANSPORTATION.

the old ruins at night. Some of them firmly declare they have seen the ghostly occupant peering over the wall on stormy nights, and I have no doubt they believe it. Although an unbeliever in ghosts, I tried to get a glimpse of this spook, going into the ruins at night on several occasions and waiting patiently for hours, but he failed to put in an appearance.

When the Mexican Revolution broke out in 1810, the principal owner of the mines resided in Ramos, and was killed there. As he was possessed of considerable wealth, and none of it was ever found after his death, there is a foundation for the story that a great treasure is hidden somewhere in the old ruins. Legend has it that one night shortly before he was killed, the Spaniard and his servants threw all his treasure, in silver bars, down the main shaft of the mine. When the mine was unwatered, all the treasure would be found, it was said; but alas, when the water was removed, no treasure was there. Another tale said that deep underground was a passage between two of the mines, closed with an iron door; near that door would be found the treasure. The door was actually found some years after the reopening of the mines, but no treasure. Perhaps there is still a fortune hidden away somewhere, waiting for the lucky finder, but the possible places of concealment are so numerous that even a systematic search would occupy many months.

But hidden treasure has actually been found in the old town. There was an American miner living in one of the fine old houses there, a house called the *Alto Blanc*, or 'the white house', and one day, probably by accident, he discovered a secret hiding place in the wall, from which he took thirty thousand dollars. Then there was an old Mexican who dreamed three successive nights of finding a treasure in one of the bandit caves near the town, and finally went there and dug in the floor of the cave, where he found a considerable sum of money, this story is also well authenticated. Afterward some of the Americans visited the same cave, but only succeeded in unearthing a few bones and human skulls. When the old town began to revive, after the advent of the Americans, some strange things came to light. A family, having moved into a long-disused house, were sitting at dinner one day when they were startled by a portion of the wall falling in, revealing in a niche in the thick wall, a skeleton standing upright. Who was this unexpected guest? How came he there? These are questions that will never be answered. An eye-witness of this strange occurrence informed me that the skeleton held a paper in its hand, yellow with age and with faded writing on it; but as the family were illiterate people, the skeleton and its unread missive were consigned to rest in the village cemetery. In another old house there was discovered a walled-up closet containing the remains of two skeletons, suggesting some long-forgotten crime.

COCINERA MINE PLANT.

Ramos is in the northwest corner of the State of San Luis Potosi, and about thirty miles east of the city of Zacatecas. It lies on a high plateau, and the nearest mountains are fifteen miles to the west; the country rock is andesite, and nearly all the mines are along a fissure vein which is almost vertical and traverses the country from north to south for about twenty miles; all the mines are near the southern extremity of this vein, and within an area of one square mile.

The Cocinera is the largest mine, and the depth in 1901 was 1200 ft. The Spaniards worked this mine to a depth of 900 ft., when a barren streak about 100 ft. thick was found. The vein matter is a decomposed quartz, impregnated with various copper minerals, the sulphides, chalcocite, bornite, tetrahedrite, chalcopyrite, galena, and blende predominating. The average width of the vein is 15 ft., and the ore occurs in large pockets, sometimes in great masses; the walls are well defined, but the mine is very wet and hot. It is worth noting that the galena in these mines is almost barren of silver, while the blende carries a good quantity. The sorted ore from the Cocinera averaged 5 kg. silver and 14% copper, with from 8 to 10% lead, and 5 to 10% zinc; there is no gold in the entire district. At a depth of 1100 ft. a great body of oxidized ore was found, containing the copper almost entirely as red oxide; in this orebody was found a few pounds of silver-gray mineral, which on analysis gave the formula $AgCu_4S$. Its structure was massive, and under a high-power microscope was shown to be perfectly homogeneous and not a mixture; apparently it was a new variety of stromeyerite. There was also much native silver and copper found in this oxidized vein.

North of the Cocinera is the San Vicente, about 600 ft. deep, which also showed considerable ore on unwatering. When the water was drained away, the walls in some of the levels were found incrusted with a coating of goslarite crystals ($ZnSO_4$.) Also, several old Spanish miners' candles were found in which the tallow had been almost entirely replaced by green copper carbonate, so that the candles crumbled on handling. North of the San Vicente, on the same vein, there are, in a distance of one mile, about twelve other shafts, most of which are either fallen in or full of water. Most noteworthy is the Colorado, a circular shaft of red masonry about 6 ft. in diameter, which is now completely caved in at a depth of a little less than 100 feet.

Three miles north of Ramos is a large deposit of copper carbonates and silicates on a vein parallel to the great vein; the ore averaging 2 to 3% copper and very little silver. A few miles northeast of the town is a low range of hills of red volcanic rocks, tufa or scoria, which are late intrusives. The entire district contains numerous fissures of black basalt, and is covered with a calcareous deposit called *caliche*, varying in thickness from a few inches to several feet; this deposit is apparently of earlier formation than the red dikes. About eight miles east of Ramos, a great dike of white quartz, projecting several feet, traverses the country for a long distance north to south; the quartz averages about 2 gm. silver per ton. In the Santiago mountains, 15 miles west of Ramos, are several deposits of low-grade copper carbonates and silicates averaging from 3 to 5% copper, with about 170 gm. silver. There are also in the Ramos district many tons of copper slag and tailing from the *patio* process of the old Spanish days; much of this tailing averages from 2 to 5% copper and 250 to 500 gm. silver.

Economy in Power Transmission

By C. R. Trowbridge

The line-shaft of a system of machinery has been termed the highway for power, and the comparison is apt, for in many ways it bears an analogy to the roadbed of a railway. The ballast of a railroad may be compared to the balance of the rotating members upon a line-shaft; every pulley should be in perfect balance, and, so far as possible, the pull of belts in opposite directions be equalized. Not only as regards balance, but also in connection with support and alignment, may the line-shaft be compared to the railroad line. It must be firmly supported, and thus the hangers and bearings come into play, and its alignment must be correct and self-correcting, otherwise harmful resistances will multiply rapidly, and efficiency fall off accordingly. It should never be forgotten that the final efficiency of any system, such as that of a line-shaft and distribution, consists of the continued product of the several detailed efficiencies, so that any small falling off in the various elements will produce a much greater influence upon the whole. This means that the closest vigilance is necessary upon all details—watchfulness in the shop, in the erection, and in the continual operation. It does not mean, however, that the transmission should be a continual source of anxiety and trouble to the superintendent of motive power, for if the mechanism has been properly designed and erected it will take care of all these questions automatically. If the hangers are of the real ball-and-socket construction they will place the bearings themselves in parallel with the shaft at all times; if the adjustments may be made in all directions, the shafting can be placed in perfect alignment and kept there; while if the various portions are provided with independent friction-clutch connections, every opportunity is given for control over the whole system or any of its parts. Efficiency in manufacture means efficiency in operation, but there is yet a further kind of efficiency—that completeness which is always ready for any emergency. When it is understood that every detail of a power transmission system is kept in stock, it will be realized that there is an efficiency of the highest character, an efficiency which permits a minimum of loss in time in the case of accidents, changes, or extensions.

Determination of Copper by a Modification of the Iodide Method

By E. C. Kendall

[*]The modification of the iodide method as described in this paper consists in the destruction of the nitrous acid without boiling. This is accomplished by the addition of a small amount of sodium hypochlorite. The addition of sodium hypochlorite to a nitric acid solution produces hypochlorous acid. The interaction of hypochlorous acid and nitrous acid results in the oxidation of the nitrous acid and the formation of hydrochloric acid, and the reaction between hypochlorous and hydrochloric acid results in the destruction of the hypochlorous acid and the formation of free chlorine and water. As the solution of sodium hypochlorite contains small amounts of chlorides, hydrochloric acid will always be present when the solution is acidified, thus insuring the destruction of the hypochlorous acid and the formation of free chlorine. The effect of adding sodium hypochlorite to the solution is the complete destruction of the nitrous acid and the formation of free chlorine.

To remove the free chlorine in solution some compound must be added which will take up the chlorine, but will not affect subsequent operations. Such a compound is found in phenol. Under the conditions of the determination, phenol will add chlorine directly to the benzene ring, but is not affected by iodine or any of the other compounds in the solution. Chlorophenol not being ionized removes all traces of free chlorine. This modification of the method greatly reduces the time and attention required for a determination, and, in addition, the copper solution is prepared in such a way that iodine can be liberated by copper alone.

In the determination, the copper, copper oxide, or sulphide is dissolved in nitric acid. After the addition of the sodium hypochlorite and phenol, which requires but a moment, the solution is made slightly alkaline with sodium hydroxide, and is then made acid with acetic acid, when the solution is ready for titration. Potassium iodide and starch are added, and the titration is made to the disappearance of the starch iodide color. There is never any fear of the blue color 'flashing back', and the solutions will remain colorless indefinitely after the titration. As the ionization constant for acetic acid is too low to allow nitrates to liberate iodine, the amount of nitric acid in solution is immaterial. Even 20 c.c. of concentrated nitric acid will not affect the titration. However, too great an acidity is to be avoided, as nitrophenol will be formed. The presence of nitrophenol prevents the determination of copper, but there is no danger of its formation even in the presence of a large amount of acid, if the solution is neutralized soon after the addition of the phenol. If a large amount of nitric acid is used to dissolve the copper, it should therefore be partly neutralized before addition of the phenol.

As chlorine easily oxidizes phenol to compounds which prevent the determination of copper, it is essential that all of the phenol be added quickly to the solution. Under these conditions the chlorine adds directly to the benzene ring, but if the phenol is added drop by drop the chlorine will oxidize it, producing colored compounds in solution. In order to add the phenol quickly enough to the solution it may be poured in from a beaker, or, a more convenient way, from a pipette from which the tip has been removed, so that the delivery is from an opening which is of the same bore as the rest of the tube. By forcing the phenol out of such a pipette with the breath the entire volume is added very quickly and at the same time the phenol is well mixed with the contents of the flask. After addition of the phenol the chlorine gas which is in the flask above the liquid is removed by blowing it out with the breath, and the sides of the flask are washed with a jet of water from a wash bottle. There should be no odor of chlorine just before the solution is made alkaline.

It should be remembered that the end point of the titration is not pure white. Cuprous iodide has a cream color, and when a large amount of copper is present the cuprous iodide gives a decided tint to the solution. When the end point is nearly reached, a drop of the thiosulphate is allowed to fall into the centre of the flask. If a change of color occurs the solution is given a slight rotary motion, and after the solution is again quiet, another drop of the thiosulphate is added. The 'spot test' is easily recognized and gives a very accurate end point. The speed of reaction of the copper with potassium iodide varies with the volume. In a small volume the action is rapid, and all of the iodine is liberated at once, but in a large volume an appreciable time may be required for all of the copper to react. This is especially noticeable when a small amount of copper is present. A high concentration of potassium iodide greatly assists the liberation of the iodine. Accurate results cannot be obtained unless at least 3 gm. of potassium iodide are added, irrespective of the amount of copper present, up to 500 mg. of copper.

If the copper to be determined is present as metallic copper, 200 to 300 mg. is placed in a 300-c.c. flask and dissolved in 5 to 10 c.c. of 50% nitric acid. If the copper is present as cuprous oxide, it is filtered on a Gooch crucible through asbestos. The cuprous oxide is then dissolved through the Gooch crucible with 10 to 15 c.c. of 30% nitric acid into a 300-c.c. Erlenmeyer flask. If the copper is in the form of sulphide, it is filtered on a Gooch crucible which has a layer of asbestos ⅛ in. thick. The crucible is then placed in a small beaker of 50-c.c. capacity, and 10 c.c. of 50% nitric acid is added. The beaker is placed on a hot plate, and the nitric acid allowed to boil until all the black sulphide has gone into solution. The crucible is then washed off, and the solution transferred to a 300-c.c. Erlenmeyer flask. The presence of the asbestos in the solution does not interfere with the titration of the copper. If the copper to be determined is already in solution as sulphate, chloride, or other salt, sufficient solution is taken to give 100 to 300 mg. of copper.

Having obtained the copper in solution, preferably in a 300-c.c. Erlenmeyer flask, the volume being between 50 and 60 c.c., the acidity is adjusted to equal 4 to 5 c.c. of concentrated nitric acid. A greater volume or acidity is to be avoided. The temperature should not be above 25°. Five cubic centimetres of the hypochlorite solution is now added to the copper solution, which is well mixed with a rotary motion. As soon as the color of the copper solution changes from a clear blue to a greenish tint, sufficient hypochlorite has been added. Another indication of a sufficient amount of hypochlorite is the liberation of chlorine. For weights of copper up to 200 mg., 2 to 3 c.c. of the hypochlorite is sufficient. For larger amounts of copper, more hypochlorite may be needed, but 5 c.c. will be sufficient for any amount of copper which would be determined by this method. The reactions between the hypochlorous and nitrous acid require an appreciable time, and the best results are obtained by allowing the solution to stand about 2 minutes before the addition of the phenol. This, however, is not essential. Ten cubic centimetres of the phenol solution is now added as quickly as possible, by blowing the solution from a pipette from which the tip has been removed. The chlorine gas which remains in the flask above the liquid is removed by blowing into the flask, and the sides are washed down with a jet of water. If the solution is allowed to stand at this point, nitrophenol will slowly form. Sodium hydroxide is therefore added until a very slight precipitate is obtained. The solution is now made acid with acetic acid; only a few drops should be required to dissolve the precipitate; 10 c.c. of the potassium iodide is added and the titration made with the standardized thiosulphate. If great accuracy is required, the titration is finished with a weak solution of thiosulphate.

---

[*] Abstract from the *Journal* of the American Chemical Soc., December 1911.

The blister-copper production from Pennsylvania in 1910 was 740,626 lb., as compared with 994,089 lb. in 1909. The output was from the iron mines of Lebanon county. These ores carry a small amount of pyrite and chalcopyrite.

Making Laboratory Cyanide Tests

By George A. James

It has been my object to devise an apparatus for laboratory cyanide tests that will duplicate the conditions of actual practice, and that will handle quantities large enough to obtain accurate results, in checking solutions and tailing after treatment. I have used such an apparatus over a year with gratifying results.

The accompanying sketch shows the apparatus now in use. A large glass tube, *A*, 60 in. long and not less than 1¼ in. internal diameter (1½ in. is preferable) at the lower end, is covered with a filter medium of cloth or canvas, which is held in place by a tight fitting ring of metal or by rubber bands. The measuring flask, *B*, should have a neck small enough to enter the glass tube and a capacity of 2000 c.c. This is fitted with a cork, through which two small tubes enter the neck of the flask. One protrudes about an inch and the other must be at least three inches longer. The purpose of this arrangement is to provide a self-regulating feed to the percolation tube, *A*, and to prevent the contamination of the solution by the laboratory gases.

As the shorter tube provides the only inlet for air, its length regulates the height of the liquid column in *A*. Its length can be regulated as desired, but the two tubes must differ in length sufficiently to assure a flow of solution. A difference of three inches is sufficient. *D* is a funnel with an overflow tube covered with a small piece of rubber tubing, which may be pressed into the neck of the funnel, thus retaining sufficient solution for tests. This always represents the last liquid received, and can be allowed to enter the solution reservoir by releasing from the neck of the funnel, or it can be withdrawn if so desired. These large tubes are very susceptible to changes of temperature and should be protected. This can be done by pasting thick paper over them, allowing enough glass exposed for observation.

Before using the tube for experiment, it should be graduated. As the tubes are not always of regular diameter, it is well to mark them permanently at the points reached by successive additions of not more than 500 c.c. of water. This provides a simple method for determining the specific gravity of ore charges, when using the tubes for experiments. In using the tubes the ore charge is introduced, preferably with a funnel, from the top. The feed regulator, *B*, is then inverted in the neck of the tube, and no further attention is required. It is well to bend the point of the discharge tube of the supply flask so that the liquid will not drop directly on top of the ore charge, but against the wall of the tube *A*.

After introducing the ore charge and solution as described, the time is noted. For this purpose an experiment card is provided for each apparatus, which it is best to hang conveniently at hand. This card should be provided with columns in which are entered all the amounts of liquid removed for tests, the total content of solution in chemicals, and the total content of the ore charge in gold and silver. I use 1 kg. of ore in most tests, and estimate the total milligrams of gold and silver contained. As soon as the solution is exhausted from the solution-reservoir, the speed of percolation can be noted. This can be taken as correct for similar depth of ore-beds, no matter what diameter the beds may have, and can be safely rendered as the speed of percolation for similar charges on a large scale. It is important to keep track of this detail during the time of the experiment. When the entire solution has passed through the ore charge, the amount recovered is measured (with allowance made for solution appropriated for tests), and the difference from the original amount charged to what is held by the ore. If wash water has been used, the amount held by the ore charge must be known, and its effect considered in increasing the quantity of solution, with its bearing on the cyanide strength in tests, also in precipitation for gold and silver extraction.

It is my custom to precipitate the gold and silver after the passage of each total quantity used, with a weighed amount of zinc dust, remove the precipitate by filtration, and reduce in the assay furnace, thus obtaining the actual metal leached, and introducing the effect of zinc found in solutions used in practice. These incomplete recoveries are compared to the original amount in the ore charge, their proportion to the remaining metal in the tube noted, and furnish an accurate comparison of the progress of the experiment. After a few tests a factor is found that will make them accurate enough to determine the progress of the work and indicate the point desired. The assays of the tailing remaining in the tube should be expected to check closely.

Ring or Rubber Bands
Filter Cloth

LABORATORY CYANIDE APPARATUS.

Where it is desired, a portion of ore charge can be removed by a sampling device. I use for this purpose a glass tube, attached to a rubber tube sufficiently long to permit its entrance from the top of the percolation tube. This is allowed to rest on top of the ore charge. By suction it will enter into and draw up the pulp. This can be withdrawn, with its contents, by pressing the rubber tube to prevent the entrance of air. By slipping a heavy rubber band over the filter-cloth of the percolation tube, to form an air-tight connection, the end may be introduced into a suction flask and the rate of filtration accelerated by an air-pump.

The first asset a prospector should acquire before attempting to prospect a lode is some knowledge of the constitution of lodes, and particularly of the distribution of ore in a lode. If this knowledge has been obtained he will certainly prospect his particular vein by sinking a shaft and driving levels along it, thus preparing the way for systematic development. But the man who only knows the ways of certain detrital deposits will assuredly object to the expense of sinking and driving, and will perhaps argue that drilling holes from the surface through the lode will answer just as well. As hand-boring tools like auger and sand-pump would be unable to do the work in most cases, he uses the best instrument for the purpose, a diamond-drill; but as he objects to the expense of sinking and driving he will limit himself to a machine giving a small core, at most 2 in. diameter.

High-Duty Gravity Stamp-Mills

By Peter N. Nissen

*Although the gravity stamp-mill has been in use for generations, I venture to state that it is not as generally understood and consequently not as thoroughly appreciated as its merits warrant. Possibly this is due to the great simplicity and seeming crudeness of its construction and the tendency to regard anything simple as unimportant and unworthy of serious study. However, the most interesting facts are often concealed in the simplest forms, and it is safe to say that nothing is of too little importance to merit investigation. This is especially so with the gravity stamp-mill, for in spite of its simplicity and seeming crudeness it is susceptible of the most delicate adjustment, its efficiency depending in a great measure upon the skill [illegible] devoted to it. It is interesting at this stage to [illegible] as a result of reliable tests that the well designed gravity stamp has proved to be the best [illegible] for crushing within the prescribed limits, as will be shown in these notes.

It has been demonstrated in many fields that in the items of power, labor, wear and tear, the cost of running stamp-mills is lower than for any of the other known crushing machines. In addition the stamp-mill covers a wider field in its work than competitive machines, since the size of feed for stamp-mills ranges from over 3 in. to fine sand; therefore its [illegible] as a crushing machine is greater. Every practical man knows that it is almost impossible to maintain the product from ore-breakers at the required size for more than a short period. This fact adversely affects work by rolls and Chilean mills, the feed for which must remain within the size governed by the diameter of the rolls or edge runners if they are to perform efficient work. Tube-mills are limited in their feed to a size not exceeding ¼ in., while ball-mills, although not so limited in size of feed, cannot possibly compete with stamp-mills in view of the enormous wear and tear on balls and liners in crushing the ore of the Witwatersrand.

The history and development of this excellent machine has been ably recorded by many writers. It is therefore not my intention to attempt any further elucidation of the subject, so far as the development of the multiple stamp-mortar battery, having sets of five stamps, is concerned. It is generally agreed that in spite of the length of time this machine has been in use, and while many improvements have been made in an effort to get the best results, it still remains a very imperfect machine. Much thought has been given to the present design for the rectangular mortar for five stamps [illegible] conditions of service, and many types have been [illegible], all of which adhere to one general principle and differ only in detail. [illegible]

Since the function of the stamp is one of crushing the greatest quantity of ore [illegible] large pieces, in the centre of the die face, renders it impossible to expect really efficient work from the stamp. Of equal importance with a controlled feed is the positive discharge of the crushed ore when reduced to the desired size. The rectangular mortar, having a screen on one of its longer sides, does not suggest a logical method of dealing with the problem. By the order of drop necessary to force the ore from one die to another, waves of motion are set up from end to end of the mortar, and only that material adjacent to the screen can be discharged. Double-discharge mortars might have improved these conditions, were they not still more difficult to feed, owing to increased width and the necessity of having to introduce the ore higher in the box, besides other faults of design.

It is not within the limits of commercial possibility to make the multiple-stamp mortar of sufficient weight in itself to secure the necessary inertia for effective crushing. It is therefore important that it should be securely fastened to a foundation having great weight and solidity. In a mortar with the blows of the several stamps acting on different sections of the casting with great rapidity, the greater the length the more difficult it is to hold securely on the foundation. Regardless of the skill exercised in fitting the mortar to the foundation, a certain rocking tendency exists, due to its being struck at alternate ends by the falling stamps. It is difficult to keep the foundation bolts tight; in any case, they are liable to stretch and easily break, due to the strain. Certain internal stresses exist in the mortar casting, due to its design, and this eventually breaks by the repeated blows.

Coming to stamps weighing above 1250 lb. and up to 2000 lb. each, we find the same diameter shoes and dies are used in all cases, so that the mortar need be no longer. Attention has been drawn to this fact by several writers, and rightly so, for there must be a correct relation between the area of the crushing members and the weight of the stamp, on rock of a certain hardness and toughness, to get the highest efficiency from the blow. Given the same length of mortar, to increase the weight of the stamp, it becomes necessary to use longer heads and heavier tappets. It is apparent that this is not the most desirable way of obtaining the object in view, because it raises the centre of gravity and increases the distance between the face of the die and the lower guide. A more rational way of accomplishing this object would be to increase the diameter of the head. This, however, would demand a longer and heavier mortar to accommodate the larger stamps and thus exaggerate the rocking tendency, besides increasing the distance between the cam-shaft bearings, which is undesirable. It is well known that there are limitations to the diameter of cam-shafts, since the longer the shaft the greater the velocity of the cam at the point of engaging the tappet, due to the greater distance between centre of cam-shaft and centre of stem.

It has been proved that heavy stamps are better crushing machines than the lighter stamps, within certain limits; therefore, since the heavy stamp is desirable, and as ordinary five-stamp battery construction does not lend itself to use with the very heavy stamp, a new design had to be evolved. To render the use of the heavy stamp possible, different principles of design should be adopted, so as to [illegible] the desired greater crushing capacity with sound mechanical construction.

[illegible] New York, is the owner of the American rights.

*[illegible] a communication to the [illegible] Chem. Met. & Min. Soc. S. A.

Goldfield Consolidated Report

The monthly report by J. F. Thorn, general superintendent, shows that during November the total production of the Goldfield Consolidated Mines Co. was 28,628 tons, containing $766,352, or an average of $26.77 per ton, the whole being milled with an average extraction of $25.28 per ton, or 94.4%. The total net profit was $510,468, or $17.83 per ton. During the month 3764 ft. of development work was performed. The total cost of mining, development, milling, office, and general expense was $7.49 per ton, distributed as follows:

Mining:		
Development	$1.09	
Stoping	2.47

At the Clermont the 401-sill has been extended, and produced 36 tons of ore which averaged $58.08 per ton. The 413-sill was again extended, and produced 235 tons averaging $53.74 per ton. The 410-X, an intermediate between the third and fourth levels, and in the foot-wall of the 408-stope is being driven in $15 ore. The east end of 420-sill on the 750-level has been extended about 35 ft. and produced 183 tons, which averaged $19.43 per ton. The 555-drift in the hanging wall of 510-intermediate, between the 750 and 900-ft. levels, has produced 231 tons, which averaged $13.44 per ton. The 521-sill on the 900-ft. level was extended, and produced 183 tons, which averaged $28.11 per ton. The Grizzly Bear shaft has been sunk to a point 20 ft. below the 1300-ft. level, and a station cut, preparatory to driving the 1300-ft. level.

In the Mohawk the 3-E sill being cut out of the No. 20 and No. 21 cross-cuts near the Sheets Ish workings, was considerably extended, and produced 849 tons, of an average of $44.44 per ton. The 3-D sill, also near the Sheets Ish workings, which is being cut from No. 13 drift, was extended, and produced 424 tons, of an average of $99.63 per ton. The 354-sill produced 118 tons, of an average of $49.19 per ton. The 345-sill, just south of the 354-stope, on the 450-level, produced 212 tons, of an average of $14.26 per ton. The 495-intermediate, between the 450 and 600 levels, produced 388 tons, averaging $13.23 per ton. The 499-drift over the 413-Clermont stope produced 56 tons, of an average of $21.50 per ton. In the Red Top, No. 352, the cross-cut in hanging wall of 305-drift mentioned in the last report, produced 417 tons, of an average of $60.56 per ton. The Hazel shaft was sunk a distance of 90 ft. below the 718-level during the month. The raise from the first level of the Combination, 20 ft. northwest of the 136-stope, has disclosed $15 ore. The 402-stope, near the bottom level of the mine, has been deepened, and produced 802 tons, averaging $74.62 per ton.

Traversing Between Two Known Points

It is sometimes necessary to traverse between two known points which are plotted on a map, but which are too far apart to permit seeing from one to the other; such as two section corners or wires hung in two raises underground. In such a case it is necessary to assume a bearing for figuring latitudes and departures from one point to the other. Next it is usual to figure the course with the corrected bearing obtained from computing the bearing between the two points and comparing it with the known bearing. This second computation can be obviated by plotting the results of the first one on a small piece of tracing cloth and orienting the two known points over the same points on the map.

Much Ado About Nothing

London Correspondence.

A striking example of a political mare's nest is afforded by the case of the Anglo-Westfalian Kent Coal Syndicate. A group of parliamentarians, keen on keeping their names before the public as clever critics, have agitated against the granting of a mineral lease to the above-named company, and have raised the question in Parliament. "Is it right," they say, "to allow the confounded German to own coal land in Kent and to sink shafts and produce a high-class quality of steam coal in our own territory just under our very noses, on the English Channel and the Straits of Dover? Also, is it not a scandal that the landlord that granted the lease should be one of the Government Departments that happens to hold the land in trust for the Church of England?" and so *ad infinitum*. The facts, however, put a different complexion on the matter. The English company that has the business in hand decided to employ one of the German methods of sinking through watery strata by means of which the iron lining of the shaft is built up as the shaft is excavated; so some of the officials connected with the company are necessarily representatives of the German engineering firm. It is a wise policy to adopt some sort of protective sinking, for the overlying chalk has caused enormous difficulty to the other companies working in the Kent coalfield. For instance, at the Tilmanstone and Snowdown shafts, the sinking to the coal seams is continually being postponed by flooding, and the expensive pumping plants provided appear to be incapable of coping with the flows. Even if sound shafts are sunk, it is an open question whether the workings will not eventually be flooded from other irruptions. Therefore the anxiety will not be at an end when the Anglo-Westfalian shaft at Chislet, near Canterbury, is completed, and the policy of keeping the German experts in control afterward is a good one. But the German invasion does not warrant a public scare, or the mobilization of the British fleet.

Copper Mines in Turkey

The copper mines of Arghana are in a region which is rich in mineral deposits. They are situated to the northwest of the town of Diarbekir, on the upper reaches of the Euphrates. The ore was discovered so long ago as 1096, and, according to an authority, the cupriferous deposits extend over a surface of 12,000 metres square, and contain 30% copper, 30% sulphur, and 40% iron. It occurs in a huge lenticular mass enclosed in volcanic rock, which has thus far been worked to a depth of 30 metres, but there is evidence to show that the deposit is not exhausted. The vein has a mean thickness of 15 metres, and contains an average of 25 to 30% metal. Some of the veins contain as much as 50% pure metal.

Formerly the mines were the property of the community, but of recent years the Government has bought 40% of the deposits, which it works at an annual cost of $T15,000, and by means of a shaft 80 metres deep. This is all but complete. At one time the ore was smelted at Tokat, 380 kilometres distant; but the smelting works have fallen into disuse, and now, after being treated in the crude state on the spot, the metal is conveyed on camel-back to Alexandretta, 1400 tons being shipped annually. As is the case with so much of the mining industry in Turkey, the greatest difficulty to the economic production of ore is the lack of fuel, and in regard to the Arghana mines the charcoal used in smelting the ore has to be brought a distance of about 60 kilometres, owing to deforestation. So important is this mineral deposit that a German-American group proposed to the Government to make it a loan of £4,000,000 for the right of co-working the line.—*The Near East*.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Enemies of Society

The Editor:

Sir—Believing that no good work should be allowed to pass without a word of encouragement or praise to the workman, it gives me great pleasure to congratulate you upon the publication in your issue of December 9 of the editorial entitled 'Enemies of Society.' You have gone to the very heart of the subject when you say that the danger to society lies in "* * * the obscuring of the bad unit in the larger aggregation of units." And surely the only remedy is to "cut out the rotten spots", whether they be found skulking in the aggregation of units composing the humblest social stratum, or whether they are exposed in the highest social or political atmosphere, as did Wharton Barker before the Senate Committee on Interstate Commerce, on November 28.

It is too early yet to view clearly the astounding McNamara case. I remember that an early investigation by Government experts resulted in the opinion that the explosion in the Times' building could not have been of dynamite, but that it probably was illuminating gas. If this is so, then a much deeper conspiracy than a dynamite plot lies behind the McNamara "confession." I am not surprised that Clarence Darrow should be found "discredited before the world." He was that before part of the world long ago, when he first took up his demagogic defense of organized labor. Great enemies of society may be brought to light before the final settling of the Otis-McNamara-Darrow dust.

DAVID R. SMITH, Jr.

Guaymas, December 13.

Pitch of Ore-Shoots

The Editor:

Sir—Since my communication of September 2, I have read W. H. Storms' communication on 'Pitch of Ore-Shoots' that appeared in your issue of that date. When groovings (also 'cross-fractures') do exist, and there is no stronger evidence to go on, I should expect the ore-shoot to angle across, rather than with, their dip. That the ore is likely to follow the general trend of the troughing, as Mr. Storms suggests, seems to me correct: space favors deposition. And, considering only the physical factors influencing ore-shoots, this assumption *might* also apply to those veins where the 'pay-ore' is in the narrower parts; the higher-grade ore following the trend of the larger portions of the vein, that is, along the edges of swells or between a series of these. The difficult point to determine, at least in a prospect, is the general trend of such possible troughing.

I submit that 'cross-fractures' and the wall-grooves of variable depth are useful indications of shoot-pitch. In the mineral deposits of the Southwest (including most of Mexico) the impression left with me is that the deposition of the present ore is about the last thing that has happened. (Many 'faults' when run to ground are found not to be post-mineral, but, on the other hand, the ore appears to have commenced forming from the locus of such 'faults'. This is illustrated in some of the mines in the Johnson district, Arizona.) And where there have been later movements these are apt to follow the same general directions as those that first formed the fissure, such movement being indicated by mineralogical and structural features of the filling and walls, and sometimes only indicated by cross-fracturing. This relation of cross-fractures, groovings, and shoot-pitch may be illustrated with a couple of scraps of corrugated roofing. These placed together might be taken to represent the vein at the moment of fracture. Then by slipping the sheets on one another it will be seen that any possible line of movement would angle across the trend of the troughs thus formed. Even if the two sheets be slipped along their corrugations, any change in the dip of the vein, or any warping, would cause similar trough-like spaces, as illustrated by turning the sheets at right angles to their first position, and giving them the same up-and-down movement. This change of vein-dip, and of width, should be noted in the plotting suggested in my letter in the issue of September 16, and in those cases where such changes occur a cross-section of the vein should be shown.

W. N. CUMMINGS.

Tucson, December 3.

Is 'Cheap' Labor Economical?

The Editor:

Sir—After reading the letters that have appeared under the above title, or caption, it seems to me that a definition of terms is wanted. What is meant by 'cheap' labor, and what is meant by 'dear' labor? So far, the question has been confined to the relative merits of African and Mexican, Chinese and Indian labor; but no attempt has been made to refer this so-called 'cheap' labor to any definite standard. However, from some of the statements made, I assume that 'dear' labor means white labor, and 'cheap' labor means native labor in countries outside the United States and, perhaps, the northern part of Europe. It is interesting, of course, to note the merits and demerits of the various races; but I fail to see how it touches the question at issue. I think what is really meant by the question (and therefore the whole gist of the matter) is this: Which is the more economical—high-priced skilled labor, or low-priced unskilled labor attempting to do the skilled laborer's work? In my opinion there is no room for question, and I have had over thirty years' experience of all kinds of labor—all, or nearly all, nationalities and races, I mean. My opinion then is: That there is no economy in cheap unskilled labor, no matter whether it is the labor of the manager or superintendent, or the labor of the foreman, the shift-boss, or the miner. Many promising prospects, many a mine in the making, has been ruined by unskilled 'cheap' labor in the 'office,' and many a mine has been forced to close down because of the effects of unskilled labor underground. I also think that the whole question is one of intelligence. The more intelligent the miner is, the more valuable he is. Mining is a trade as much as carpentering, blacksmithing, or any other form of skilled labor, and it is a trade that calls for as much skill and intelligence—if not more—as any other trade. Moreover, mining is a trade that no one man can learn thoroughly in all its phases. It takes many years to make a good all-around miner, and he should be paid well. I am quite confident that, in deep mining especially, a crew of good skilled miners can do more work, and what is more important, far better work, than twice their number of unskilled laborers, or only half efficient miners (?). 'Cheap' labor, no matter whether it is African or Mexican (peon), Chinese or Korean, American or European, is the very dearest form of labor when it is only hired because it is cheap, or because highly skilled labor is dear. It may be stated, as a general proposition, that when a mine will not pay for the skilled labor that is necessary to properly extract the ore, it is time to close it down. To sum up, it is the skill, the ability, to mine intelligently and efficiently, that commands the high price, so-called, for underground work, just as it is the skill and ability to manage mines intelligently and efficiently, that commands the high price, so-called, paid for the office work, the supervisional work.

CHARLES R. GENT.

Trimmer, California, December 18.

VERMONT made a production of 1935 lb. of blister copper in 1910. The most important deposits of the State are those near Ely. These deposits have been worked at intervals since 1821 and have made a considerable contribution to the copper output of the country.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

IN ORDER that a screw conveyor may deliver centrally to a bucket elevator, it should be equipped with both right and left hand flights placed on opposite sides of the elevator.

LEAKY VALVES may be repaired in the following simple manner. Remove the hood and sandpaper the brass valve disc bright where it sets on the seat, then go all around with a hot soldering-iron and place a coating of solder all around it; when it is put back it will be found perfectly liquid tight. This scheme is not effectual where high pressure steam is used, as it will not stand long in this case.

AN adjustable drop-light can be easily made. Cut a spring shade-roller to any convenient length for attaching, by the usual sockets at each end, to rafters or other supports over the spot where you wish an electric light to be suspended. Attach a cord to the roller and wind it so as to coil the spring when it is pulled down, just as a shade would do. Tie the other end of the cord to the insulated wire of your electric light. Of course, the latter can now be made to hang at any desired elevation.

THE difficulty of screwing flanges on pipe of large size is well known to those who have tried it, as these flanges are made so short that it is difficult to grip them in any way. An expedient which is amply satisfactory in many cases is to place bolts loosely in the bolt-holes in such a manner that a large stick of timber will be held between them, the stick acting as a lever by which the flange can be turned. The method will commend itself for its simplicity and the rapidity with which the work can be done.

TO REMOVE PAINT from an iron tank, take lime and mix with common lye into a thick paste by the addition of water, and apply over the surface of the metal with a mason's trowel to the thickness of about ⅛ in. After allowing the mixture to remain a short time, wash off with a hose, and most of the old paint will be entirely removed, the remainder being easily scraped off. If the tank has several coats of dried paint, two or three applications will be necessary before the entire surface is clean.

CORUBIN is a new artificial abrasive manufactured abroad, which has recently been put upon the market. The material is produced from the slag resulting from the reaction between aluminum and chromium oxides. It is practically pure alumina containing a trace of chromium oxide, which gives it a red color. On account of the high temperature at which it is manufactured it is free from combined moisture. It is produced in three grades—coarse, medium, and fine—and is sold only in the proportion of two parts coarse to one each of medium and fine.

REFINED grades of plaster are used in dental work, also as cement for plate glass during grinding, for making pottery molds, stereotype molds, and molds for rubber stamps, and as an ingredient in patent cements. A large quantity of gypsum is used in the raw state as a retarder in portland cement. Considerable quantities are ground without burning and used as land plaster or in fertilizers. Smaller quantities are used unburned in the manufacture of crayons, paper, imitation meerschaum and ivory, calcimines, water paints and tints, and dry colors, notably venetian reds. When used in excess in mixed paints, gypsum is regarded as an adulterant. The unburned and dead-burned forms of gypsum may be used to a certain extent with oil paints, because they are not very active chemically.

AN amended location notice, not a relocation, should always be placed upon the ground and recorded, when changing boundaries in any way. The difference between an amended location and a relocation should be fully understood. An amended location is made for the purpose of preserving all the desired rights and privileges obtained by the original location. A relocation is a new location of the ground of a former and abandoned or forfeited location. If the location is made by the owner of the former location, it is technically a waiver of all rights under the previous location. Still, the exact rights under a relocation by the original locator or owner are indeterminate, for both miners and courts hold that it has some relation back to the original location, the strength of the relation depending mainly upon whether any adverse claimant or intervening location has come between the two locations. By making a relocation instead of an amended location, the value of any previous work is lost for patent purposes.

PHOSPHATES containing 35% of P_2O_5 are produced in Sweden by a recently devised process. During the exploitation of the Gellivara mines, enormous quantities of ore too poor in apatite to be utilized were left. Now that the immense electric power-house supplied by the Porgus waterfalls has been constructed, it is proposed to work these heaps of débris. The poor ores are first sorted mechanically, and then treated by the process devised by W. Palmer, of the Stockholm University. The diphosphate of calcium can be obtained by subjecting the apatite to the action of hydrochloric acid produced by the electrolysis of common salt. The salt is regenerated, and can be again used. For 1 kw.-hp., 3 tons of the diphosphate of calcium can be produced annually from 11 tons of the residue containing apatite. It is estimated that Gellivara will be capable of supplying 11,000 tons of phosphate per year, for which 5000 to 6500 hp. will be necessary. There are also similar large waste heaps at Kirunawara, Svapparara, and Ekstroeberg, equally amenable to electric treatment.

AGRICULTURAL entries on public land are made subject to any accrued rights, and consequently the vein of a location older than the agricultural entry or patent, may be followed into the agricultural land. A location made subsequent to the issuance of the agricultural patent confers no right to follow its vein into the agricultural ground, but the status of a piece of agricultural land between the time when the first rights were initiated on it under the agricultural land laws, and the time of making final proof and the issuing of the receiver's receipt is not known; apparently any location made before the issuance of the receiver's receipt would have extralateral rights into the agricultural land. In the case shown in the diagram, the point to be settled is, therefore, whether the location of the lode claim was made previously to the issuing of the receiver's receipt for the agricultural entry.

KALGOORLIE, WESTERN AUSTRALIA

October Gold Production $2,493,000.—Lake View Consols and Oroya Exploration Merger.—New North Boulder to Erect Mill.—Water Shortage Serious.

The October gold yield from all mines in this State was valued at $2,493,000. The principal mines returned as under during the period:

Name.	Tonnage.	Yield.	Profit.
Associated	10,379	$75,400	$5,700
Associated Northern	1,296	15,400	.....
Burbanks Main Lode	1,762	23,000	.....
Golden Horse-Shoe	26,890	161,900	6,900
Golden Ridge	2,760	27,500	8,700
Great Boulder Perseverance	21,243	116,000	6,700
Great Boulder Proprietary	17,482	238,500	128,500
Great Fingall	6,089	68,500	18,500
Hainault	5,200	38,500	1,500
Ivanhoe	20,871	205,000	90,200
Kalgurli	10,940	110,400	45,300
Lake View Consols	8,145*	8,940	1,200
Lake View & Star	17,883	105,000	16,900
Oroya Black Range	4,710	47,100	16,600
Oroya Links	10,050	59,200	9,900
Sons of Gwalia	14,035	135,000	49,200
Sons of Gwalia South	2,273	14,500	4,100
South Kalgurli	9,590	60,100	10,500

*Old residue.

The amalgamation of the Lake View Consols and Oroya Exploration is announced, each company having equal share in a company of 900,000 shares of $2.40 each, 180,000 being held in reserve. These are rather holding companies than actually running mines, and they have interests all over Australia, and in Nicaragua and Burma. Both had large dumps of residue to treat by vacuum plants; but the latter has finished its lot and handed the plant over to the Oroya Links. The Hannans Star, here, had a vacuum plant at work on its old dumps, but it has been shut down, as the gold content was too low. Out of five vacuum plants about Kalgoorlie, with a monthly capacity of some 50,000 tons, only 10,000 tons are of fresh mill-slime, this being at the Oroya Links, the rest being on old dumps. There also are the Ridgway machines on the Great Boulder, which can deal with 20,000 tons. There is nothing like accuracy in all departments of mining, but for a company to return 834.24 tons milled for 401.81041 oz. worth £1706.77917, giving an average of £2.0506 per ton, seems a trifle over the margin.

The New North Boulder company, situated on the east side of the Associated, has decided to erect a mill to treat its oxide. The plant will consist, for a start, of a Campbell gas-engine and a 5-ft. Huntington mill. The sulphide ore, typical of our eastern belt, will be opened up in the meantime. This company crushes periodically and has just returned 400 tons of sulphide ore for $12,000; and 1000 lb. of specimens for $3700.

Mentioning specimens reminds me of a recent crushing from Mulgabbie, a few miles from Kanouna, where 5600 lb. of ore yielded $16,000. One by one the outside districts are running short of water, and appealing to the Government for help. This has been an unusually dry year, and no rain may be expected until next March or later. The Marvel Lock district, south of Southern Cross, is to be connected with the Water Scheme main by a 5-in. pipe, costing $55,000. The Ora Banda district also wants a supply, while the Mines Department is improving the supply between Yuanmi and Paynesville, the latter being the new district developed in the Murchison field. There are, among others at Paynesville, the Aster, Bovania, Carnation, Sweet William, and Thistle prospects being opened up with rather promising results. The third named is the original Payne's Find, and contains three lines of lode formation, 70 to 300 ft. apart. Assays over 18 to 30-in. width at various depths to 30 ft. show $12 to $25 per ton. Trenches aand shallow shafts have been sunk on the others named, with such favorable showings that they are under option to an Adelaide concern, which had interests at Tanami, in the extreme north of this State, and also at Bullfinch.

The Miners' Phthisis Commission has finished taking evidence and will consider its report for Parliament. An Italian contractor at the Great Fingall mine, in the Murchison district, stated that of 250 men working for him, 100 had died, and the inference was by fibrosis. Later witnesses included insurance company managers, secretaries of friendly societies, and the like. They gave their views on compulsory insurance of miners and the like. Many believe if the State took on this business, it would be guesswork as to which workers suffered from pulmonary complaints. The past financial year of the municipality of Kalgoorlie showed its revenue to be $137,500 from 8700 people, including profits from lighting, markets, and other sources. The bank overdraft is $31,200. The electric light receipts were $100,000, of which $21,500 was profit.

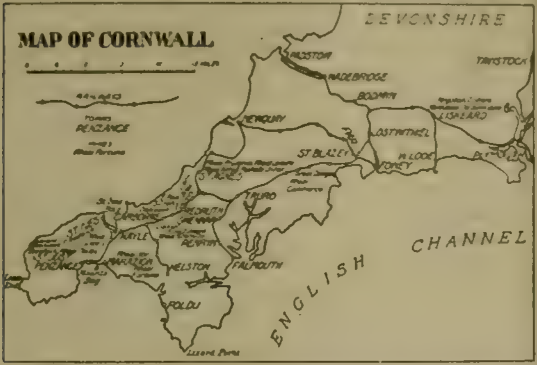
LONDON

Warm Contest for Control of East Rand Proprietary Expected.—Anglo-French Exploration Co. Objects to Amalgamation with Farrar Interests. — Cornwall Notes.

The case of the East Rand Proprietary mines continues to absorb the attention of English investors. I have kept your readers pretty well posted in the developments, so I need not recapitulate here. The exposure of the failure to make good the promises of output and profit has led not only to the resignation of the manager, Sydney Penlerick, but to a notification of the intended resignation on the part of Sir George Farrar and the rest of his supporters on the board. The two nominees of the Wernher-Beit-Eckstein group (or the Central Mining & Investment Corporation, as it should now be called) also have intimated that they will resign in order to prepare the decks for a battle royal. The resignations will be tendered at the annual general meeting to be held at Johannesburg at the end of February. The two sides, Farrar and Central Mining, are now actively conducting their canvass among English and Continental shareholders, and naturally the decision will be settled by proxies and not by personal attendance at the meeting at Johannesburg. The Central group members are recommending E. A. Wallers and F. Raleigh, two of their best financial men, as directors, and H. Ross Skinner as manager and also as managing director. The general opinion here is that the Farrar group will have to retire into the background, for though it is easy to accept their assurance that they did everything for the best according to their lights, yet it is obvious that they made a bungle of it. On the other hand, there is opposition shown in some quarters to the absorption of the company into the Central control, for it looks too much like the thin end of the wedge of monopoly. Personally, I do not see that this argument is effective in this case, for the Central group can point to great successes in administration and technical organizations, and on this 'platform' at the present juncture they are bound to win. There probably will be no further news with regard to the East Rand Proprietary until the meeting two months and a half hence.

In the meantime the Farrars are being worried by opposition in a different quarter, and there seems to be a likelihood of a split between them and the Anglo-French Exploration group. The trouble has arisen through a proposition made to amalgamate the Rezende and Penhalonga companies, operating in the Umtali district of Rhodesia. Neither company has been a marked success, but the Penhalonga has been in the control of the Anglo-French-Farrar group for thirteen years, while the management of the Rezende was transferred to them only a year or two ago. Since then the two companies have been directed and managed by the same boards and the same staff at the mines. Seeing that they own two parallel sets of deposits not far from each other, an amalgamation seemed reasonable, especially in view of the fact that the engineer, C. R. Pinder, and a firm of first-class accountants had agreed upon terms which were fair to the shareholders in the respective companies and suitable to the management. However, the directors representing the Anglo-French group dissented and resigned. It is difficult to fathom the motives for this quarrel, either the Farrar management is at fault in this case, as in the East Rand Proprietary, or the Anglo-French people have taken advantage of the temporary discredit of the Farrar management to make an attempt to capture the control.

The news from Cornwall this week contains the usual mixture of encouraging and depressing items. The most pleasing features are the estimated increased profits, both at Dolcoath and South Crofty for the year just ending, and the publication of the first results at the dredging work on the tin gravel of Goss Moor. These gravels are being worked by F. M. Lush, on behalf of a company of which J. H. Collins and C. G. Lush are directors. The system is one adopted in Australia, where the gravel banks are loosened by hydraulicking and the gold recovered on a floating barge. The first campaign has given a cost of 1s. per cu. yd.; but in view of the usual difficulties in connection with a new plant and in teaching the workmen, it may be taken that this figure will be substantially reduced before long. The average recoverable content is $1\frac{1}{2}$ lb. black tin per cu. yd., which with concentrate selling at £110, the present current price, would make the value of the recovery worth 1s. 6d. per cu. yd. As a matter of fact, the concentrate is of a higher grade than even the best products of the lode mines, for the percentage of the metal varies, never less than 73%, while the absence of other minerals is also in its favor. I am quite hopeful that the first six months' run will yield a substantial profit. Another interesting venture is that of the Cornish Tailings Co., which is re-working the old dumps at Carn Brea & Tincroft. The material is reground in tube-mills and treated on tables and buddles. Though the extraction is still very incomplete, the recovery is sufficient to yield a net profit of £1000 per month, not at all a bad performance in Cornwall.



The depressing news from Cornwall comes from St. Ives and Dowgas. In these columns three months ago, I mentioned that the St. Ives Consolidated would be requiring still more capital, following the usual course of the Schiff-Dietzsch group. Old properties and dumps are bought up right and left, and magnificent machinery erected for the treatment of the expected ore. Now a further installation of stamps and tube-mills are to be erected, and £120,000 of debentures are to be offered for subscription. The rich ore about which so much was heard has apparently vanished; for, instead, large blocks of low-grade ore are now the strong point. But 23-lb. ore will not pay under anything but the most skilled and economical management, and this is not to be found at St. Ives Consolidated. The Falmouth Consolidated, belonging to the same group, does not fulfil the wonderful promises of a year and two years ago, when sufficient ore to feed 1000 stamps was airily discussed. Though the plant has been running for more than a year, the product is a paltry few tons per month. As regards the Dowgas, the news is that the surface plant is to be sold by order of the receiver in bankruptcy, for the benefit of the debenture holders. Quite $100,000 was spent on surface equipment and the plant had a capacity of 100 tons per day. But, unfortunately, underground work was neglected, and no more money could be obtained to continue it. I believe there is plenty of tin there, and a competent mining man would make a good bargain by bidding for the plant and re-starting the property.

NEW YORK

Copper Merger Impossible. Favorable December Producers' Report Expected. Production Notes. Live Oak and Inspiration Consolidation.—Scramble for Butte Coalition. Other Developments.

The copper situation has continued to furnish the chief topic of discussion in mining circles during the week. The outstanding feature in the metal market is the apparent attempt to make the most of every bull argument, all of which is accompanied by an evident feeling of uneasiness and a decided lack of confidence in the stability of the market. Interviews with some large brass manufacturers confirm the statement that stock piles are very low and that many of them are anxious about supplies during the next few months. Copper-selling agencies have adopted a somewhat high and mighty tone, with some sales made at $14\frac{1}{8}$; this is a part of a campaign waged to stampede the reluctant domestic consumers and induce them to stock up with normal supplies. While combinations in restraint of trade are being counted as outlaws and several are on trial for corporate existence, it is out of the question for any organization to acquire control of the copper metal market. A copper merger is an impossibility at present, and in the present state of the public mind would hardly meet with anything but a hostile greeting; nevertheless, it is to be deplored that foreign interests should reap the major part of the benefits arising from cheap copper. The German manufacturer has found many uses for copper bought at 12c., that are and will be impossible to our home consumer with copper bought at 14c. and upward. A feature that confronts the copper producer is that cheap copper makes for many uses of the metal and a record consumption, while every half cent added to the price makes tremendous gross profits on the country's total output but at the same time works proportionately for a decrease in consumption. A very favorable report is looked for covering December output and consumption, and, unless something untoward develops, the copper market may be expected to be in full swing by the middle of January.

There are many indications of increased activity that are due to the prospect of higher metal prices. Anaconda, for one, is expected to increase production some 6,000,000 lb. per month. There are numerous smaller properties that are in the same position as is Anaconda. They have had a breathing spell in which to work out cheaper cost-sheets and to complete new development work, and they now are prepared to show, not such large increase, to be sure, as is mentioned for Anaconda, but in proportion, and in the aggregate to make a very important increase in the red metal output. While specific details are not available, there is some talk of a corner in copper engineered by a London syndicate, and if there is any foundation for the rumor, it may only tend to increase the stubbornness of the domestic user of copper, who is firm in his belief that no organization can absolutely control the copper market. Just one report by the Producers' Association showing that refinery output is once more running beyond the combined demand of consumers at home and abroad, and all the life with which the present situation is charged will disappear. The critical period of the market will be the first quarter of the coming year. What is being done now is simply by way of an attempt to discount the future.

The merger, which was to include the Miami, the Live Oak, and the Inspiration, and which was alternately reported as consummated and then said to have been declared impossible, finally resulted in the consolidation of the Live Oak and the Inspiration. The first step has been taken by the incorporation in Maine of the Inspiration Consolidated Copper Co., with an authorized capital of $30.000,000, in 1,500,000 shares, par value $20. It is not expected that all of this stock issue so authorized will be taken up in making the necessary exchanges for the present outstanding stock of the two companies; there will be a substantial treasury reserve held for future needs of the new company. The terms which are to be offered to the present stockholders have not as yet been announced. The immediate erection of a large reduction plant is planned.

The leading issue in the copper share list traded in New York during the week has been Butte Coalition. The announcement of the early dissolution of the company, involving, as it does, the distribution of a half million shares of Anaconda, 3000 shares of International Smelting & Refining, and an additional block of Anaconda, representing the interest which the Butte Coalition had in the Alice Gold & Silver, amounting to some 20,000 shares of Anaconda, has created something of a scramble in the stock market. The International stock, which cost the Butte Coalition some $100 per share, has been sold to the Amalgamated around the present market price of $130; there is in the Coalition treasury some $3,500,000 cash; with the sale of the smelting stock, there will be something over $4,000,000 to be paid as a final dividend. The present market price of Anaconda is about $38, which would give the Butte Coalition holding a value of $19,000,000; with the $4,000,000 cash added, making a total of $23,000,000, equivalent to $23 per share upon the 1,000,000 shares of Butte Coalition. The market has established a parity in the two issues and, on the strength of the market activity created, is bidding full price for Butte Coalition on the basis outlined. The distribution of the Parrot's assets is also announced, though in the latter case dissolution will not immediately follow, as there is some litigation pending which prevents the giving up of the company's charter at present. The market feature of the situation is the large addition to the amount of Anaconda stock in the hands of the public and available for trading purposes. It is rather anticipated that there will be something doing in Anaconda, hence the scramble for Butte Coalition shares in order to get the exchange privileges.

The International S. & R. Co. is to build a lead refinery which, it is expected, will be situated in or near Chicago. The question of situation is dependent principally on freight rates.

A protective committee has been formed to receive deposits of the bonds of the La France Copper Co., a subsidiary of the United Copper Co. The La France company has defaulted in its interests since January 1908; the interest payments were guaranteed by the United Copper Co., which likewise has failed to pay, though it has given notes in lieu of payment; the notes, however, were not paid when due, and the present step is the first in some form of reorganization, to be worked out later. The La France company owns the Lexington mine, in Walkerville, at Butte, and the concentrating plant at Basin. The defaulted bond issue is for $2,000,000.

The Ahmeek, which was the principal contestant against the proposed Calumet & Hecla merger, is justifying the claims made for it in resisting the planned consolidation. The property is now turning out the cheapest copper which comes from the Lake country and producing at the rate of about 15,000,000 lb. per year. Present plans include development underground and enlargement of equipment sufficient to bring production up to 25,000,000 lb. per year within a year or fourteen months. The dividend rate of $2 per share quarterly has been increased to $3 per share quarterly.

Estimates are being made of the probable output of the Cobalt district for 1911. It is generally conceded that Cobalt is carrying the peak of its load, and that this year will be a record-breaker for the future as well as for the past eight years of its life as a mining camp. When the final clean-up is made for the year, Cobalt production will probably reach 32,000,000 oz. of silver as against nearly 30,000,000 oz. for 1910. Cobalt is producing nearly 14% of the world's output of silver, and as a poor man's country stands alone among the mining districts of the world. No other field has ever produced so much in net profit. Cobalt dividends now total nearly $30,000,000.

The fact that some of the large producers are apparently nearing the end of their productive careers, on anything like the present scale of magnitude, is responsible for the decline in market interest which is now almost negligible.

BUTTE, MONTANA

Rosy Future in Zinc Production Predicted for Butte Process.—Basin Reduction Works' Future Arouses Conjecture.—General Notes.

Many mining men believe that the Butte district is destined in the not far distant future to become important in zinc as well as copper production. Experts who have visited this city and made an investigation of the Butte & Superior mine and discovered that over 1,000,000 tons of ore was developed, and who then inspected the zinc property of W. A. Clark, have had no hesitation in declaring that the zinc industry would make Butte as famous as had its copper. During the month drawing to a close, with a shipment of about 500 tons per day, the Butte & Superior company estimates that it will net $47,000, and the claim is put forward that with similar shipments greater profits will be made when the company is operating its own concentrator, now under construction. The Butte & Superior is having an experimental plant erected for the purpose of giving the Peterson electric process a practical test. Should the process turn out to be what is claimed for it, the mines of the Butte district will be in a position to make a higher profit than at present. Mr. Peterson says that at present the cost of treatment to Butte operators is about $40 per ton, which he says is far out of proportion when it is considered that copper ores can be smelted at a much lower cost.

The assignment of the claim of the State Savings bank of this city to its interest in the Basin Reduction Works to George E. Shaw and F. E. Potts of New York, as trustees, has been filed for record with the clerk of the court, still leaves the curious in as much doubt as ever as to who put up the $158,920 to redeem the property. Nearly four years ago the Basin Reduction company, through W. A. Kidney as president and Henry Brunssen, treasurer, secured $145,000 from the bank and gave in return a promissory note. At that time F. Augustus Heinze was the prime head of the Butte Reduction Co. and was also one of the chief directors of the State Savings bank. No part of the note was ever paid, and nearly one year ago, H. Mason Rabourg, of New York, who was vice-president of the Davis-Daly company and supposed to be closely connected with Heinze, came to this city and took charge of the bank. He endeavored to collect on the note, but failed in the attempt, and then started proceedings which resulted in the property being sold at sheriff's sale on January 14 of this year. The bank bid the property in for the amount of the note with interest, and a few weeks ago it was announced that the property had been redeemed. It is believed that Shaw and Potts, who are named as trustees in the assignment, are acting for the bank, and that an arrangement has been made whereby W. A. Clark will take over the property. Mr. Clark's zinc property has been closed down for over three months, as there is not a mill in operation which is available for handling zinc ore. He had the Butte Reduction Works' concentrator fitted up with the latest machinery, and its destruction by fire was a heavy loss. If it should turn out, as is generally supposed, that Mr. Clark is going to take over the Basin works, he cannot get possesssion until July 1, as the Butte & Superior company has a lease on the concentrator which does not expire until the last day of June. There is an impression in some circles that the negotiations for a merger of interests between Mr. Clark and the Butte & Superior company are still pending.

It now looks as if the case of the Anaconda Copper M.

Co. against the Butte-Ballaklava company on a charge of extracting ore from ground alleged to belong to the former company will be called for hearing at the February term of court, but whether it will be tried here or in some other part of the State is in doubt. The ground has been laid out and excavation work is now going on for the construction of the Butte Central concentrator, upon which the real work of erection will start early in the coming year.

GOLDFIELD, NEVADA

Rumor Goldfield Con. Report Will Show Ore Reserves Opened Equal to Production of Year. Florence Goldfield Plans. General Notes.

Much interest attaches, here as elsewhere, to the forthcoming annual report of the Goldfield Con. M. Co., which will be submitted to the board of directors at the meeting in January. Although no definite intimation has been given of the contents of the report, it is said that it will contain a new estimate of the tonnage and value of the company's ore reserves; a feature of the mines that has been discussed pro and con for some time past, but upon which there has been no reliable information accorded the public. It is also stated, but not upon official authority, that the report will show ore reserves opened during the past year's operations equal to the yield in that period. This represents a sum of about $10,750,000 gross. Some ore of excellent grade has been coming from the old Jumbo workings, which have been cleaned out, and of which the shaft has been prepared for further sinking. The company's plant for the treatment of concentrate-residue, with a capacity of 75 tons per day, is nearing completion. Estimates have placed its cost at about $70,000 and it is expected to effect a saving of $80,000 per year.

Development has been resumed on the Florence Goldfield, and probably will be carried on along the lines planned before the destruction of the 40-stamp mill on December 2. The head-frame, equipped with automatic skips that were described recently in the *Mining and Scientific Press*, was built against the main mill structure, dumping the ore directly into the stamp-bins. This, together with the main mill structure and the store-house, was totally destroyed by the fire. The mill proper, according to officials of the company, cost $432,000. The hoist and compressor were not damaged, but it was necessary to cut both hoisting cables during the fire. A. D. Parker and Thomas G. Lockhart, respectively president and vice-president of the Florence company, are now in Goldfield and are engaged in going over the wreck and appraising the loss, in company with adjusters representing the Underwriters' Association of San Francisco, in which city the insurance was placed by Mr. Parker. They have not yet announced the amount of insurance carried, nor have they been able to determine whether any of the machinery has escaped total destruction. A formal meeting of the directors will be held shortly, when the future policy of the company will be decided upon and made public. Mr. Lockhart has been at Rhyolite, where he examined the 30-stamp mill of the Homestake-King M. Co., which was recently sold at auction to satisfy a judgment, and he was met there by representatives of the Homestake-King company. This has led to a report, which has not been officially confirmed, that the Florence company is negotiating for the purchase of this mill, which is said to be a modern well equipped plant in excellent condition. Two days after the fire a young electrician, F. L. Eubank, who had been in the company's employ for over two years, while climbing the perpendicular ladder in the main shaft, fell 40 ft. to the bulkhead at the eighth or 530-ft. level, and died several days later. Only five sets of timbers in the shaft were burned and these have been replaced, the old head-frame from the Hall Florence lease shaft has been installed over the main shaft, and the hoist, pumps, and compressor are again in operation, having taken out about 60 ft. of water that ran into the shaft during the fire. The shaft is now down 930 ft. and will be continued to a depth of 1060 ft. to provide a sump below the 1000-ft. level, where the main lateral work will be carried on. It is said that some rich ore has been exposed in old workings nearly under the site of the mill.

Work is now in progress that has for its object the further exploration of the Combination Fraction. This work is being done by the Consolidated company, being paid for by the Fraction company, and consists of driving to the south from the old Mohawk workings on the 450-ft. level to open up the northern part of the Fraction at that depth. Two years ago the Combination management drove a cross-cut on its 600-ft. level to the west and across the Combination claim of the Consolidated, in quest of the southern continuation of the main Combination vein, but no pay ore was found on this level. The belief is now expressed that the vein, in which the Hampton stope was opened farther to the northwest, has been thrown to the east by fault displacement and into the Combination Fraction territory.

On the C. O. D. Consolidated property the company is driving on the 600-ft. level, and lessees have exposed seams of exceedingly rich ore at two points, on the Gold Bar and Victor claims and near the 200 and 350-ft. levels. The rich seam varies from four to eight inches in width, and has yielded some sensational assays. Grab samples taken from several sacks of the rich ore, prepared for shipment from the Gold Bar workings, assayed a little under $3000 per ton, and a shipment will be made shortly that is expected to mill $600 per ton. Two other leases are working on the 600-ft. level from the Sills shaft and two on the C. O. D. claim, near the boundary of the Atlanta, making six leases in operation on this property.

SALT LAKE CITY, UTAH

High Metal Prices Boom Copper Production.—Utah Consolidated Increases Shipments.—Yampa Closes Down.—Other Districts Active.

The strength of the metal markets is having an immediate effect on the production of Utah mines, which are increasing their tonnage, especially in copper. At the Utah Copper the work of remodeling the Arthur plant is being pushed, and two more sections will soon be ready for operation, making a total of eight out of thirteen to be working on ore. The six sections which have been finished treat 5400 tons per day, so the eight sections will increase the capacity to 6000 tons. When the entire plant is remodeled, it will be able to treat upward of 9000 tons of ore per day. Any great increase in the output of the mine will require the purchase of additional equipment for the Bingham & Garfield railroad, which is now working to the limit of its present equipment. It is expected this provision will be made.

In contrast to the general increase in tonnage, the Yampa has closed down, pending different smelter arrangements. The Yampa has always played close to the ragged edge on profits, and about a year ago it closed down its smelter and began shipping to the A. S. & R. Co. plant at Garfield. The new manager, Mr. Moodie, was reported to be making money through economical mining and showing a margin of profit. Mr. Moodie left recently for British Columbia to take charge of a mine there for the same interests, and now the Yampa has been closed down. It is given out that the reason for the shut-down is that the smelter limited the Yampa to 300 tons per day, and that a larger tonnage was necessary to make a profit.

In Beaver county, the South Utah Mines & Smelters (formerly Newhouse) is steadily climbing the ladder. During November it shipped to the concentrator the largest amount in its history, 25,205 tons of ore, which yielded 2255 tons of concentrate averaging 8.28% copper, an extraction of 61%. The November production was 361,681 lb. of copper, 2742 oz. of silver, and 140 oz. of gold, compared with 299,807 lb. of copper, 1903 oz. silver, and 114 oz. of gold for November 1910. For October and November the production was 688,259 lb. of copper, 5461 oz. of silver, and 274 oz. of gold, as compared with 492,449 lb. of copper, 3300 oz. of silver, and 219 oz. of gold for the corresponding months of last year.

General Mining News

ALASKA

Prince William Sound

M. M. Reese, president and general manager for the Mayfield M. Co., is planning to construct a 5-stamp mill on the property, and to have the plant ready for operation in July.

ARIZONA

Gila County

The Inspiration Con. Copper Co., capitalized at $30,000,000 in 1,500,000 shares, has been incorporated at Augusta, Maine. The new company represents the consolidation of the Inspiration M. Co. and the Live Oak Copper M. & S. Co., and has combined reserves of 45,000,000 tons of 2% ore. The first plans included the Miami Copper Co., but after consideration of the ore reserve and other matters pertaining to the merger, the price of the Miami property was considered prohibitive and the company was not included. The principal figures in the consolidation were W. B. Thompson, president of the Inspiration company, and John D. Ryan, who recently purchased the control of the Live Oak.

Graham County

The report of the Shannon Copper Co. for the year ended August 31 shows a production of 263,975 tons of ore, against 311,456 tons the preceding year. During the period covered by the report 7645 ft. of development work was done, against 7373 ft. in 1909-1910. The new development opened up bodies of smelting and concentrating ore in the lower levels, but the extent of the reserves cannot be accurately estimated, states the report of the general manager, owing to the heavy nature of the ground. The yield per ton was 56.9 lb. of copper, against 53.56 lb. the preceding year. The company has been experimenting with its low-grade ore, of which it has between 1,000,000 and 1,500,000 tons, and which assays 2 to 2½% copper. It is believed the ore can be treated at a profit.

The cost of the copper was a trifle under 10c. per lb. at Clifton, and 11.57c. per lb. at New York. The income account of the Shannon-Arizona railroad shows receipts amounting to $96,081. The expenses amounted to $50,225, the operating profit being $45,856. The interest on bonds amounted to $36,000, leaving a balance of $9856 for the year, as compared with $4718 for the preceding year.

Mohave County

(Special Correspondence.)—The Grand Gulch M. Co., operating a copper mine in the northern part of this county, mined 625 tons of copper ore during the year, 325 tons of which was marketed. This is a carbonate ore, and that which was shipped sampled 31% copper. The ore was hauled 70 miles to the railroad at Moapa, Nevada. A branch of the San Pedro railroad is being built from Moapa to St. Thomas, a distance of 25 miles, and this branch is expected to have train service by next March. In anticipation of this the Grand Gulch M. Co. is hauling ore to St. Thomas to be shipped from there later. About 200 tons of ore of above named grade is now stacked there. The mine has been developed and is being operated through a 550-ft. shaft. W. P. Jennings, the company's manager, states that development and production are to be on a larger scale after the railroad is finished to St. Thomas, as this will reduce the distance of wagon haulage to 45 miles.

Salt Lake City, December 24.

Pinal County

The clean-up at the Ray Con. Copper Co.'s mill for November shows a yield of 68½% on ore assaying 1.75% copper, stated D. C. Jackling, general manager for the company, recently. The production, 2,650,000 lb. of copper, based on smelting at Hayden, would have cost 9c. per lb. No. 2 hoist and plant will be started in the near future. The fifth section of the mill is running smoothly.

CALIFORNIA

Calaveras County

The California Supreme Court last Wednesday handed down a decision awarding the Lightner M. Co. $27,000 damages against the Utica M. Co. for the theft of ore below the Lightner workings. The first suit was filed in 1902, and the jury in the Superior Court awarded the plaintiff company $54,000, which the higher tribunal found excessive, as it represented the gross value of the gold in the ore. The verdict of this week subtracts the cost of production. The Lightner mine was sold by Alice L. Eastland to the Lightner M. Co. in 1906 for $100,000. Trespass by the Utica was discovered in 1899, and after an investigation as to the amount of ore taken by the Utica miners, suit was brought in 1902. C. D. Lane of the Utica company and associates fought the suit bitterly. The ore taken amounted to about 12,000 tons. The Supreme Court overruled several exceptions to the lower court's findings, stating that as the Utica had "employed fraudulent means to conceal the extraction of the Lightner ore" the suit was not nullified through the statute of limitations, and that the evidence in the case was sufficient to dispose of the plea that no specific date when the ore was taken was named.

Fresno County

The production of the Coalinga oilfields for November amounted to 1,508,589 bbl. of oil, according to recent estimates. This was less than the October production by 46,985 bbl., but the average daily production was greater than that of October. The decrease in the month's production was due to the 30-day month.

Inyo County

A meeting of miners and prospectors has been called for January 24 at Bishop to organize the 'Prospectors Alliance of America'. The organization will protest against a proposed ruling to require all prospectors for minerals to take out a Government license.

The Skidoo Mines Co. in November treated 1192 tons of the company's ore and 144 tons of lessees' ore, although seven days' time was lost through the breaking of a camshaft. The bullion produced was valued at $9545, while the total receipts amounted to $15,909. Development expense was $938, and operation cost $7600, leaving a net profit for the month of $7372.

Kern County

A report from Randsburg states that the Four Ace M. Co. is shipping 15 tons of ore per day from the Santa Ana mine. The ore assays, on the average, $20 per ton, according to the report. Frank Wilson, of Butte, Montana, is having assessment work done on his claims near Randsburg.

Plumas County

The New York mine, near Greeneville, will be extensively developed in the near future. The property, which is a quartz mine, has been bonded to E. O. Lindblom, of San Francisco.

Press rumors affirm that a mill will be built in the Onion Valley district, at the Comstock group of claims. A report from Quincy quotes H. Kling, superintendent of the property, as saying that the company has developed a large body of ore assaying $5 to $20 per ton.

Sierra County

Press reports state that coarse gold has been found in gravel in a raise in the Haskell Peak mine. The adit is being driven to bedrock.

The Tightner Mines Co. has been incorporated to operate the well known Tightner mine at Alleghany. Abe Hall, of Grass Valley, will be in charge of the property, L. N. Wagner will be assistant superintendent at the mine, and C. C. Derby, of Nevada City, is to be consulting engineer for the company. The capitalization is $100,000, divided into 100 shares of $1000 par value. Among the incorporators are A. D. Foote, of the North Star Mines in Grass Valley; A. B. Foote, assistant manager of that property; C. E. Clinch, of Grass Valley; Edward C. Uren, George Scarfe, E. J. Rector, and C. C. Derby, of Nevada City;

J. M. O'Brien, of San Francisco, Abe Hall, Robert Bedford, and Carl P. Jones, of Grass Valley, and W. H. Martin, of Nevada City.

COLORADO

Clear Creek County

(Special Correspondence.)—The production from the upper Clear Creek district for 1911, according to figures at hand, amounts to $51,890. Moscript & Co., leasing at the Capital mine, are stoping on a 6-in. streak of yellow copper that mills $55 per ton in gold and silver. The shoot is showing for 100 ft. Work has been resumed on the Allen property on Griffith mountain. H. Mueller is owner. John Bowen, Sr., has taken a lease on a block of ground on the Gambetta mine. Stoping is under way on an 8-in. streak of 52% zinc ore. The new plant of machinery at the Bellevue Hudson mine on Columbia mountain is in position. G. W. Boyce is manager of the property. A streak of ore 4 in. wide has been found at the 360 ft. level of the American Sisters mine. The ore assays as high as 3000 oz. silver and 2.40 oz. gold per ton. J. J. White is manager. Work is in progress on the Buffalo property on Alpine mountain. The lower adit is in 550 ft. William Hunt is owner. Clair & Co., leasing on the fourth level of the Smuggler mine, are stoping on a 6-in. vein of galena ore that mills 378 oz. silver and 36% lead per ton. The Homestake adit on Lincoln mountain has been driven 600 ft. A new vein is being penetrated. A. L. Stephens is manager for the company.

Georgetown, December 23.

ELKTON MINE, CRIPPLE CREEK.

Teller County (Cripple Creek)

In a report for the first half of December it was stated that the flow from the Roosevelt drainage adit was 8750 gal. of water per minute. During the period the main bore was driven 127 feet.

The Modoc G. M. Co., owning the Modoc mine on Battle mountain, paid a dividend of 1c. per share December 20. The property was the scene of one of the richest discoveries of sylvanite ore made in Cripple Creek district during the past year.

H. P. Reiton, of Cripple Creek, has taken a lease on the Amanda and on the north half of the Bogart properties. The Home claim, Ironclad hill, has been leased to Oscar Fogleman.

The Elkton Con. M. & M. Co., with its concluding ½c. monthly dividend for December, has paid a total of $225,000 in dividends in 1911.

The Granite G. M. Co. on December 20 paid a dividend of 2c. per share, making a disbursement of $20,000. The properties of the company are operated by lessees. It is said that the December production of the Granite company's mines will be about 2000 tons of ore.

The W. P. H. shaft of the United G. M. Co. is to be sunk an additional 100 ft. It now is 650 ft. deep. It is under lease to Fogleman & Roach.

The 101 Mining Co. has installed a friction hoist at the Requa Savage shaft. Development is now limited to the upper workings, but sinking will be commenced in a few weeks. Sub-leases may be granted for blocks of ore near the surface. Charles Crowder is manager for the company.

The production of the Jerry Johnson mine, Ironclad hill, for December, will be about 45 cars of ore, according to the estimate of Frank Caley, lessee.

The Gold King company, which owns the first mine discovered in the Cripple Creek district, according to report, has paid a dividend of 3c. per share, making a distribution of $20,000. The company is a close corporation. The property is operated by Owen Roberts, a lessee, who took hold of it after it had been declared 'worked out'.

IDAHO

Shoshone County

Silver lead ore recently was found at the Edna May mine, in the Coeur d'Alene, within half a mile of the C. M. & S. P. railroad. The orebody is developed by a 40-ft. adit and a 100 ft. adit.

Plans have been made for a gravity railroad to take ore from the portal of the new adit of the Stewart mine to the railroad. The 'empties' will be brought back by motor. A 'switch-back' was considered, but discarded for the new plan. The adit is in about 200 feet.

MONTANA

Silverbow County

The directors of the Parrot Silver & Copper Co. have voted to distribute to shareholders *pro rata* the 90,000 shares of Anaconda Copper M. Co.'s stock which was accepted as payment in the sale of the entire property of the Parrot company to the Anaconda company. The Anaconda shares have been practically the sole asset of the Parrot company. After the sale, which was before June 1911, W. F. Walt and Lewis Foss of Boston, controlling 1210 shares, brought suit in the Federal court to have the sale set aside. The directors believe that the minority stockholders should no longer wait for a settlement of the litigation. There are 230,000 Parrot shares, so the holder of ten shares of Parrot will receive slightly less than four shares of Anaconda, with a small amount of cash. The Amalgamated was the principal owner of Parrot at the time of the sale.

The Tuolumne new surface plant is to be ready for operation about the first week in January. The steel headframe and hoist are now in position. It is said the company will increase its output to possibly 250 tons per day.

The new Raven compressor recently purchased in Salt Lake is in position, and the tests made show that it is in good working order. In the next few days work will be started to unwater the lower levels of the mine, but inasmuch as the water is over 300 ft. deep, some time will be required to remove all of it. It is proposed to put a force of men at work developing the lower levels as soon as the water has been pumped out.

Mining men, including officials of the Anaconda company, do not fear trouble next spring with the Miners' Union when the contract relating to the wage scale expires. This contract, entered into nearly five years ago through the efforts of John D. Ryan, provides that when copper was 18c. or over, the miners should receive $4 per day, and that when it dropped below that figure, they were to receive $3.50 per day. For quite a long time copper was above 18c., but it was not until it dropped below 17c. that the Amalgamated dropped the rate of wages to $3.50, according to agreement. The Miners' Union is a very conservative organization, while the Anaconda company, on the other hand, has always shown its preference for union labor. The statement sent out from this city that there was a possibility of the company declaring in favor of non-union labor has not a shadow of truth in it, according to people who should be in a position to know. The Anaconda company is to start about the first of the year to sink the shaft of the St. Lawrence mine from the 2300-ft. level to a depth of 2600 feet.

NEVADA

Esmeralda County

Better progress than was expected has been made in enlarging and timbering the St. Ives shaft of the Goldfield Merger Mines Co., controlled by the Goldfield Deep Mines

Co., of which J. Ross Clark, brother of William A. Clark, of Montana, is president. The plans of this company include sinking a shaft 2000 ft. deep. It has been enlarged to three compartments, each 5 by 4½ ft. in the clear, to a depth of 470 ft. and the timbers framed to fit those of the fourth compartment. The timbering is nearly finished, and sinking will be in progress by the first of the year. The new hoisting plant, compressor, and steel head-frame, to be installed early in the coming year, will be among the largest and most modern in the entire country, and sinking will progress with all possible expedition.

In the Diamondfield part of the district the Goldfield-Belmont company has exposed a good orebody in the new winze, sunk 50 ft. below the 300-ft. level, and will resume stoping at this point and shipping the product. The winze is 750 ft. distant from the main shaft. A supplementary electric hoist is in use at the winze, which will continue to further depth. It is probable that the raise from the 300-ft. level, being driven to connect with a winze from the 150, will be continued to connect with the surface in order to supply a working shaft at this point. There is no water in the mine at present depth. The Vernal, adjoining the Belmont on the north, and developing a continuation of the Belmont vein, has some excellent ore on the 50-ft. level, assays running from $40 to $190 per ton, and is driving from an old lease shaft near the Belmont boundary to connect with the future main shaft, about 75 ft. deep, near the centre of the Vernal claim. Lessees who recently began work on the Diamondfield Black Butte, from the main company shaft, are driving northeast from a new station on the 250-ft. level and are believed to have penetrated the casing of the famous Quartzite vein, from which a production of nearly $500,000 worth of rich shipping ore was made in the early years of the camp's life. The vein dips away from the shaft and this level is 100 ft. vertically, and a considerably greater distance on the incline of the vein, below the sill-floors of the deepest of the old stopes. Other lessees working on the west side of the butte have exposed seams of rich ore, carrying gold and silver, on the 100-ft. level, and are unwatering the shaft in order to drive for the vein 100 ft. deeper. Work will be started soon on a new lease on the east end of the Daisy, which has the southern extension of the Belomnt vein and where small quantities of rich ore have been mined recently by lessees.

Humboldt County

(Special Correspondence.)—The Indian National company is driving a cross-cut on the Silver Slipper lode, and expects soon to intersect a rich shoot exposed in the upper adit. Good ore is reported in the lower workings. The Great Equator company has uncovered a promising lode, and is driving in hopes of reaching the rich Charlestown vein. This property lies north of the National Mines and Indian National group. Developments at the National Mines estate are understood to be attended with the usual good results. This company has disbursed dividends amounting to $225,000 in 1911, or a total of $570,000 since organization. The ore content is principally gold. Mrs. Emma Stith has discovered a promising prospect north of National. The vein is said to be strong. Officials of the Sheba mine recently arrived from Houghton, Michigan, to examine the company's holdings, and it is rumored that development will be conducted on a larger scale. Adamson & Turner are working steadily on the Recall property, four miles from Winnemucca, on the north side of Winnemucca mountain. A small percentage of the ore is stated to be high grade. Munna, Polin, and associates have resumed activities at their claims, a few miles above Paradise. The recently burned cyanide plant has been replaced by a new one. Lessees on the Signal Peak group, Seven Troughs district, are shipping ore from near the surface. A 1500-ft. adit is being driven to cut the vein at depth. The ore is said to assay $50 to $75 per ton. The quartz is sent to the Darby custom mill. The interests controlling the Darby mill have taken a bond and lease on the Mazuma Hills group. The incline shaft is down 400 ft., and cross-cutting to the vein is under way. Stahl Bros. have bonded several properties in the north end of the Seven Troughs field. They recently opened a vein of rich quartz on the Golden Horseshoe claim. Sinking is under way.

Winnemucca, December 22.

Ore reported to be exceptionally rich in free gold was found recently in a vein 1 ft. wide on the Seven Troughs Coalition M. Co.'s property. The new vein parallels that now being developed in the Friedman winze.

In a preliminary annual report to stockholders, L. A. Friedman, general manager for the Seven Troughs M. Co., states that during the year the Florence M. & L. Co. produced from the Seven Troughs property 887 tons of ore, principally from stopes adjacent to the sixth level. To prospect the property at depth, the Quinton M. Co., acting in conjunction with the Florence company, straightened and retimbered the Fairview shaft and did other development work. Several improvements were made in the surface equipment. A recent run at the Darby mill on 60 tons of ore from the sixth level and 72 tons of low-grade ore was made, but the returns have not been published. High-grade silver ore was mined on the 200-ft. level of the Florence workings early in the year, but at present the land about the Florence shaft practically has been abandoned.

Good ore has been found in the adit of the National Mines Co. at the south end of Radiator hill, according to a recent report from Winnemucca. George Stowe is superintendent of the property.

Lincoln County

Newspaper reports from Pioche state that the Prince Con. M. Co. has started grading for a railroad to its property. While the road, which will cost between $100,000 and $140,000, and which is to be completed by May 1, 1912, ostensibly is an undertaking of the mining company, it eventually will become the property of the Los Angeles & Salt Lake railroad.

H. C. Parker and Patrick Friel have taken a lease on the Bamberger property, adjacent to the Day mine at Jack Rabbit, and a siding will be built where the ore can be loaded for shipment to Pioche on the Pioche Pacific railroad.

Nye County

(Special Correspondence.)—The Jim Butler company is planning development of the Fraction vein, following the agreement with the Tonopah M. Co. over apex rights. Work ceased on a portion of the vein about four years ago, as it was then apparent that litigation would probably develop. The orebody has proved one of the best in Jim Butler ground, and its further development will be watched with interest. The main shaft of the Belmont is 70 ft. below the 12th level, with the winze 110 ft. farther down, on the dip of the vein. All the ore is stated to be high smelting grade. As depth is gained, the ore appears to be assuming a smelting character. The new mill is making rapid progress. Most of the milling equipment has been installed in the new MacNamara mill, and the electrical machinery is expected within a few days. If present favorable conditions continue, the plant will be in operation early in the year. The mill has 10 stamps. According to advices from Pioneer, the Tobin brothers of Denver have recovered control of the Pioneer Consolidated group and are arranging for vigorous work. The property is credited with a production of $600,000 in two years. The reopening of the group means a brisk season for the Pioneer district. Manhattan advices report good progress on the mill of the Associated company, and it will be in operation about March 1. Placer mining on the west side of the district is active, and much bullion is being sent out. The Big Four is reported to have opened rich ore on the 400-ft. level. A cross-cut has been started to determine the width of the vein.

Tonopah, December 22.

White Pine County

The Nevada Con. Copper Co.'s report for the 13 months ended October 31 gives the net earnings of the company for that period as $2,298,759. The dividends paid amounted to $2,997,505. The total receipts, $6,276,477, less the dividend disbursements and $981,255 for 'ore extinguishment' left a balance on hand of $2,594,717 in undivided profits at the close of the period named.

A meeting of the Boston Ely company will be held in the near future to consider increasing the capitalization to raise money for development, or the assessment of 50c. per share on the stock.

Unconfirmed rumors are to the effect that the Giroux company's ore is to be treated at the Nevada Consolidated concentrator at McGill. It is reported that a contract has been signed in New York for the concentration of the Giroux sulphide ore at the McGill plant, and also for the smelting of concentrate and for the treatment of a large amount of direct smelting ore which soon will be shipped from the Alpha. The report has been received with enthusiasm in the district as indicating that the Giroux would reach a producing basis at least by next April.

NEW MEXICO

GRANT COUNTY

The first shipment of the Chino Copper Co.'s mill is producing about 40 lb. of copper per ton of ore treated, according to an interview with D. C. Jackling, general manager for the company, at Salt Lake. The second section was to have been in operation before New Year's, and the third section will be ready early in January. The structural steel for the fourth and fifth sections, recently decided on, is being raised. Mr. Jackling has recently inspected the plant personally.

CHINO CONCENTRATOR.

UTAH

"To protect the interests of stockholders of Nevada-Utah M. & S. Corporation", F. D. Pavey and associates have organized a stockholders' protective committee. The committee invites deposits of stock. The Security Transfer & Registrar Co., 66 Broadway, New York, will issue transferable certificates of deposit for the stock, which must be deposited on or before January 5. The company owns property in Beaver and Salt Lake counties, Utah, and Lincoln county, Nevada.

BEAVER COUNTY

Moscow, of Beaver county, has come to the front with its second dividend in three months, of $8000. The property is shipping regularly about $6000 worth of ore per month.

The fight for the control of the old Horn Silver, at Frisco, Beaver county, has resulted in a victory for the 'insurgents.' The new board consists of E. B. Critchlow, M. C. Morris, H. S. Young, Alexander B. Simonds, Jacob Neadle, Edward E. Olcott, William R. Britton, and Charles Brennermann. The mine, which is one of the pioneers among Utah producers, is now shipping about 1000 tons of ore per month, much of it under leases. In 1910 its receipts were $147,152 and the net profit was $47,357. It has paid a total of $5,642,000 in dividends.

JUAB COUNTY

The Tintic Leasing Co. is shipping about 10 cars of ore per month from the Galena King mine, Stockton district, where it started operation last February. Development is active at the Miller lease, where shipping grade ore is being mined.

The Iron Blossom Con. M. Co.'s report for the year ended December 1 contains a hope that 'some one' will undertake the construction of a mill for the district, as many mines have ore which under present smelting charges it is not profitable to ship. Receipts for the year, according to press accounts, amounted to $269,175, and disbursements to $298,017, of which $200,000 was for dividends. Since the report a $50,000 disbursement was made in the Christmas dividend.

The electric hoist of the Selma property, in the North Tintic district, is working smoothly, and the shaft is being sunk at a rate of about 6 ft. per day.

A contract has been let for the construction of a 2600-ft. tramway at the Eva property in the Nebo district.

Ore shipments from the Tintic district last week totaled 130 cars.

Ore assaying about 30 oz. silver and $4 gold per ton was discovered last week in the No. 3 workings of the Iron Blossom mine. Further development of the orebody is said to have shown improvement in grade. The discovery was made in a raise about 40 ft. above the 600-ft. level.

About 100 tons of ore was shipped last week from the Beck Tunnel property. It is reported that the recent assessment of Black Jack stock will give a working capital of about $5000 after all debts are paid, and that development may be resumed. Sinking of the main shaft at the Eagle & Blue Bell mine will be started by January 10.

Dragon Consolidated, of Tintic, long known as a shipper of iron flux for the smelters, will soon enter the lists as a producer of silver-lead ores. The Knight interests, which control the Dragon and the Iron Blossom, have followed the Iron Blossom orebodies into Dragon ground. Shipments will be made through the Iron Blossom workings.

SALT LAKE COUNTY

The United States S., R. & M. Co. has declared its regular quarterly dividend of 1.75% on preferred and 1% on common stock, payable January 15. The company is purely a securities-holding corporation, controlling the United States M. Co., the United States Smelting Co., and the Mammoth Copper M. Company.

Newspaper reports regarding the Michigan Utah Consolidated, the new holding company of the Utah Mines Coalition Co., City Rocks, Grizzly, and Copper Prince, are to the effect that of the capital stock, one-half, or 500,000 shares, will be retained in the treasury. Of this amount, 250,000 shares will be reserved for conversion of a bond issue of about $625,000.

Efforts to get the old camp of Stockton to 'come back' are meeting with partial success. The Bullion Coalition, which is a consolidation of the old Honerine, Honorine Extension, Honerine Tunnel M. Co., Bullion, and Honorine Western, is paying expenses while searching for additional orebodies. The company is working under the lease system, and is shipping over $12,000 worth of low-grade silver-lead ore per month.

The Utah Copper Co. in November produced 9,117,961 lb. of copper, against 8,660,729 lb. in October. During the first quarter of 1911 the company produced 25,851,455 lb., during the second quarter 24,469,812 lb., and during the third quarter of the year 21,296,709 lb. of copper.

SUMMIT COUNTY

The directors of the Daly West company have declared the usual dividend of 30c. per share, also an extra of 15c., both being payable on January 10, to stockholders of record on December 30. This calls for the disbursement of $81,000.

UTAH COUNTY

The Knight Investment Co., of Provo, which controls many Utah mines, has branched into Colorado. By a deal effect at Salt Lake City, it has acquired 510,000 out of the 1,000,000 shares in the Rico-Wellington company at Rico, Colorado, and has assumed the management.

TOOELE COUNTY

The Cliff M. Co. has declared a dividend of 10c. per share, payable January 2 to stockholders of record December 20. This company owns property in the Ophir district and employs about 75 men. The orebody has been developed for 1500 ft. The main office of the company is at Duluth, Minn., but the manager, Grant Snyder, resides in Salt Lake City.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The Republic Mines Corporation has increased its ore shipments during the last three weeks to two carloads per day, and the smelter returns received show an average of $7.65 net per car. The appearance of the mines indicate a further increase in the near future. In the Lone Pine an immense body of high-grade ore is being opened up on the 400-ft. level. The main inclined shaft on the Surprise mine has been deepened 100 ft. since sinking was resumed. From the cross-cut in the 400-ft. level drifts have been driven each way on the vein. From a point 30 ft. south from the cross-cut a rich body of ore was found, the assays running as high as $342 per ton. The stope on the 600-ft. level is up about 115 ft. The ore-content is changeable, the assays ranging $4 to $398 per ton.

At the Black Tail mine the work at present is confined to sinking the shaft, which has gained 40 ft. in depth. The San Poil Consolidated holds leases and bonds for five years, dating from February 2, 1911, on the San Poil, North San Poil, Snowstorm Fraction, Baby Fraction, and Trade Dollar claims, and has taken up the bond on the North San Poil for a consideration of $33,000, saving $15,500 in the transaction.

The Meteor M. Co. promises to put on a large force of men at the Meteor mine, at Covada, after January 1.

Republic, December 22.

STEVENS COUNTY

(Special Correspondence.)—Work has been resumed by the Valley Dew M. Co., in the Orient district. The Orient Gold Mines, Ltd., has sunk a shaft at the White Elephant mine nearly 100 ft. in ore which assays as high as $50 per ton. The shaft will be continued to 125 ft., at which depth a level will be opened. The shaft recently has been equipped with new hoisting machinery. About 300 ft. up the hill from the shaft, on a separate vein, a body of rich gold-bearing ore has been developed to a width of 6 ft. and is widening with depth.

The Ben Venue mine, near Meyers Falls, has been developed to a depth of 145 ft. and has produced six carloads of ore, none of which assayed less than $40 per ton. A recent shipment of 20 tons assayed $60.45 per ton. From the profits derived from the entire yield a surplus is left for the purchase of machinery.

The old Dead Medicine mine, on Clugston creek, in the Colville district, has been reopened by the Clugston M. Co. In the last year and a half an adit has been driven about 700 ft. which has run into a full face of ore that assays $12 to $70 per ton. The discovery was made at a depth of about 450 ft., 200 ft. below the old workings.

The south drift in the United Copper mine, at Chewelah, has penetrated 220 ft. in shipping ore, having a width of about three feet at the face which averages nearly $100 per ton.

Orient, December 23.

CANADA

BRITISH COLUMBIA

S. G. Blaylock, superintendent for the Canadian Con. M. & S. Co., is quoted as saying that the smelter at Trail is running at full capacity in its lead department, which can treat 250 tons per day. The copper department has a capacity of 1500 tons of ore per day, but never has been operated to a greater capacity than 900 tons, at which rate it is running at present. While the smelter has been run at an increased cost during the past few months, owing to the necessity of importing coke from Pennsylvania, the next annual report will show a gain both in profit and in volume of business, according to R. H. Stewart, general manager for the company. Mr. Stewart predicts an increased production by the Slocan district.

Late reports from Boston state that the Granby company in the near future will have four of its eight furnaces at the Grand Forks smelter in operation. The final payment for the Hidden Creek property, amounting to $200,000, was due December 15, but was made some time ago at a good discount. There remained to be paid $25,000 to Mr. Rogers, engineer for the company, who owned an interest in the property. He relinquished his interest for 1500 shares of Granby and $50,000 cash. Mr. Hodgens, holder of the majority interest in the Hidden Creek company, was paid $400,000.

ONTARIO

The report of the Coniagas Mines, Ltd., for the year ended October 31 shows a production of 3,789,274 oz. of silver, against 1,929,531 oz. for the preceding year, which exceeded the production of the year before. It is reported that the development of new orebodies has almost equalled during the year the value of the silver produced. During the year 52,230 tons of ore averaging 36.3 oz. silver per ton was milled. A total of 1418 tons of concentrate, containing 1,643,616 oz. of silver, was shipped during the year, together with 619 tons of ore. With the exception of one car of low-grade ore, all ore was shipped to the Coniagas Reduction Co. at Thorold.

The drill-hole on the Pearl Lake property has reached a depth of 1300 ft. and has penetrated ore assaying as high as $21.60 per ton.

MEXICO

GUANAJUATO

The work of cross-cutting from the deep Nueva Luz shaft for the mother lode of the Guanajuato district will be resumed in December, it is now announced. It was expected to cut the lode as long ago as last February, but the Proprietary Mines Co., which is financing the Nueva Luz, gave its attention to the completion of the reduction plant at the Tajo de Dolores, another Guanajuato holding, and the Nueva Luz work was delayed. Lately shaft-timbering has been in progress, and air lines have been put in to facilitate the work of cross-cutting.

SINALOA

Orders have been placed for a new power-plant at the famous Guadalupe de los Reyes mines in the Cosalá district of Sinaloa, and it is expected to make a big reduction in operating costs. For a number of years the company has been paying out an enormous sum annually for wood for the present steam plant. Formerly Guadalupe de los Reyes paid dividends of ₱1,000,000 yearly, but of late years the net earnings have been small. In the new plant, which will be ready by May of next year, charcoal gas-producers will generate current for the mines and reduction plant.

PHILIPPINE ISLANDS

For conducting mining operations in Mindoro and Bulacan and at Monte de Oro in Rizal, says the *Daily Consular Report,* articles of incorporation have been filed by the Rizal iron mining company, capitalized at ₱1,000,000. It will have its headquarters in Manila. The company will undertake the mining of iron, besides gold mining at Monte de Oro.

ARGENTINE REPUBLIC

A report from R. M. Bartleman, consul-general at Buenos Aires, says that the Argentine president has recommended to Congress the appropriation of ₱2,000,000 ($850,000) for the exploitation of petroleum in Comodoro Rivadavia. The recommendation says that three test wells there yielded not less than 10 tons each per day, and ₱10 per ton is thought a low price, as a ton of petroleum is equal to two tons of coal, of which the market price is ₱20 per ton. The Ministry of Agriculture supplied for the locomotives of the railway to Lake Buenos Aires 2000 tons of petroleum to take the place of 4000 tons of coal which had cost ₱40 per ton.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS

RIGHT OF LIFE TENANT TO SELL MINERAL

The owner of a life estate in land has no power to sell any mineral rights therein, as such a power would give to the life tenant the right to destroy the life estate of the remainder man.

Rittenhouse v. Porter, (Kentucky) 128 Southwestern, 288. May 1910.

CONVEYANCE OF MINING LAND IN TRUST

The fact that a grantor conveyed certain mining land in trust for certain beneficiaries, intending by such conveyance to part with all his interest in the land for the exploitation of the mine, the interest of such beneficiaries in the land did not terminate from the fact that the mining enterprise was a failure, but the beneficiaries held an interest in the land for whatever value it in fact possessed.

Glynn v. Maxfield, (New Hampshire), 76 Atlantic, 196. May 1910.

RESERVATION IN GRANT OF COAL—LIABILITY FOR BREACH

A reservation in a grant of the coal under certain described premises by which the grantor reserved and excepted one-quarter of an acre on which his barn was situated was sufficiently certain, and the grantee was bound to leave the one-quarter acre of coal so excepted for support, and the grantor was entitled to recover the value of the coal taken from such quarter acre; he was entitled to damages in double the value of the coal in the vein immediately before the taking under a statute of Iowa providing any mine operator or one who takes coal without permission from adjoining land shall be liable in double damages therefor and for all expenses caused thereby.

Stewart v. Colfax Consolidated Coal Co. (Iowa) 126 Northwestern, 449. May 1910.

LIABILITY FOR INJURY FROM BLASTING—INDEPENDENT CONTRACTOR

A railroad company was held liable for an injury caused by negligently conducting blasting operations near the residence of the complainant. The fact that the work was done for the railroad company by an independent contractor was not sufficient to exempt the railroad company from liability where it appeared that the company by its own servants had first attempted to perform the work, and knowing its performance in the manner attempted would injure complainant, the fact that it procured an independent contractor to conduct the work in the same negligent manner was sufficient to make the railroad company liable.

Hunter *v.* Southern Railway Co., (North Carolina) 68 Southeastern, 237. May 1910.

INJUNCTION TO COMPEL CITY TO EXTINGUISH A BURNING MINE

A court properly refused to issue a mandatory injunction to compel a city to extinguish fires in an anthracite coal mine, as there is no method in common and ordinary use which can be used to extinguish such a fire. Whether such a fire can be extinguished at all or not is a question of mining engineering, and a question of which a municipality as such would have no knowledge, and in the absence of proper apparatus it would require an outlay of a vast sum before any intelligent effort could be made to extinguish such a fire, and without any assurance that such an effort would be successful. It is a matter of common knowledge that mine fires in the anthracite coal regions present baffling questions of mining engineering, most difficult to deal with and at times impossible to grapple with successfully. The principle under which municipalities may be compelled to abate nuisances upon a public highway or arising out of their own neglect of duty, does not apply in such cases.

Cameron *v.* City of Carbondale, (Pennsylvania) 76 Atlantic, 198. May 1910.

Company Reports

TOMBOY GOLD MINES CO., LTD.

The report of this company for the year ended June 30, 1911, shows a net profit of £63,861. Two dividends of 2s. each were paid, on December 15, 1910, and June 30, 1911, resulting in the disbursement of £60,000. After deducting the income tax, commission to the general manager, John Herron, and depreciation, there is a balance of £121,179, as against a balance of £57,318 carried forward the preceding year.

The ore treated during the year amounted to 116,222 tons. The bullion production was valued at $781,324. The cost of production was $509,057, leaving a net profit of $272,267. The net profit of $309,375 is reached by adding to the foregoing the $37,108 received from other sources. The ore reserve was estimated as 427,000 tons, as against a reserve of 441,600 tons in the previous report.

To prove the mine in depth, the shaft was sunk to the 2100 ft. level. For at least 100 ft. at that level, states the report, the vein has maintained its average width and grade. No important changes have been made in the plant and equipment, excepting certain alterations incident to the gradual increasing of the concentrating plant's capacity. The report states that the title to the Revenue Tunnel property, purchased in July for $400,000, has been found good, and the last payment was made November 1. Treatment of ore from the new property will be commenced late in December. There have been some changes in the reduction plant, and one of the improvements made by the Tomboy company on the new property was the construction of a tramway from the adit to the mill.

STRATTON'S INDEPENDENCE, LTD.

During the year ended June 30 this company's mill treated 109,800 tons of ore, as against 68,711 tons during the preceding year, as the mill has been doubled in capacity, in accordance with the consulting engineer's report for 1910, and can handle 10,000 tons of ore per month. The mill's net profit for the year, £12,615, shows an increase of £7155 over that for the preceding twelve months. The production of concentrate and bullion amounted to £45,788, and the expenses to £33,173.

The mine account shows 2752 tons of ore sold for the company and 15,633 tons for lessees, for £8636 and £94,364, respectively. The cost of freight and treatment for the company's ore amounted to £2824 and £21,927 for the lessee's ore, leaving for the two accounts net proceeds of £5812 and £72,436. Of the latter sum the company retains 39.77%, or £28,813, as royalty and charges on profits.

The mine and mill profits, as stated, together with rents, interest, and commission, and after deducting all expenses including taxes and the maintenance of the London office, gives the total net profit for the company as £21,006.

One 10% dividend was paid, on November 29, 1910, resulting in the disbursement of £12,500. The directors recommended in the annual report the payment on November 16 of an interim dividend of 10% from the balance left, £9437.

The main levels of the mine are now reopened, and the 'caved area' has been repaired for active mining. The most valuable ore found below the third level in the Washington vein was discovered on the ninth level, where the vein is a foot wide and assays on the average 3 oz. per ton.

The mine output has exceeded the forecast of the consulting engineers and managers, Philip Argall & Sons, and gratification is felt from the fact that the estimated working profit of $10,000 per month has been realized from the time active milling was commenced in April 1909. Milling cost and production estimates also have been fulfilled. In the year just closed, for the first time, the mine produced low-grade ore which was treated in the company's mill. During the latter part of the year all refuse from the ore-house was treated in the mill.
